
Leaves, flowers, fruit, root, &c., of the Jalap plant.

With reference to the foregoing question as to *Convolvulus Jalapa*, Mr. J. Tyerman, of Torquay, writes to the *Garden* as follows:—"There is a plant of it in the Botanic Gardens at Liverpool, where it has been for the last fourteen or fifteen years, growing on a bed of gravel, the roots being about the size and shape of the double Cocoa nut. I do not think it has ever been tried in the open ground; perhaps the curator (Mr. J. Richardson) will possibly act on the suggestion, and give it a trial, and report the result. *Exogonium Purga* matured seeds with me this season for the first time; these are now in the hands of Mr. Thompson, of Ipswich, and I have no doubt that it has done so, and much more freely, in the College Botanic Gardens at Dublin, where both Mr. Ellacombe's and my own plants originally came from, nine or ten years ago. Both the Jalap and the Scammony grow luxuriantly with me, and I originally intended to recommend their cultivation on a large scale in this country for medicinal purposes; but I find that although they grow freely, and produce, like the common Bindweed, abundance of fleshy root-stems, from which they may be readily increased, they produce but slowly the tuberous roots from which the active property is extracted, and those are very deficient in resin, compared with prime imported samples. Judging from my short experience, it would require from four to six years to fully mature a crop, which would render it impossible in this country."

ZYMOTIC POISON.*

BY J. DOUGALL, M.D.

(*Concluded from page* 526.)

Dr. Bastian, in his experiments in proof of spontaneous generation, used various strong infusions, chiefly of hay and turnip, these being highly suitable for the existence of bacteria, etc. A portion of the fresh infusion is put into a flask and boiled for ten minutes, so as to destroy any minute organisms present, these being killed by a temperature of 212° Fah. During ebullition the neck of the flask is heated and hermetically sealed by the blowpipe, the bending inwards of the red hot glass showing a partial vacuum within. The bulb of the flask is then immersed in a water-bath, maintained at a temperature of 80° to 95° Fah. The result is that in the great majority of cases, after the lapse of some hours or days, the fluid becomes more or less turbid, and when examined by the microscope is found to contain bacteria and other allied forms. Dr. Bastian says he has taken organisms from flasks that had a few weeks before been hermetically sealed and heated for a variable time to temperatures ranging from 260° to 302° Fah. He therefore concludes, and I think fairly, that these organisms must have arisen *de novo* from the fluid in the flasks. Now, here are two theories equally striking, and both founded on experimental evidence, and while it is difficult to arrive at any other conclusion from Dr. Bastian's experiments than that life may spring from dead matter, there is also some difficulty in rejecting those of M. Pasteur, which, he thinks, prove that all life is derived from previous life. Possibly microzymes arise *de novo*, and also propagate biogenetically. The fact, however, remains that minute organisms are present in all putrefying solutions, whatever way they get there, and while the germ theorists assert they are the cause, there are others who maintain they are the result of putrefaction; the former also consider their *rôle* as malignant, and the latter as benign. The chief points

* A lecture delivered before the Glasgow Chemists and Druggists' Association.

adduced to show that bacteria, etc., are the cause of putrefaction, and fungi the source of many plant diseases, are—1st, Their presence in all putrefying fluids. 2d, Their absence in all fluids not putrefying. 3d, It is asserted that many diseases both of animals and plants are caused by living organisms, such as animal parasites and fungi. The opponents of this theory hold that these organisms are the result of the conditions of their habitat, and their concomitants. 1st, Because whether bacteria or fungi, they are only found on the parts of animals or vegetables with lowered vitality, or in their dead tissues. 2d. By increasing the vitality, or antisepting the dead tissues, they disappear. 3d, Contagious virus is destitute of the qualities of any known vegetable or animal parasites. 4th, No specific virus can be made to yield any specific organism. 5th, When microzymes appear in infective matter it ceases to infect. The first set of these propositions imply that the functions of microzymes are hurtful, while in the second set a benign *rôle* is attributed to them, and I think rightly. Professor Owen, with that wide grasp of intellect which marks all his works, and in that ornate diction with which he clothes all his conceptions, tells, in regard to the uses of infusoria, what may well be called "a fairy tale of science." "Consider," he says, "their incredible numbers, their insatiable voracity, and that it is the particles of decaying vegetable and animal bodies they are appointed to devour and assimilate. Surely we must in some degree be indebted to those ever-active invisible scavengers for the salubrity of our atmosphere. Nor is this all. They perform a still more important office in preventing the gradual diminution of the present amount of organic matter upon the earth; for when this matter is dissolved, and suspended in water in that state of comminution and decay which immediately precedes its final decomposition into the elementary gases, and its consequent return from the organic to the inorganic world, these wakeful members of nature's invisible police are everywhere ready to arrest the fugitive organized particles, and turn them back into the ascending stream of animal life. Having converted the dead and decomposing particles into their own tissues, they themselves become the food of large infusoria and of numerous other small animals, as the rotiferæ, which in their turn are devoured by larger animals, as fishes, and thus a pabulum fit for the nourishment of the highest organized beings is brought back by a short route from the extremity of the realms of organic matter." It would take too much time to discuss this part of our subject further. The points I have noticed are among the chief ones of the germ theory, and I consider there is a large balance of evidence proving that bacteria and fungi in dead matter, also the various animal and vegetable parasites of living organisms, are absolutely non-zymotic, the result and not the cause of the morbid conditions of their habitat; a similar conclusion having also been recently arrived at, by a commission appointed by a foreign government to inquire into the cause of the grape disease.

I now come to consider the physical theory. This theory, first propounded by Liebig, regards putrefaction as "a transformation or new arrangement of the atoms of a compound yielding two or more new groups, and caused by contact with other substances, the elementary particles of which are themselves in a state of transformation or decomposition. It is a communication, or an imparting of a state of motion, which the atoms of a body in a state of motion are capable of producing in other bodies, whose elementary particles are held together only by a feeble attraction."

Now, according to this view, that which is intercepted by the cotton-wool, and the bent tubes of the flasks already noticed, are not microzoa, but portions of dead organic matter in a state of transformation or decomposition, and these exist everywhere in the atmosphere near the earth's surface. In a pencil of solar rays entering a dark room by a hole in the shutter, myriads of floating particles are seen, which have been proven organic. Professor Tyndall has imitated this phenomenon very successfully in a beautiful experiment. A powerful beam of electric light is shot across a darkened space which shews the air to be a mere stirabout of extremely minute particles. If a person breathe directly into this light, the particles are much agitated and increased for the time. But if the breath be blown upon it through a tube with one end covered by cotton-wool, or if a red-hot iron ball be held close below it, in the first instance a black band cuts the beam in two where and when the breath meets it; and, in the second place, one or more inky fluctuating zigzag blots appear and disappear transversely in the beam immediately above the ball. Professor Tyndall has satisfactorily demonstrated that optically pure air is black, and these bands and blots are considered as such. Air from the lungs and the air of a room contain particles of watery vapour, and of organic matter. When the breath is blown through cotton-wool, it arrests them, while those floating above a red-hot ball are rarefied and burnt. Hence the transient black bands and tortuosities in the electric beam. Now, I have frequently examined, microscopically, the cotton-wool used in Pasteur's experiments to filter these particles, and although a very few bodies resembling sporules and diaphanous cells were found, yet the greater quantity of the particles adhering to the fibres were polymorphous, or amorphous, opaque, or semi-opaque, with ragged edges, and of various sizes, and presenting no signs of organization, and all the aspects of organic *débris*.

Believers in the physical theory thus hold that putrefaction is not caused by, and zymotic poison does not consist of, living germs. They contend that putrefaction, as stated, is propagated by contact with minute portions of putrid matter, which also is the mode of multiplication, and the form assumed by zymotic poison, whether it be expired from the lungs, exhaled from the skin, or ejected from the bowels. They, moreover, concede that each communicable disease has its specific poison, but deny that the poison causes disease by an inherent self-reproductive power. Zymosis, they consider, is continued from person to person by the virus imparting its condition to individuals, which contain in themselves that which is capable of being changed into the poison. Perhaps the most feasible enunciation of the physical theory is that of Dr. B. W. Richardson, of which the following are among the chief points:—"Zymotic poisons are organic products derived from the secreted fluids of the body, so that a zymotic patient is poisonous precisely as a cobra di capello is poisonous; he is secreting virus, which, by contact with a healthy person, may cause disease. As each secretion of the body in its healthy state has specific properties so each in its diseased state acts as a specific poison, and, from its local position when thus acting, peculiar local symptoms are set up characteristic of the disease. There is thus a different secretion forming a pabulum for each poison, one for small-pox, one for scarlatina, and so on, the one virus not thriving on the food of its neighbour, but electing its own secretion. This is said to explain why one poison does not produce the symptoms of another. According to the germ theory each zymotic case yields an enormous number of germs, all of which retain their vitality amid extreme temperatures, so that the wonder is the world is not depopulated with them. But the physical theory places zymotic virus under the same atmospheric influences as other organic matter, whereby it is soon reduced to elementary forms. Hence the dead are not contagious, and epidemics cease." Dr. Richardson also considers that zymotic poison may, under certain mal-hygienic conditions, arise, *de novo*, in the secretions, from which effects follow precisely as though it had been introduced into the body; and attributes the immunity from, or tendency to, zymotics at various ages to a constitutional or physiological peculiarity of secretion; and the non-recurrence of the same disease in the same person to the elimination of particles in a secretion susceptible of zymosis.

It seems to me strong proof in favour of the physico-chemical theory that certain epidemic distempers—sweating, sickness, plague, and black death, have ceased to be. It may be mentioned that during one night in London the plague caused 4000 deaths, and in one week 12,000. If these depended on germs, whither have the germs gone? and, moreover, where were the germs of cholera previous to its appearance on the Ganges' Delta? I think it more likely these diseases did not arise from germs at all, but from putrid poisons generated, *de novo*, both in and out of the body, but chiefly the former, from abounding decomposing organic matter, the deplorably filthy habits of the people, and their abject ignorance, and systematic violation of the laws of health, and were propagated also in accordance with the physical theory. Further, as their extinction is unquestionably due to increased knowledge and improved sanitary conditions, may it not, therefore, be reasonably expected to exterminate scarlatina, typhoid, and their allies, by the same means, as it seems to me highly probable they arise and disseminate in a similar manner.

But still we have to consider the important question, What is the specific nature of zymotic virus? Be it living germ, putrid particle, or vitiated secretion, if it be at all tangible, what does the microscope or test-tube say about it? Briefly, it must be admitted, that all the most refined and ingenious methods of research, as to the presence or properties of the mineral and vegetable poisons, physical, physiological, toxicological, or antagonistic, afford but a tantalizing, yet withal, encouraging glimmer of light, when applied even to reveal the presence, let alone unmask the specific *zymes* of zymotic virus. But most of the great discoveries of science, now shedding their benign rays over the whole earth, appeared at first like the phosphorescent scintillæ on the abdomen of the glow-worm under the hedge. So may this feeble glimmer, probed by constant experiment, and fanned by the breath of increasing knowledge, flame into radiant, far-reaching, and enduring shafts of intellectual light.

The proximate infecting principle of one of the most virulent of the zymotica, viz., the lymph of small-pox, is easily procured, and in sufficient quantity for examination. This substance, also cow-pock lymph, is fluid, translucent, odourless, alkaline, and coagulable. Under the microscope both are found to contain numerous particles about 1-20,000th of an inch in diameter. By an ingenious application of the law of diffusion of fluids, M. Chauveau and Dr. B. Sanderson managed to separate the particles from the fluid parts, and it was found that a child may be vaccinated or innoculated successively with the fluid, but without effect, while the minutest portion of the solid parts that can be separated is sufficient to originate all the phenomena of cow-pock, or of variola. Now the specific virus of the other zymotic diseases, such as scarlatina, typhoid fever, etc., has not yet, in reality, been isolated; but it may be safely predicated that if they too contain particles, these must be smaller than a blood-corpuscle, that is less than the 1-4,000th part of an inch, because if larger, or of equal size, they could not penetrate the membrane of the lung cells when inhaled, nor the vascular tunics when swallowed, to pass into the circulation, as what keeps the blood corpuscles in, must keep particles larger, or of equal size, out. But, supposing these contagia to consist of minute entities of putrid amorphous matter, then they need not be so small as a blood corpuscle, because mere contact with the pulmonary membrane, or any moist absorbing surface of a susceptible organism, would be sufficient, in accordance with the physical theory, to initiate zymotic phenomena conformable to the nature of the primary contagium.

At present it must be confessed, as already stated, that of what the infecting principles of zymotic contagia consist, no one knows! The discovery that the particles in vaccine and variolous lymph are the essential virus of these substances, is one of the golden grains of fact that has been washed out of the worthless sands of hypothesis, but as regards their particular constitution, again the sum of our knowledge is, no one knows! Furthermore, the splendid discovery of Jenner of the protective influence of vaccination has, as you know, enshrined his memory in imperishable characters on the escutcheon of science, and excited the wonder, admiration, and gratitude of the civilized world. But why the particles of vaccinia prevent the development or generation of the particles of variola, the sum of our knowledge again is, no one knows!

I cannot avoid mentioning here that previous to Jenner's discovery, nay, for some time after he had made it known, and while he worked on crystallizing his sublime idea, imbued with the true spirit of a philosopher, nathless for the drenching shower of epigrams, and lampoons, and caricatures of men with cows' heads, directed against it, in Europe alone, 400,000 persons were dying annually from small-pox, while the same number were disfigured from its effects. At present the mortality from this disease is approximatively only about a fifteenth part of what it was before the introduction of vaccination. It has been well said that he who disputes the benefits of vaccination is as unreasonable as he who opposes in like manner any proposition in Euclid.

Regarding the origin and phenomena of zymotic disease, a recent writer observes: "The more we reflect on the life history of contagion, the more puzzled we become; the more we reach after this subtle poison, the further it seems from our grasp; the more carefully we lay hold of one fact after another, the greater number of new facts spring up, mushroom-like, before us."

In conclusion, as your profession is closely allied with medicine, it is likely some of you may become medical practitioners. To those I would say, then you will frequently find yourselves wrestling in hopeless conflict with this terribly unequal antagonist. The learned, illiterate, rich, poor, young, old, it spares none of them. Then, often amidst the entreaties of children to save a parent, or parents, their children,

"Before zymosis' fevered fingers
Hath swept the lines where beauty lingers,"

you will realize how contemptible and impotent are all your powders and potions, and numerous devices to thwart, in the smallest degree, the fatal issues of these protean maladies; and baffled and beaten, wish in your inmost heart for another Jenner—a Jenner of the nineteenth century—who by some weird alchemy will charm and chase away for ever those dismal death's-head shadows that, with leperous wings distilling poison, are constantly swooping unseen and noiselessly upon us, darkening our homes and desolating our hearths, ruthlessly lacerating the tenderest ties of human sympathy, and cruelly strangling the fondest hopes of human love.

EXTRACT OF LITMUS.*

BY J. MARTENSON.

The colouring matter of litmus, when purified as much as possible, may be kept for an indefinite period unaltered in glycerin. Litmus is treated with hot water, and the solution, after concentration, is mixed with a sufficient quantity of alcohol (of 80 p. c.) to precipitate the colouring matter. After standing for twenty hours the alcohol is poured off, and carries with it a dirty blue foreign substance which frequently occurs in litmus, and is not altered by acids. The sediment is treated with hot water, which dissolves it on account of the potassium carbonate which is present. To remove this carbonate, sulphuric acid is added till the liquid assumes a faint wine-red tint; it is then heated to boiling for a few minutes, and again rendered blue by the addition of a few drops of lime water. After the lapse of twenty-four hours the liquid is filtered and evaporated to a syrup, and left all night in a cool place, when the potassium sulphate crystallizes out in the form of a crust. It is then filtered through moist cotton, mixed with glycerin, and carefully preserved from damp.

The Pharmaceutical Journal.

SATURDAY, JANUARY 9, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

LEAD IN LEMONADE.

SHOULD Mr. THOMS, who has devoted so much time and acumen to the task of proving centenarians to be mythical, ever fall short of evidence, he might take the ground that, according to modern discoveries, a man ought to be done to death by poison over and over again, long before he attains the age of one hundred years. In fact, the revelations of sanitary commissioners, and analytical commissioners, and public analysts, *et hoc genus omne,* are sufficient to make any man, who possesses only a moderate amount of assurance, ashamed of having lived the allotted three score years and ten. Surely, even the sons of the prophets had not more reason to call out "There is death in the pot!" than a nation of which 10,000,000 suffer annually from zymotic poisoning and 100,000 die; whose bread is made indigestible by alum; who swallow iron with their tea, cocculus indicus with their beer, copper with their pickles, and chalk with their scammony; who have their milk and babies' foods rendered useless by dilution, and their mustard poultices ineffective by flour; and who cannot even drink a bottle of lemonade or soda-water without swallowing a poisonous dose of lead.

We are far from undervaluing the work of those who during recent years have so usefully attracted the public attention to the public health; nor do we think that the sensational manner in which it has been sometimes done has been altogether without its uses. But as regards the pseudo-science which is with this object sometimes thrust upon the public, there is a danger of its influencing a wider sphere, and affecting the opinion of scientific men to the weakening of the public faith in their conclusions.

In this respect we have more than once seen with regret a tendency on the part of public analysts to allow popular beliefs so far to interfere with their judgment as to induce them to confuse facts with conjectures in their official evidence. Thus, for illustration, some time since a plausible demonstration before a magistrate led to an assumption of the presence of iron filings in tea; and the rut being once established, it was followed by analysts in their certificates until there was cause for wonder as to the possible source of all the filings. Then, in a case where analysts were more numerously represented than usual, there came the collapse, and it became pretty manifest that though iron was present, it was in another form that pointed to another continent as the source of the adulteration. It cannot be denied that damage was thus done to the reputation of public analysts which might have been avoided, while the adulteration would have been equally demonstrated had the certificates and evidence simply testified to the presence of iron in the tea.

An article in our columns this week taken in conjunction with a note published about two months since (p. 339), suggests a fear that a similar *faux pas* has been taken with respect to the origin of lead found in lemonade. A few months ago the public attention, which had been aroused by paragraphs respecting the action of water on leaden pipes, based on some communications to the French Academy, was further stimulated by certain excusable vauntings of the advantages of natural aërated waters over those artificially aërated. This was followed by the discovery that aërated waters containing injurious quantities of lead were actually being sold, and the public were informed that this lead was dissolved from the apparatus during the process of manufacture. Prosecutions under the Adulteration Act have followed, and we think it is to be regretted that the certificate of the known fact that lead had been found has been complicated by an equally strong assertion that it was derived from the apparatus. Of the three cases reported during the last fortnight, the admissions of the defendants in the two respecting soda water favour the probability of this assumption. But in the lemonade case (p. 515) there is a manifest difference. There the defendant asserted—and this was not denied—that he had caused all the lead to be removed from the apparatus, and replaced by block tin. Admitting the correctness of the analysis, he evidently disputed the correctness of the inference respecting its origin. We do not say that in this he was right; but it is curious that Mr. EKIN's communication points to the possibility of his being so. Mr. EKIN's discovery of the presence of lead in commercial citric acid confirms what had already been stated by Mr. REICHARDT, who also found it in citrate of magnesia. That the method of preparing citric acid allows of this contamination is evident. That it has not attracted more attention may be accounted for by the fact that pharmacists are supplied with an article supposed to answer the Pharmacopœia tests, which guard against the presence of lead. On the other hand, it may be that the maker of aërated waters has sought for a cheap rather than an absolutely pure article. It is obvious, however, that it behoves pharmacists not to take it for granted that the citric acid they receive is always free from lead.

Of course, whether lead in lemonade owes its origin to the leaden pipes of the apparatus, or to the citric acid used in its manufacture, it is equally an adulteration, rendering the seller or manufacturer liable to penalties under the Adulteration Act. But what we venture to suggest to public analysts is, that they should rest satisfied with this fact, and not risk injuring their position in the public esteem by unscientific speculations.

THE SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

USEFUL as a Conversation Room may be for many purposes, it is evident that the desultory talk uttered there, even if it be on educational topics, can have but a limited influence in the systematic acquirement of knowledge. It is therefore satisfactory to note, in the report of the Council Meeting on Wednesday last, evidence that the students at Bloomsbury Square are not disposed to "rest and be thankful" at this stage, and that they have confidence in the desire of the Council to assist them in every possible way in their studies. We understand that the "School of Pharmacy Students' Association," referred to on p. 554, has been formed to promote the study of chemistry, pharmacy, botany and allied branches of knowledge among the members, by the reading and discussion of papers, or verbal communications on these subjects, of an educational rather than original character, at weekly or fortnightly meetings in the Society's House during the session. A code of rules has been drawn up, in which it is provided that past and present students of the School may become members of the Association upon the payment of a small annual subscription. Provision for carrying on the Association from year to year is effected by making the President, who is also to be an officer of the School, a permanent officer; the other officers are to be elected annually. We also note that no alteration in the rules is to be made without the sanction of the Council of the Pharmaceutical Society. Professor ATTFIELD has kindly lent the weight of his name to the young Association by becoming its first President. The Secretary and Treasurer is Mr. JOHN MORRIS BROAD, Hornsey Rise, London, N., to whom communications from past and present students desirous of becoming members should be addressed.

A NEW VARIETY OF SENNA.

WE understand that there is now in London a very large quantity of a drug which is being offered as fine senna. It may be distinguished from officinal senna by the peculiar arrangement of the veins of the leaf. Instead of having one central vein, with all the others branching from it, as in senna, the leaves of this variety have two or more prominent veins starting from the centre of the base of the leaf, and these are repeatedly forked in an almost parallel manner. The leaves appear to belong to a species of *Cassia*, and may therefore possess purgative properties. We hope to be in a position to give further particulars respecting this drug in our next issue.

SPURIOUS CHIRATA.

THE admixture of other species of Chirata with the officinal plant has evidently been overlooked for some time, for in two samples in the museum of the Pharmaceutical Society, both of which have been in the collection for several years, the species detected and described by Professor BENTLEY is present to a considerable extent.

THE IDENTITY OF COLLOID ANIMAL MATTER.

IN a lecture on the Pathology of Pectous Changes, recently delivered by Dr. B. W. RICHARDSON, he expressed the opinion that all the variations of colloidal matter present in the body, and known under the different names of fibrin, gelatin, albumen, globulin, casein, and chondrin, are but modifications of one form, induced by combinations between it and water, through the medium of inorganic bases and salines having an affinity for water, which fix it in combination. The purest colloid, which by perfect dialysis is most completely freed from these intermediate substances, is the most easily converted from the soluble into the insoluble pectous form. Fibrin he considers to be, perhaps, the closest approach to the pure form of colloidal matter in the human body, the most free from any such fixing intermediate agent: hence the readiness with which it passes from the soluble into the coagulated or pectous condition.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, January 6, 1875.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Greenish, Hampson, Robbins, Savage, Sandford, Shaw, Stoddart, Sutton, and Williams.

The minutes of the previous meeting were read and confirmed.

A Member and an Associate of the Society before the year 1842, were restored to their former status upon payment respectively of the current year's subscription and a fine.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society:—

Cox, William Dennis ....Grantham.
Currie, Robert Kirkwood ......Glasgow.
Flint, Charles Bruce............ ..Glasgow.
Frazer, Samuel McCall............Glasgow.
Knight, Benjamin..................Great Torrington.
Newton, Thornton Albert Claughton...Clapham.
Shapley, Charles ....Torquay.
Stacey, Henry George ,...........London.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

Adams, William ....Barnstaple.
Cox, William Dennis ....Grantham.
Currie, Robert Kirkwood.........Glasgow.
Dale, John ....Birmingham.

Evans, Gwilym ....Llanelly.
Flint, Charles Bruce............ ...Glasgow.
Knight, Benjamin...................Great Torrington.
Newton, Thornton Albert Claughton...Clapham.
Shapley, Charles ....Torquay.

Chemists and Druggists.

Gibson, Frederick Turner ......Birmingham.
Lacey, Samuel ....North Brixton.
Pye, John ....Dartmouth.
Smith, Anthony.....................Hull.
Standring, John.....................Manchester.

Mr. Robert Elimelech Read, an Associate of the Society before 1842, was elected a Member of the Society.

ASSOCIATES.

The following, having passed their respective examinations, were elected "Associates in Business" of the Society:—

Minor.

Ballard, Frank Perry ....Wootton Bassett.
Buckle, James ....Malton.
Farrow, Charles Henry ....Islington.
Litchfield, John ....Longton.
Robinson, Joseph...................Stanley.
Smith, Alfred Lambert..... ....Birmingham.
Squire, Thomas ....London.
Westwood, Amos ....Brierley Hill.

MODIFIED.

Carman, John ....Holywell.
McIntosh, James ....Huntly.
Prentice, Charles William ......Portland.
Sutherland, Daniel Dunbar......Totnes.
Taylor, Thomas Charles ....Aylesbury.

The following having passed their respective examinations were elected "Associates" of the Society :—

MINOR.

Baker, John Hopper ....Bristol.
Carrington, Edward Green ....Bakewell.
Crossley, Newbold ....Bury.
Dale, George Edgar ....Colchester.
Davies, John..........................London.
Evans, Evan ....Cardiff.
Evans, Richard.......................London.
Horton, James Alfred ....Aberdeen.
Johnstone, William ....Nottingham.
Kennett, John Nash ....Havant.
Makinson, Thomas ....Hampstead.
Maxwell, James Ashworth ....Altrincham.
Moore, Joshua ....Preston.
Phillips, Frank Leslie ....Birmingham.
Pitchford, William ....Newton Abbot.
Price, Robert John ....Wrexham.
Pritchard, Owen ....Bangor.
Sandwith, William Henry ....Scarborough.
Shepherd, Alexander Moir ....Aberdeen.
Smith, Richard Henry.............Leeds.
Tocher, John... ....Aberdeen.
Wells, Ernest William ....East Dereham.
Wilson, Griffith Phillips ....Merthyr.
Woolnough, Harry Arnold ....Norwich.

MODIFIED.

Bell, Charles Christopher ......Nottingham.
Fields, Cotnam ....Birmingham.
Lewis, Thomas .... London.
Mount, James ....London.
Munn, Charles Henry ....Worcester.
Simpson, John ....Glasgow.
Williams, Thomas...................Chester.

APPRENTICES.

The following having passed the Preliminary Examination were elected "Apprentices or Students" of the Society: –

Adams, Charles.......................Birmingham.
Alcock, Henry .... Coventry.
Andrews, Henry Albert ....Harrogate.
Atkinson, John Thomas ....Boston.
Baker, George Henry ....Southsea.
Bell, Henry ....Newcastle-on-Tyne.
Broadbent, John ....Manchester.
Bunning, Henry .... London.
Carr, John Allen ....Lancaster.
Cocks, Walter James ....Southsea.
Crawley, John ....Wotton-under-Edge.
Crook, Arthur Williams ....Preston.
Elliott, William Alfred ....Bristol.
Fargher, Henry Spencer ....Warrington.
Fox, Frederick William ....Lincoln.
Furness, Joseph Machin ....Liverpool.
Glass, William ....Friockheim.
Gregory, Edward Thomas ......Fulham.
Hart, Arthur...........................London.
Hawthorne, Charles Oliver ......Stafford.
Highmoor, George Samuel ......Leeds.
Holmes, Philip .... Walham Green.
Horrell, Alfred Charles Julian...Dartford.
Ison, Francis...........................Penrith.
Jeffries, Benjamin....................Brixton.
Jenkins, Evan Walter............Lampeter.
Jones, Richard Edward.........London.
Jones, Thomas Mantle............Stafford.
King, John William................Bolton.
Knott, Henry Archer............Walthamstow.
Longstaff, William Luther......Sunderland.
Middlebrook, Joseph...............Sheffield.
Morris, Walter ....Farnworth.
Murray, William Henry ....Surbiton.
Mushens, Robert Heslop ....Sunderland.
McCounal, Allan ....Dudley.
Newton, Arthur James............Dudley.
Opie, Edward Augustus.........Plymouth.
Pain, Arthur...........................Bury St. Edmunds.
Parkinson, Thomas Edmund...Leeds.
Phillips, James Patt...............Bideford.
Pollitt, Joseph Moore.............Radcliffe.
Procter, John..........................Pocklington.
Robertson, James Hay............Long Melford.
Rogers, James Isaac...............North Shields.
Rogers, Oliver ....Upper Norwood.
Rossiter, Thomas Edward ......Tiverton.
Sanderson, Robert Turnbull......Glasgow.
Smith, Joseph ....Sneinton.
Spilsbury, James ....Stafford.
Stevens, James Jesse Williams...Strood.
Taylor, Frederick Gordon ......Bristol.
Taylor, Philip Neville ....Tipton.
Tipping, William Thomas ......London.
Troughton, Henry ....Lancaster.
Villar, Arthur ....Staplegrove.
Walkley, James Byron............Bollington.
Welford, Richard ....Blackburn.
Wells, Albert Charles .. ..Leamington.
Wilkinson, William Halse ......London.
Williams, David ....Pembroke Dock.
Williams, Edwin ....London.
Williams, John Henry.............London.
Williams, John Thomas C.......Dolgelly.
Windmill, William Henry ......Barking.
Wright, Edward Goddard ......Doncaster.

The name of Alfred George Annette, of 65, Charing Cross, London, S.W., was ordered to be restored to the Register of Chemists and Druggists.

FINANCE.

The report of this committee having been read, a discussion arose with reference to the financial position of the Society, more especially with reference to the future sources of income. No resolution, however, was brought forward, and the report and recommendation of the committee were unanimously adopted.

BENEVOLENT FUND.

The report of this committee recommended the following grants :--

£15 to the widow of a late member of the Society, at Devizes, having three children, and being in delicate health;

£5 to a chemist and druggist, carrying on business in a small village in Gloucestershire, embarrassed by the expenses attending the last illness and funeral of a relative who was dependent upon him, and who had also been a chemist and druggist ;

£10 to a registered chemist and druggist, formerly in business, but who had been for some time out of employment. Since the receipt of the petition, applicant had obtained a temporary situation as dispenser, but had to support his wife and four children in separate apartments.

Another application from the widow of a chemist was deferred for further consideration.

The above recommendations were unanimously adopted.

LIBRARY, MUSEUM, AND LABORATORY.

At the recent meeting of this committee the librarian reported that he had sent a list of the duplicate books in the library to the secretary of the North British Branch, who had returned a list of those not in the Edinburgh library, and the committee now recommended that copies of such books should be forwarded to Edinburgh. A copy of Pereira's Materia Medica, edited by Professors Bentley and Redwood, was recommended to be purchased for the library. The attendance in the library during the last month had, on an average during the day, been 15·6 ; evening, 7. The number of books circulated during the month had been 126 in London, 40 in the country. A donation had been received from the East India Museum, through Dr. Forbes Watson, of a report by Dr. M. C. Cooke, on the gums, resins, oleoresins, and resinous products, in the India museum, or produced in India.

In consequence of an arrangement made by the House Committee that the room adjoining the library should be opened for the use of the students at five o'clock, the committee had ordered that the library should not be closed from 5 to 7 o'clock p.m., as hitherto. The curator reported that the first two sheets of the catalogue of the museum had been revised by Mr. Daniel Hanbury and Professor Bentley, and were now ready for the press. Estimates had also been obtained for printing the same.

Professor ATTFIELD had reported that 60 students had entered the laboratories since the commencement of the session : 48 being now at work.

The following books had been presented to the library through Professor Attfield, by their author, Dr. Beale :—

'How to Work with the Microscope.'

'Protoplasm; or, Matter and Life.'

'Bioplasm.'

The report was received and adopted.

HOUSE.

This Committee having considered the question remitted to them of appropriating a room for the use of the students, now reported their opinion that there was no room in the house which could be placed at the service of the students during the entire day ; but that they had ordered that the committee room adjoining the library be opened in the evening from 5 to 10 ; and that all persons connected with the Society, and all persons having obtained leave to use the library, should have the privilege of using that room under the supervision of the librarian. This regulation was directed to come into force on Monday, December 14th.

Mr. SANDFORD asked if any use had been made of the room.

The SECRETARY said the room had been open for fourteen evenings ; the highest attendance had been 15 ; average 3·6. On five evenings no one had used the room, namely December 23rd, 29th, 30th, 31st, and January 1st.

Mr. SANDFORD thought this result very satisfactory.

The report was received and adopted.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A memorial was read from a number of the students stating that they had formed themselves into an association for promoting general and pharmaceutical education by reading and discussing educational papers at weekly or fortnightly meetings ; and asking the sanction and approval of the Council to their holding their meetings in the Society's house. A copy of the rules, with the names of the officers, was appended, Professor Attfield being the President.

Mr. HAMPSON thought every facility should be given to the students to form such an association if they conformed to the regulations made for the use of the room ; as to which the Secretary might communicate with them.

Mr. GREENISH said one thing appeared to him rather anomalous. They had just approved of the report of the House Committee, according to which all persons connected with the Society or entitled to use the library were to be admitted to the conversation room, but according to the rules of this Association the members only and their friends were to be admitted to the meetings of the proposed Association.

Mr. SANDFORD thought the present application should be considered as being quite distinct from their recent decision as to the Conversation room. The students wished to form a society to meet once a week or fortnight under these rules, which seemed very good, and it appeared to him it would be better if they met in the lecture room.

Mr. SUTTON said the Lecture room was by far the best place if there were papers to be read or experiments to be performed.

Mr. SANDFORD said it was proposed to include those who were or had been students at Bloomsbury Square, and he hoped it would bring together many men who had been students.

Mr. ROBBINS said there had been an association formed some years ago of a somewhat similar character, of which he had been a member, and it worked very successfully for some years under the presidency of Dr. Redwood. It used to meet in the Council room.

After some further conversation it was resolved—

"That the Council approve the proposition of the students to form a School of Pharmacy Students' Association, and request the House Committee to make such arrangements as may be necessary to provide for the meetings."

LAW AND PARLIAMENTARY.

This Committee had held a meeting with reference to the prosecution of a chemist and druggist by the Excise authorities for selling under the name of a "Morning Tonic" a spirituous compound. A memorial on the subject had been sent to the Commissioners of Inland Revenue, to which no answer had been returned. After some conversation had taken place with regard to the action which it might be necessary to take, the report was received and adopted.

THE LATE MR. DEANE.

The oil portrait of the late Mr. Henry Deane, painted by Mr. Wyburd for the subscribers, was exhibited in the Council room.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The third general meeting of the present session of the above Association was held at the museum and library, Queen's road, on Friday, the 18th December, at 8 p.m., when a lecture was delivered on :—

THE CHEMICAL REACTIONS OF IODINE, BROMINE, AND CHLORINE.

BY MR. LOUIS SIEBOLD.

Having briefly alluded to the sources and the manufacture of these elementary substances, Mr. Siebold gave a description of their chemical properties in general and their analytical reactions in particular. In reference to the solvent action of water upon iodine, he maintained that the solubility of the latter was partially, if not mainly, due to the formation of hydriodic acid which takes it up much more readily than pure water. Pure powdered iodine, when shaken with distilled water for a few minutes, yields a pale yellowish solution containing a mere trace of iodine, but also containing a minute quantity of HI, as can be shown by shaking it with successive portions of chloroform until the latter remains colourless, and then adding a little nitrous acid whereby the chloroform which settles down after shaking will appear distinctly pink. By the long-continued action of water upon iodine a brownish-coloured and much stronger solution is obtained, but there is also a proportional increase in the amount of HI. This formation of hydriodic acid is favoured by light and heat. An aqueous solution of iodine, when heated gently on a water bath for a short time, or when exposed to the action of light for several days, becomes colourless and acquires the power of dissolving more iodine.

After explaining the various tests employed for the detection and separation of iodides, bromides and chlorides, the lecturer referred to the conflicting statements occurring in chemical books as to the action of solution of ammonia on bromide of silver. He said it was well known that this compound is much less soluble in ammonia than chloride of silver ; but while some consider its solubility as so trifling as to justify them in classing it along with AgI, others deem it soluble enough to recommend ammonia for the separation of Ag Br and Ag Cl from AgI. According to Löwig (Gmelin's chemistry), bromide of silver is soluble in strong but insoluble in weak solution of ammonia ; and others, again, consider it as partially but never completely soluble. His (the lecturer's) own experiments show that Ag Br is decidedly and perfectly soluble even in weak solutions of NH_3, but that it dissolves more slowly and requires a larger quantity of the solvent than the chloride. When dried and ignited Ag Br is very much less soluble in ammonia than the moist precipitate, but the same was the case with the chloride. A solution of Ag Cl in NH_4HO takes up Ag Br with much more difficulty than pure NH_4HO, so that a mixture of Ag Cl and AgBr is only completely dissolved by a large quantity of liquor ammonia. But, using such a large quantity, the separation of these two compounds from AgI always succeeds, whilst any attempt of separating AgBr and AgI from AgCl by ammonia would necessarily fail.

Having next shown how readily iodine may be detected in the presence of bromine and chlorine, or bromine in the presence of iodine and chlorine, and also chlorine in the presence of iodine, Mr. Siebold stated that the detection of chlorine in the presence of bromine was not so easy and could hitherto be accomplished only by Rose's test with bichromate of potassium and sulphuric acid. This test involves the trouble of a distillation, and requires care and the use of perfectly anhydrous materials. In the hands of inexperienced analysts it often fails to show traces of chlorine in presence of large quantities of bromine. He had now the honour of introducing to the meeting a new test which he thought would be found exact and practically useful. This test was based upon the fact that a strong solution of permanganate of potassium liberates the bromine from moderately strong solutions of bromides containing a large excess of H_2SO_4. It may be performed in the following manner:—A strong solution of $KMnO_4$ is added to the aqueous solution of KBr or NaBr (containing not less than 1 in 40), strongly acidified by dilute H_2SO_4, until the permanganate ceases to be decolourized, and a copious precipitate of MnO_2 is formed. The mixture is boiled for about five minutes to expel the bromine, and then filtered. The colourless filtrate is now quite free from bromine, and may be tested for Cl by $AgNO_3$. If a chloride be present, a small quantity of its chlorine is lost by this process ; but the main portion always remains, provided that no undue excess of $KMnO_4$ be used. It is essential therefore that the filtrate should be colourless, for if it be coloured so as to indicate the presence of undecomposed permanganate, the loss of the greater part, if not of the whole of the chlorine must be expected. If, on the other hand, too little $KMnO_4$ be used, a trace of bromide may be left in the filtrate. Instead of removing the MnO_2 by filtration, the boiled mixture may be rendered clear by the addition of $FeSO_4$; but filtration appears preferable to this process. If the solution under examination should be very much stronger than 1 in 40, water should be added before boiling (just after the addition of the permanganate), in order to avoid a loss of HCl.

By means of this test chloride may be detected even in the purest commercial samples of bromide of potassium. A bromide which is absolutely free from chloride, when treated in the above manner, yields a filtrate which forms no precipitate whatever with $AgNO_3$. Whether KBr contains a mere trace or a larger quantity of chloride, may of course be judged from the quantity of the precipitated AgCl. Alluding to the detection of Cl in KBr by means of a standard solution of $AgNO_3$, the lecturer thought that, for the detection of such an impurity, a good qualitative test would always be more reliable than a quantitative analysis. He stated that for want of a simple test, chemists rarely examined the bromide of potassium they bought, though the great medicinal importance of this salt rendered such an examination very desirable, the more so as large quantities of chloride were occasionally met with in samples of this preparation. As commercial bromine always contains a little chlorine, traces of KCl would occur in the best KBr, and could only be completely removed by an expensive process, or by a great sacrifice of material. He did not look upon small traces of chloride as an objectionable impurity.

Mr. Siebold also mentioned another new method of separating bromine from chlorine which he had but very recently discovered, but which, he said, required further experimental research to complete.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture I.

The History of Alcohol in Relation to some of its varied Services to Mankind in the Arts and in Science.

In commencing this course of lectures, the lecturer referred to the fact that within a few weeks an Archbishop and a Minister of the Crown had spoken respecting the part played by alcohol in the national history, the one dealing with its influence on the morals, the other with its influence on finance.

The lecturer considered there was yet scope for honest utterance on another side of the Alcohol question, and that to the moral view of the question and to the legislative might well be added the physical, and to this he proposed to direct public attention in these discourses.

The strain running through all these lectures, in however diverse a manner the subject matter of them may be pursued, would be simply this. Of what physical value has alcohol been to man; of what value is it to man? We know it is of no value to any other animal, and thus we limit our inquiry at once to the highest order of the animate series of natural development, or of natural creation.

He proposed to glance first at the value of alcohol to man in a general sense; that is to say to its value as an agent useful for other purposes than as a fluid to be imbibed. From this he would be naturally led to consider its action, physically, on man, and its use as a fluid consumed with, and, according to common acceptation, as a food. Lastly, he would treat upon its secondary action on the vital functions, physical and mental, *i.e.*, on the deteriorations of structure and function, which may follows its use. Dr. Richardson then proceeded with his lecture as follows:—

The Term "Alcohol."—The first employment of the word alcohol is obscurely recorded. Bartholomew Parr, one of the most learned of our scientific classics, taking the usual derivation of the word as from the Arabic *A'l-ka-hol*, a subtle essence, says it was originally employed to designate an impalpable powder, used by the Eastern women to tinge the hair and the margins of the eyelids. As this powder, viz., an ore of lead, was impalpable, the same name was given to other subtle powders, and then to spirit of wine exalted to its highest purity and perfection.

The earliest systematic and truly scientific use of the term that I can discover is in Nicholas Lemert's "Course of Chemistry," published in 1698. There the word is used as a verb, "to alcoholize," and the definition of this is said to be "to reduce to alcohol, as when a mixture is beaten into an impalpable powder." The word, says Lemert, is also used to express a very fine spirit; "thus the spirit of wine well rectified is called the alcohol of wine."

The word employed in this sense merely tells us of a refined fluid substance obtained by a subtle process of separation from a grosser substance. But it was not applied to the special fluid now under our consideration until long after that fluid had actually been separated. Then is was used as a supplementary term to the earlier terms, *Vinum adustum*, *Vinum ardens*, *Spiritus vini*, *Spiritus ardens*, by which a spirit obtained from the grosser fluid, by the action of fire, was known and described.

Fermentation and Wine.—We must now go back to a much earlier study, viz., to the study of the primitive fluid, from which the subtle spirit was derived. In the history of the production of alcohol we gather, in fact, the use of two of the most prominent words of our modern language: fermentation and distillation. They each mark distinct progressive epochs in natural science.

The term fermentation brings us in contact with the primitive fluid. It leads us to ask how, from the vegetable world, by change or mutation of its matter, a new product was evolved? The origin of this procedure is so old we have no possible means of tracing it. Before ever the word chemistry or the science which that word implies was dreamed of, this process of obtaining the crude liquor, from which alcohol was ultimately extracted, was in active operation. By some accidental discovery it had been started by human hands, and the act of first lighting and reproducing fire was hardly a less wonderful development of the higher faculties resident in man, than was this discovery. The operation itself, orginally, was, we may presume, very simple. As there is a spontaneity in nature to produce fire, as for instance, when a metal like iron strikes a stone, so there is a spontaneity of fermentation in vegetable matter — especially in the juices of fresh ripe fruits in warm weather — which fact being observed first, from the motion induced in the fluids, and secondly from the crude products that were left, would lead naturally to the contemplation of the steps of the process, to its easy, artificial, and more perfect development, to a method of separating and purifying the products, and afterwards tasting and using them.

The products of fermenting fruits were limited to four: an active air which escapes freely; a froth or yeast which floats above as a crust; a heavy mass or lees which sinks to the bottom; and a fluid which remains apart. These portions, each readily separable, indeed, separable of themselves, were soon understood in respect of their virtues. That invisible air, which escapes so

* Cantor Lectures: delivered during December, 1874, January, 1875, from the *Journal of the Society of Arts*.

actively, is a deadly vapour or miasm; that froth, unpleasant to the taste, is an active promoter of the motion that springs from the fruit; those lees are like sediment from muddy water, excrementitious, to be cast away; but that remaining subtle fluid, to the palate so grateful, to the senses so exhilarating, to the heart so forcing, to the intellect so exciting or so deadening—let it be brought froth in the daintiest cups the handicrafts can fashion from the rude earth! It is not, to the savage, a mortal thing at all. Water flows in open streams, a common liquid, at which cattle and creeping things may drink; this must be the drink of the superior intelligences from whom the savage came! It lifts the man who takes it into a higher sphere of life, or it degrades him to the lowest. It introduces him, as it were, to a new human organisation that is not to be a passing phenomenon, but, for good or for evil, is to remain for ages.

The fluid is wine.

The discovery is an epoch surpassed by none other in the history of one portion of mankind, and the early dawning civilizations show their wonder at it in their mythology. Egypt claims the invention for her god Osiris, Greece for Bacchus, and Rome for Saturn. The Greeks, most ambitious to be connected with the origin, assert that the very name belongs to them, for the drink was first discovered in Ætolia by Orestheus, the son of Deucalion, whose grandson, Oeneus, was so called from Oinos, which was the old name of the vine. Or else the discovery was by Oeneus himself, who first pressed the rich grapes. Thus Oinos—oinon—vinum—wine. Then by these nations the praises of wine and of the wine gods, one and all, were sung into the later times. The first of the Roman poets, excited to his labour by Mæcenas, the friend of Augustus, who would that the vineyards should flourish, is thus prompted to invoke Bacchus, under the name of Pater Lenæus—

> "Hither, oh, Lenæus—Father Lenæus, come.
> By thee with heavy viny harvest crowned,
> The pasture flourishes. In the full vats
> The vintage foams.
> Hither Lenæus, Father Lenæus, come,
> And, with thy buskins off, in the new wine,
> Stain, thou, thy naked legs even with me."

And thus on until our own era, in which,—alas for the mutability of even god-like virtues!—under the title of "The Worship of Bacchus," our veteran artist, George Cruikshank, has turned the praises of his brother artist, Virgil, into scorn, and has transformed Pater Lenæus, the wine giver, into the destroyer of every civilization over which he has become enthroned.

It is worthy here of special remark that the invention of wine was local on the planet and that it came from some centre of the ancient world lying near to those points from whence our modern civilization took its rise. For when that civilization concentrated itself into bands, or armies, or navies, for the purposes of discovering new portions of the earth, where other savage nations, as they are called, dwell, it found the wine god, the wine cup, and the wine equally unknown. A good three-quarters of the old world knew no more of wine than of the people who invented it, until they were taught to know it—then they learned about it fast enough.

The practice of exciting fermentation and of obtaining the coveted fermented liquor once known, the knowledge was extended, until from varied vegetable substances wine became a product extracted by an art that was successful, however rude. The discovery of the ferment, that is to say, of the body that would produce fermentation, was sufficient to set in mutation or intestine motion a whole series of fermentable vegetable substances, and to extend the manufacture of various vinous fluids to an unlimited degree. From the expressed juice of the grape the transition was easy to other juicy fruits, such as the mulberry, the apple, the pear, the peach; from these again to those juices which exude from trees, as from the eastern palmtree; and from these again to such similar looking substances as manna and honey. From fruits, moreover, it was an easy transition to seeds, and from seeds that were soft and succulent to seeds that were hard and of the character of what we now call grain.

From all these varied sources of fermentable substances there was produced for ages the fluid containing the basis of alcohol. Its most common name was wine, though the term was modified by adjective additions signifying sometimes its colour, sometimes the place where it was made or marketed. Thus were introduced the white and red wines, the Vino Tinto and the golden unctuous Vino Greco. Even after the discovery (of which I shall soon again speak) of the existence of a distinct essence or spirit in wine, the original fluid held pre-eminence over all other strong drinks, and in the early and middle stages of civilization in Europe the number of wines that were used exceeded anything we now have in common use. Here is a list of ancient Roman wines in illustration of this fact. The wines are arranged in nine groups:—

Ancient Roman Wines.

1
Falernum
Massicum
Calenum
Cœcubum
Albanum
Setinum
Surrentinum

2
Chium
Lesbium
Leucadium
Naxium
Mamertinum
Thasium
Mœnium
Mareoticum

3
Album
Nigrum
Rubrum

4
Vetus
Novum
Recens
Hornum
Trimum
Molle
Lene
Vetustate edentulum
Asperum
Merum
Fortius

5
Coum
Rhodium
Myndian
Halicarnassum

6
Cnidum
Adrium

7
Mustum
Protropum
Mulsum
Sapa
Defrutum
Carenum

8
Passum
Passum creticum

9
Murrhina

This list by no means exhausts the names of wines of ancient date, but it is a sufficient indication of the extent of the "wine trade," if I may say so, long before our State Minister's invested capital reached its 117,000,000 of wealth. As a matter of some historical interest, it is worth a moment or two to touch on the special qualities of a few of these vinous drinks.

The wines of the first group were home wines. The Falernian was, it is believed, something like our modern Madeira, and was not commonly used until it was ten years old. After it was twenty years old it affected the body unfavourably, causing headache. This was the experience of Galen.

The wines of the second group were foreign. The Chian, also called the Ariusian, was in three varieties—austere, sweet, and intermediate; the Lesbian was considered diuretic.

The wines of the third group were named after their colour—white, dark, and red. The white were thought to be the thinnest and least heating; the dark coloured and sweet the most nourishing; the red the most heating.

Group four is named after qualities, of age, and the like: as old (Novum); new (Vetus); of the present year (Hornum); of three years (Trimum); mellow (Molle, Lene, Vetustate edentulum); rough (Asperum); pure (Merum); strong (Fortius).

The wines of the fifth group, marked Myndian, Halicarnassian, Rhodian, and Coan, were made with salt water. They were considered not to be intoxicating, but to promote digestion.

The two wines of the sixth group, viz., Cnidian and Adrian, were also medicinal wines. The first, it was believed, engendered blood, and was at the same time a laxative; the second was diaphoretic.

Of those of the seventh group, the Mustum was wine newly made, or the fresh juice of the grape. The Protropum was the juice which runs from the grapes without pressing. The Mulsum was a mixture of wine and honey. The Sapa was Mustum boiled down to a third. The Defrutum was the same reduced to half, and the Carenum was the same reduced to a third.

Of the eighth group, the Passum was a sweet wine, prepared from grapes that had been dried in the sun. The Passum creticum, also a sweet wine, is believed to have been the same as the wine which our forefathers called Malmsey; the veritable wine in which the Duke of Clarence, brother of Edward the Fourth, elected to be drowned.

The wine called Murrhina, placed in the last group, has a curious history. The Greeks had a wine of this kind, which consisted of a pure wine performed with odorous substances. The Romans had a wine similarly named, which is supposed to have been wine mingled with myrrh. It was administered to those who were about to suffer torture, in order to intoxicate them and to remove the sense of suffering.

The ancient wines retained their place probably until the end of the middle ages, but we have no reliable evidence bearing upon this point, if we except an occasional reference by some poet or physician to the subject of wine. Very slowly the names, rather than the wines, changed generally. The Roman conqueror who built his villa on our islands, and fitted it with so much taste and means of luxury, added to it his wine-cellar, in the manner he had been instructed by his forefathers, and from it took out his red and white and old wine, as we do now; boasting possibly of the vintage from which it was grown, and eloquent as to its age and perfect ripeness. If he had no old port, he had old Falernian or Passum; his rough and his sweet, his light and his heavy wines, the same as ~~our~~ connoisseur of to-day; except, perhaps, that he knew a great deal more in the way of fact about the vintages than his modern follower.

How the wines changed in name through the centuries will be gathered from the lists of the wines of Europe in use in the last century, collected by the distinguished chemist Neumann, and here subjoined:—

WINES OF ITALY.

Vesuvius.

Vino Greco
Mangiaguerra
Verracia
Vino Vergine

Tuscany.

Florence (white and red)
Monte Pulciano
Montalreo
Porte Hercole

Lombardy.

Modenese

Some of the wines here enumerated derive additional names from peculiarities in themselves. Sec, from which we derive the name of the wine Sack, on which Sir John Falstaff so keenly enjoyed himself, means dry; the wine being made from half-dried grapes. Malmsey was called by the Italians, "Manna alla bocca e balsamo al cervello," "Manna to the mouth and balsam to the brain."

From the same chemist of last century, who has collected for us such a long list of wines, we are supplied with a very instructive table of analyses showing the strength of spirit present in the different specimens. The wines analysed are tabulated in alphabetical order. I believe this to be the first true chemical analysis that was ever made, on an extensive and comparative scale of different wines:—

TABLE OF THE CONTENTS OF DIFFERENT WINES IN A QUART OF EACH.

	Highly Rectified Spirit.			Thick Unctuous Resinous Matter.			Gummy and Tartareous Matter.			Water.

If these analyses include all the spirit in the wines named, it is clear that the amount of spirit in them was exceedingly small, when compared with what is present in the wines of the present day. Falstaff might readily drink a pint of sack at a draught that contained rather less than seven and a half per cent. of spirit.

The only other diluted rival of wine obtained by fermentation was the liquid derived from corn. Tradition, active again in giving celestial origin to strong drinks, has assigned the introduction of the art of making this product first to Osiris, the divinity of Egypt, and afterwards to the goddess Ceres. The fluid thus produced, became, in Saxon language, known as beer, bere, from barley, or perhaps from the Hebrew, *bar*, corn. Tacitus calls it Zythum. The Egyptians, it is said, made it first for the common folk that they too might receive the gift of Osiris. In its original state beer was what we would now call the sweet fluid or wort fresh from the vat, and untinctured with any additional substance. So it continued probably until the ninth century, when it began to be treated with the *lupulus*, or hop. The first mention of this plant is made by an Arabian, named Mesue, of about the year 850, but he does not refer to it in relation to beer. The hop not only flavoured but tended to preserve the beer, and in a few centuries it became of general use. In the reign of Henry the Sixth the use of hops was for a time forbidden, on the ground that they spoiled the beer and rendered it dangerous. An order prohibiting hops and sulphur for beer was also made in the reign of Henry the Eighth. But the hops at last won their way. It is worthy of notice that Neumann, who analysed the beers of last century, as well as the wines, found that the beers contained an amount of spirit varying from 5 per cent. in the weakest to 10·90 per cent. in the strongest kinds. The malt liquors of the last century were, it appears from this, of much the same strength as those of the present.

Thus in the history of alcohol the first step of discovery was that of its production from vegetable matter by the process of fermentation. As so produced it was a mixture of that which we now call pure spirit, or alcohol, with water, and with small quantities of other extraneous substances of minor moment.

On the nature of the fermentative change by which the juice of the fruit, or the exuded fluid of the plant or tree, or the seed or the sweet sugar, is transformed into the new product, speculation has been rife for a hundred years at least. In this day the atomic constitution of water, of alcohol, and of the substances which yield alcohol are known, and the atomic change of constitution that takes place is known; but the reason of the process is, according to my judgment, as little understood as it was when the discussion began. Probably, indeed, the latest theories that have been advanced are rather a retrogression, by a line of learned subtleties from the earlier views, than an approach to simplicity of truth. I do not, therefore, venture to trouble you with any description on this head. One word I would add in the way of a guard against misuse of terms from assumed analogies. We often hear processes described as fermentative, which in truth have no relation, by any proved physical argument, with the true process of fermentation of vegetable matter connected with the production of wine. To take one example; we speak commonly of the zymotic or fermentative diseases, applying the term to those maladies which, in the form of contagious fevers, become epidemic. Hence many are led to believe that in these diseases there is in the body an actual fermentation like that in wine or beer; a comparison no closer, according to our knowledge as it now actually exists, than might be instituted between the same process and the so-called ferment of a mob when it assembles to give vent to its turbulent rage.

(*To be continued.*)

Parliamentary and Law Proceedings.

Supposed Poisoning by Corrosive Sublimate.

On Monday, January 4, an inquest was held at St. Thomas's Hospital, before Mr. Holl, coroner, touching the death of Celine Marin, a young Frenchwoman, who came to her death under the following circumstances:

Julien Robarts, servant at an hotel and restaurant, 35, Rathbone-place, who gave his evidence in French, which was interpreted by M. Albert, stated that the deceased, who lived with him as his wife, was a servant in the same house. On Sunday, the 13th December, the deceased, who was suffering from diarrhœa, asked him to go out and fetch her some bismuth. He went to a chemist's shop opposite and rang the bell, and a lady came and he asked for some bismuth, and told her it was for his wife, who was ill of diarrhœa, and that she had been recommended by a physician to take bismuth. The lady gave him one or two spoonsful of a white powder, without directions. He went back to the hotel and gave it to his wife, who said she knew how to take it, as she had taken some before. Five or ten minutes afterwards he found her on the stairs by the closet, and she said the medicine burned her very much. Another person came up and told him to give her some milk, and he did so, and she drank a large quantity of it, and he went over to the chemist's to see what the lady had given him, as the medicine had such an effect. He rang the bell several times, but no one came, and he went for Dr. Roupell, who came immediately, and he advised him to continue giving milk constantly, whilst he would go to another chemist's to see what the powder was, and procure an antidote. The deceased had taken it all, but a little remained round the glass, and he took it to another chemist's. The next morning he went again to the chemist's in Rathbone-place, and asked the woman whether it was bismuth she had given him, and she said "Yes;" and she gave some in a paper to the assistant of Dr. Roupell, who accompanied him. On the same day the woman came to see the deceased with a doctor, and she said it was an unfortunate affair, that it was an accident, but she could do nothing more, as her husband had made many mistakes on similar occasions, and that nothing was done to him. The deceased had not been taking any medicine previously.

Dr. Francis Roupell, 27, Charlotte-street, Fitzroy-square, stated that on Sunday afternoon, the 13th December, at half-past three, he was called by the last witness to see his wife, who was ill. He went to his lodging, and found she retched very much; she complained of great pain in the stomach, and was not able to swallow. She retched a little into a glass, which he took to Mr. Schomberg, a chemist. Being suspicious, he ordered an emetic, and on the same day he examined the contents of the glass, which seemed like a salt, but it was impossible to make a complete analysis of it then. The woman remained under his treatment for some days. Her tongue and her throat were swollen, and her mouth was full of saliva, from which he inferred she had taken some mineral poison. The whole inside of her mouth and throat was full of blotches. He administered chloride of potassium gargles, and beef tea. He attended her till she was taken to the hospital, which was done on his advice. It was his opinion that she had taken corrosive sublimate. He thought so from the symptoms and from the appearance after death. He did not analyse what was contained in the glass, but he tasted it, and was certain it was corrosive sublimate. Bismuth was the same colour, but the difference could easily be discerned by the touch.

Dr. Lingard, the house physician at St. Thomas's Hospital, said the deceased was brought to the hospital on Christmas Eve, and was taken to one of the wards. He attended her to the time of her death, which took place on the 28th. When she was brought in, some powder in a paper was given to Dr. Turner in his presence, and it was stated that she had taken some of it. He had tested it, and found that it was perchloride of mercury, a corrosive sublimate. He was present when a post-mortem examination of the body was made, and from the appearances it was evident that she had taken some corrosive poison, which caused death.

By the Coroner: Is there a difference in the appearance of corrosive sublimate and bismuth?—An experienced eye would detect the difference at once, but I do not think a woman would be likely to detect it.

Winnifred Kant then presented herself, and said she wished to be examined, and, after being cautioned by the Coroner that her evidence might be used against her, she stated that she lives at 15, Rathbone-place, which is a chemist's shop. She was placed there by the executors of the late owner simply to take care of the house, and she had nothing to do with the business carried on by Mr. Kerpinns, who was never there on Sunday. On the 13th December, which was on a Sunday, she heard a ring of the bell, and going to the door saw the last witness. He asked for sixpennyworth of rhubarb powder, and twopennyworth of bismuth. She gave him the six packets of rhubarb from the rhubarb drawer, and she gave him what she verily believed to be bismuth from the same place that she used to take it from for a gentleman who is now dead. Certainly the shop was shut; but she went to the same place, and took it from the same bottle. She afterwards went out, and remained out all the afternoon. She should not have given it him on any account whatever if she had not known the man. She saw "bi" on the bottle; but she did not stop as she should have done, and in her hurry she measured him some out in a spoon quickly. It was a very small spoon, and she gave it him nearly full.

Dr. Lingard said the spoon would contain sufficient to cause death.

Mr. Lewis Prosper Henry Beglim stated that he is Dr. Roupell's assistant. On the 14th December he went to the chemist's shop, 15, Rathbone-place. He saw the last witness, and asked what she had given the man Robarts the day before. She said he asked for bismuth, and she gave him bismuth. He asked to be shown the bismuth, and she took down a bottle containing a white powder. He saw it was not bismuth, although it was labelled bismuth. She gave him some, and he gave it to Dr. Turner, at the hospital. He told her it was poison, and she said, "I do not believe it is, because I know it is the same bottle I have served it from before." She also said it was a mistake, and that her Charley had done it before.

Winnifred Kant was recalled, and said she did not take the bottle down when the last witness called upon her. It was on the counter. It had not the word "bismuth" on it, but hydrobichloride. She said it could not possibly be poison, for it was the same as she had given the late Mr. Ungurer. He was in the habit of taking it. It was a white powder. She was so sure that it was all right that she took some herself, and she felt a little sick directly she took it on her tongue. She went to a physician and told him the case, and asked him to see the woman, and she went to the house, but they insulted her.

Did you say to Robarts that your husband had made many such mistakes?—No. I have not a husband. I never knew my late master make but one mistake, and that was when he gave me poison. I never served any one in the shop before, except with linseed or anything simple.

The Coroner, in summing up, said there was no doubt this woman died through having taken corrosive sublimate. By law persons were not allowed to sell poison unless they were properly qualified under the Pharmacy Act, but the woman Kant did not come under the Pharmacy Act, because she did not keep a shop in which poisons were sold.

The jury consulted for some minutes, and then said they wished to have more evidence as to whether the witness Kant had not been in the habit of serving in the shop.

The inquest was then adjourned for that purpose until Monday next.—*Daily News.*

Obituary.

Notice has been received of the death of the following:—

On the 20th December, 1874, Mr. Charles Tye, Chemist and Druggist, of Stonehouse, Gloucestershire.

On the 26th December, 1874, Mr. George Fentiman, Chemist and Druggist, of Upper East Smithfield, London. Mr. Fentiman had been a Member of the Pharmaceutical Society since 1869.

On the 27th December, 1874, Mr. Richard Smith, Chemist and Druggist, of Bridgnorth.

On the 12th August, 1874, Mr. J. A. Bullock, Chemist and Druggist, of South Shields. Mr. Bullock had passed the Minor examination about six weeks previously.

Correspondence.

ADDITIONAL NOTES ON JABORANDI, AND ITS PHYSIOLOGICAL ACTION.

BY WILLIAM MARTINDALE, F.C.S.

Having received, through Messrs. Hearon, Squire and Francis, a further supply of this remarkable drug, which has excited so much attention physiologically and therapeutically in Paris during the last twelve months, information respecting its previously doubtful botanical origin is now obtainable. In my former communication on Jaborandi,* I said I thought the statement of Professor Baillon that it was the leaf of *Pilocarpus pennatifolius* was erroneous, giving my reasons that having obtained some of the fresh leaves of *P. pennatifolius* from Kew Gardens, these differed so much in taste, odour, and more especially in physiological action from those of Jaborandi, that "Dr. Ringer and others, as well as myself, who watched the cases," in which both were used, "and examined the leaves and infusions of both, were satisfied this was not the same as the jaborandi we had tried before." I further stated that of course as these leaves of *P. pennatifolius* "were from a plant of hot-house growth, grown in its natural habitat its effects might be different." I notice lately that Professor Baillon still adheres to his statement.† Now that we have the whole leaf of Jaborandi to compare with herbarium specimens of *P. pennatifolius*, they undoubtedly greatly resemble each other. Still in our comparison with a specimen of *P. pennatifolius* at Kew, collected near Assumption, in Paraguay, Professor Oliver and Mr. Holmes noticed a difference in certain characters, and as jaborandi comes from Pernambuco, near to the Equator, whereas the Kew specimen was collected nearly 1000 miles further south, beyond the tropic which seems to be its general habitat, there is a great probability that they are not the same; if not the same, Jaborandi is a nearly allied, perhaps, as yet, undescribed species. This I leave for Mr. Holmes, who has taken the subject in hand, and will give a full botanical description of the parts of the plant that have been received, and other botanists, to decide.

In forwarding the supply the agents in Pernambuco wrote that "it is a medical shrub known by us, but little used, notwithstanding its excellent virtues, as the medical men here prefer using foreign medicines. It is an excellent sudorific in the dose of one octave to a cup of infusion. It is a good sialogogue. The tincture is used as a friction on paralysed members."

Of the importation lately received the leaflets form about one-fourth of its weight, the remainder being stems and leafstalks, with a few roots and fruit, but unfortunately no flowers. Compared with that which I first obtained from Paris, the leaflet of this is much more pungent in taste, and, I believe, for reasons given below, much more active physiologically. When chewed the taste is piquant, and excites a glowing heat on the tongue, like that caused by pellitory root. I also find from working with it that it irritates the skin when applied externally. On the inner surface of the bark of the root, white, shining crystals are distinctly visible; but as Dr. Attfield is about to make a chemical investigation of the different parts it is premature to offer any opinion about these. Therapeutically, Dr. Ringer is continuing his investigations at University College Hospital.

Having heard doubts expressed about the activity of the Jaborandi last received, as compared with the results obtained in the first trials I witnessed at University College Hospital, I became somewhat sceptical about its efficacy, and, therefore, expecting to get little results, tried it upon myself. To me the effect seemed simply marvellous. I made an infusion of sixty grains of the bruised leaf in five ounces of boiling water, let it stand fifteen minutes and strained it. On pouring the water upon the drug I noticed the characteristic odour almost entirely disappeared. The infusion was of a pale sherry colour, had a mawkish bitter taste, but did not excite the glowing heat upon the tongue that the leaf itself did; this I thought strange, and on tasting the dregs I found they still retained their pungent taste when chewed. It was evident to me that if its diaphoretic properties depended on the principle having this pungent taste, boiling water does not extract it. At 11·30 p.m., on retiring to rest, I swallowed as much of the dregs as I could, probably 50 out of the 60 grains used, and washed them down with the infusion. In five minutes I felt a glow, an increased circulation, an uneasiness in the head, became restless, and the secretion of saliva began to increase. At 11·45, a quarter of an hour after taking the dose, I was perspiring freely. The salivation and perspiration continued to be profuse until my sight became blurred. At a distance of four feet I could see my wife, but could not distinguish her eyes. On this occurring I became a little anxious, as I had evidently taken an overdose. I requested that Dr. Ringer might be sent for; he came about 12·15 a.m. The impaired vision still continued, but I was glad to find that it was only at a distance—near objects I could see distinctly enough. The pupils of the eyes were slightly dilated, I was informed. The pulse when first noted was 96, and got up to 104. The temperature was not taken. The depression was never very great, but a little before Dr. Ringer came I began to shiver, more clothes were put on the bed, and some spirit and water given to me. The excessive perspiration still continued from all parts of the body. A Turkish bath, which I have frequently had, and seen others have, was nothing to it; the saliva for a time required almost constant ejection; the secretion of this from the glands in the cheeks caused a kind of collapsed feeling in them. My speech was so affected that articulation was both difficult and indistinct. Eventually, about 1 a.m., I was sick, and vomited at first a quantity of saliva which I had swallowed. Putting my finger in my mouth vomiting was further excited, until a portion of the Jaborandi returned. The effects were now subsiding: more spirit and water were given to me, my night-shirt, soaked with perspiration, was changed. I was put into a warm blanket, and about 1·40 a.m. I fell asleep and slept a quiet sleep till 6 a.m. The pulse on awakening was 88—normally with me it is 80. I got up about 7·30 a.m., and although I felt squeamish all next day I was able to attend to business as usual. When the action was at its height, on uncovering my arm, I am informed the perspiration passed off in steam from my hand and night-shirt sleeve. The saliva collected, which was distinctly alkaline, measured 16 ounces, in addition to which a quantity had flowed on to the pillow while I slept, as it was quite

* *Pharmaceutical Journal*, 1874, p. 365.

† *Journal de Pharmacie et de Chimie*, Janvier, 1875, p. 23.

wet in the morning. I came to the conclusion that I should not like to pass through the ordeal again. My thanks are due to Dr. Ringer, whose presence and kindness greatly relieved my anxiety.

We have undoubtedly in Jaborandi a drug which produces a marked physiological action; how far it will prove useful therapeutically in cases of fever, diabetes, and other diseases, remains to be seen. A drachm dose of the last received is no doubt excessive, that is if the whole be swallowed. The strained infusion, from what I hear, produces but little effect.

M. Robin* gives an account of the results of his researches in M. Gubler's wards in Paris, but no mention is made of its peculiar action upon the vision, which, so far as I am aware, has not been previously noted.

10, *New Cavendish Street*,
January 12*th*, 1875.

CONTRIBUTION TO THE HISTORY OF KOSIN.†

BY F. A. FLUCKIGER AND E. BURI.

In Abyssinia, during a long period of time, the female flower-panicles of the Koso tree have been the most commonly used domestic remedy against tapeworm, for which purpose the handsome tree is cultivated in every village of that extensive mountainous country, recalling, according to Munzinger, in a measure, the lindens of German villages. The history of our acquaintance with this plant has been thoroughly set forth by Pereira,‡ though it is very questionable whether the oldest information quoted by him, of the year 1681, related to Koso. In the 'Historia Æthiopica,' of Sobi Ludolfi, otherwise called Lentholf, Frankfort, 1681, lib. i., cap. ix. (this curious folio is not paged), the passage runs thus: "Aliam arborem N. Godignus§ laudat contra ventris lumbricos valde proficuam; hos enim ex usu carnis crudi gigni: ut Habessinos singulis mesibus *fructu hujus arboris* alvum purgare, atque sic vermes illos necare memorat." Of course it is possible that by this "fruit" the seeds of the Koso tree were meant, which, acccording to Heuglin,|| are more active than the flowers.

The first exact description and representation of the tree were given in 1790, by the celebrated traveller, Bruce,¶ under the name *Banksia abyssinica*. The designation *Banksia*, however, had already, in 1781, been given by the younger Linnæus to a genus of Proteaceæ, so that *Hagenia abyssinica*, the systematic name chosen for the Kosso tree, in 1811, by Lamarck** is to be preferred.

In the Abyssinian dialects the tree bears different names; the shortly pronounced expression koso is preferred by Werner Munzinger†† as the most correct and most commonly used. Supported by the opinion of this famous writer, who is also an accomplished philologist, and is, perhaps, more intimately acquainted with the land and people of Abyssinia than any other scientific European, the substance to which these lines are devoted may be called "Kosin." Heuhlin, also (l.c.), writes "Koso."

It is much to be regretted that no experiments in the cultivation of the koso tree have yet been made in Europe.* It is highly probable that they would be successful, since the tree grows in the basins of the rivers Takazzi and Abai, at a level of from 3000 to 4000 metres above the sea, and similar habitats might easily be found in Southern Europe.

In 1840, Wittstein discovered in the Koso flowers an acrid resin, which Martin in the same year appears to have obtained in a crystalline form. In 1857, Harms attributed to it acid properties; in 1858, Paresi stated that he obtained it by means of alcohol and calcium hydrate.† The same method was employed by Dr. Bedall, of Munich, in 1862. From the aqueous residue of the alcoholic extract the koussin of Bedall, existing as a calcium compound, is precipitated by acetic acid as a more or less crystalline whitish powder, having the composition $C_{26}H_{44}O_5$.‡ Of this substance the flowers yield at the most 3 per cent. In 1867, Bedall attributed to it the anthelmintic action of the drug, and gave it a place in the materia medica.

Through the kindness of Herr E. Merck, in Darmstadt, we were put in possession of some beautifully crystallized kosin prepared by him. It was in the form of needles some millimetres in length, or of short thick prisms, which were well formed, but were not measurable, because their surfaces were too much furrowed. As the result of an optical examination, however, Professor Groth was able to determine that the crystals belonged to the rhombic system. If concentrated sulphuric acid at a temperature not exceeding 15° C. be saturated with kosin, the kosin is deposited, in the cold, in simple rhombic forms, or in stellate groups; most frequently, however, in twin crystals with interlacing angles. The specific gravity of kosin is so considerable that in sulphuric acid of sp. gr. 1·842 at 15°, it quickly sinks to the bottom. The colour of the crystalline needles agrees with that of sulphur; the larger prisms are of a somewhat darker yellow; while in the very fine ramifications,' the kosin appears to be white. It possesses neither smell nor taste, and when moistened with water or alcohol does not change litmus paper. Kosin bears being kept for a considerable time at 100° C., with as little loss of weight as over sulphuric acid or by fusing. Heated to 140° C. in narrow tubes, it begins to soften to and melt without decomposition at 142° C. After cooling, it remains perfectly transparent; but if this amorphous kosin be touched with only a single drop of alcohol there are immediately developed at numerous points tufts of radiating crystals, a process which has a very beautiful appearance, especially under the microscope, and which is repeated again and again in the smallest quantity of

this substance. This change of form is not produced by water.

Upon heating more strongly even a very small quantity of kosin, the odour of butyric acid becomes perceptible; at the same time, it forms a red brown tar, which in a very dilute solution of perchloride of iron gives rise to a brown colour. Heated in a current of carbonic acid gas, the kosin creeps to a considerable distance along the sides of the tube, but does not sublime.

Water boiled with kosin acquires a slight opalescence, without, however, any sensible quantity entering into solution. On the other hand it is very freely taken up by ether, benzol, carbon bisulphide, and chloroform; less freely by glacial acetic acid and alcohol. 1000 parts of the latter (sp. gr. ·818), at 12° C., is capable of dissolving 2·3 parts of kosin; but boiling alcohol dissolves it readily. By slowly cooling such a solution the kosin is obtained well crystallized, but not by evaporation. Crystals are equally well obtained from a hot saturated solution in glacial acetic acid upon cooling. The alcoholic or acetic mother liquor is subsequently rendered only slightly opalescent by water.

The solution of kosin in 20 parts of chloroform exercises no rotatory influence in a tube 25 millimetres long; while in a 50 millimetre tube the solution is not sufficiently transparent.

In two parts of concentrated sulphuric acid at 15° C. one part of kosin forms a yellowish solution wherein no change is produced by strong nitric acid. The solution quickly becomes of a clear yellow, and after longer standing in the cold a brownish and then a scarlet colour; the latter colour may be produced at once by warming gently, so that sulphurous acid is not developed. In this case especially the smell of butyric acid is developed. This is also the case when kosin is heated with nitric acid, sp. gr. 1·2. From the yellow solution kosin is precipitated as a whitish turbidity on the addition of water; but when the solution has become red by time or by heat, it deposits scarlet-coloured flocks.

Cold saturated alcoholic solution of kosin is at first scarcely altered by alcoholic solution of perchloride of iron, but after a short time it becomes a clear red. The same solution gradually acquires a similar colour in contact with reduced iron. The pure solutions also acquire a red colour on evaporation.

An alcoholic solution of neutral acetate of lead causes no precipitation from an alcoholic solution of kosin. Dissolved in chloroform kosin is not perceptibly changed by bromine.

Aqueous solutions of the caustic and carbonated alkalies—but not of borax—readily dissolve kosin, especially if gently heated; the yellow colour of these solutions also is changed to red by heating or long standing. Upon neutralizing these alkaline solutions there is formed, according to the temperature and concentration, sometimes a white amorphous, sometimes a pale yellowish microcrystalline precipitate, which, after perfect washing, is tasteless and without action upon test paper. It agglutinates when rapidly dried; but if first perfectly dried in the air at the ordinary temperature it does not lose weight at 100° C. In this respect the kosin precipitated from alkaline solutions, and that obtained from alcohol and chloroform, behave similarly. On the whole it would appear that the kosin precipitated from the alkaline solution is a return to the original form. The want of colour in the amorphous precipitate is dependent on the fineness of the particles, for their alcoholic solution yields again the former yellow crystals and white amorphous kosin, which, carefully dried, fused, and treated with alcohol, immediately yields beautiful yellow needles.

Heated in closed tubes with dilute sulphuric acid during a considerable time, kosin suffers no perceptible change.

If kosin be fused with caustic potash, and the mass dissolved in water, no precipitation takes place upon supersaturation with sulphuric acid; but the solution smells of formic and butyric acids, and contains oxalic acid.

The burning of kosin in a current of oxygen, which left scarcely a trace of ash in the platinum vessel, gave figures equal to the following percentages:—

	I.	II.	III.	IV.
C	65·06	64·92	64·25	64·23
H	6·73	6·81	6·61	6·52

From these results the formula $C_{31}H_{38}O_{10}$ is calculated, which requires:—

31 C	372	65·26
38 H	38	6·66
10 O	160	28·08

NEW CHEMICAL PROCESSES.*

BY J. PATTINSON.

For some time past, the chemical manufacturer, desirous of renewing or extending his plant has, as our cousins across the water say, "been much exercised in his mind," as to which, if any, of the new processes pressed upon his attention should be adopted. This perplexity is now gradually becoming removed by the knowledge gained of their value by actual practical working. In the manufacture of bleaching powder, for example, the rival claims of the Weldon and Deacon processes have long engaged attention. So far as can be seen at present, the conclusion arrived at appears to be one which, however unpleasant to the manufacturer anxious to economize his plant capital, ought to be very gratifying to the inventors of both these processes, namely, that it is advisable to have both methods at work. In the Deacon process in its present condition, there is a large proportion of the hydrochloric acid passed through the apparatus which escapes decomposition, but which is afterwards condensed and obtained as liquid hydrochloric acid. The best way to utilize this acid for the purpose of making bleaching powder is in the Weldon apparatus. The Weldon process, thanks to the chemical and engineering skill that has been brought to bear upon it, is a decided success; and Mr. Weldon claims that of the 100,000 tons of bleaching powder now made in this country annually, 60,000 tons are made by his process. It is in use in six of the manufactories on the Tyne at present, and others are having the plant erected. The acid from three to four tons of salt produces one ton of bleaching powder by this process. Not the least of its advantages are that it very much lessens the amount of polluting matter run into our rivers and sent into the air, and that it dispenses with one of the most disagreeable operations the workman has to perform in a chemical manufactory—the cleaning out and charging of the old chlorine stills.

The Deacon process is in operation in four of the manufactories in this district. The conditions necessary for the uniform and successful working of this process are not yet fully known. The produce of bleaching powder, for instance, from one decomposer varies as much as from 10 tons to 36 tons per week, and the cause of this variation

* From a Presidential Address delivered before the Newcastle-upon-Tyne Chemical Society.

remains to be discovered, excepting that it is known that irregularity of temperature has something to do with it. The greatest difficulty to contend with is, however, that of keeping the decomposer free from leakages and the consequent production of weak bleaching powder. The gases being drawn through the apparatus by means of a pump, any fissures in the decomposer cause carbonic acid to be drawn in from the surrounding flues and conveyed to the lime chambers. Still, in spite of these drawbacks, the usual yield of bleaching powder of good strength is about one ton for every two tons of salt decomposed, and this result is obtained when the pan acid alone is used. The cost for labour, fuel, etc., is very small. The process, therefore, even in its present state, may be said to be a very successful one, and when experience and research shall have more clearly indicated the conditions requisite for uniform working, it will probably become the chief process followed in our bleaching powder manufactories.

But little further is known of the process of making carbonate of soda directly from salt by what is called the "ammonia process." Messrs. Brunner and Mond carry it on at Northwich, but their operations, I understand, are kept so secret that nothing is known of them outside their works. Mr. Weldon, who has examined into the subject, expressed the opinion at a recent meeting of the Society of Arts that the process is so slow and the apparatus so expensive that it could not be economically worked. It may be of interest to some of our members to know that the direct ammonia process was experimented with in Gateshead about ten years ago. The trial soon came to an end, but from causes apart, I believe, from the success or non-success of the process.

The Hargreaves process of decomposing common salt is now making considerable progress. This plant is in operation in three manufactories in Lancashire, which at present are producing from 210 to 240 tons of sulphate of soda per week by its means. The Jarrow Chemical Company are also preparing to erect plant capable of making about 100 tons of sulphate of soda per week, and it is in process of erection in other works. For the information of such of our members as are unacquainted with this process, I may explain that instead of decomposing common salt by sulphuric acid as in the old process, Mr. Hargreaves uses sulphurous acid, air, and steam for this purpose. The salt, in a suitable mechanical condition, is placed in large cast-iron cylinders, ten to fifteen feet in diameter, and from ten to twelve feet high. A series of from six to ten of these are placed alongside each other and heated externally. Sulphurous acid direct from the pyrite kilns, together with air and steam, are passed through the salt in the first cylinder, then through that in the second, and so on through the whole series. A temperature of from 800 degrees to 1000 degrees Fahrenheit is found most favourable for the decomposition. It takes a fortnight or three weeks from the commencement of the operation to completely decompose the salt in the first cylinder; the salt in the other cylinders is, however, in various stages of conversion into sulphate at the same time, so that when the sulphate made in the first cylinder is drawn and the gas goes direct from the pyrites' kilns to the second cylinder, the salt in this becomes completely decomposed and ready for drawing one or two days afterwards; and so on with the other cylinders. The adoption of this process will work the most radical change in the chemical manufacturer's plant, for the old familiar large leaden chambers, and the decomposing pan and furnace, which have hitherto been indispensable, will then be superseded. As the cost of the Hargreaves plant is, I understand, much about the same as that which it will supersede for the production of a given amount of sulphate of soda, the superior economy of this process must be looked for in the saving of nitrate of soda, labour, and wear and tear.

I will now briefly call your attention to a few other new processes involving chemical operations, some of which have recently been introduced in this district, and others which are, I think, deserving of notice because they are likely to affect the interests of the manufactures which are carried on in our midst.

Of late years chemists and manufacturers have devoted much attention to the utilization of what have usually been considered waste products. The Weldon process already alluded to, in which peroxide of manganese is reproduced from the hitherto waste chloride of manganese liquors, is an instance of the success which has been achieved in this direction. This is also admirably illustrated in the treatment of the cupreous iron pyrites, now so largely imported from Spain and Portugal, by which almost every constituent of this mineral is now utilized and made a source of profit to the manufacturer. When the sulphuric acid maker has extracted the most of the sulphur, the burnt ore is handed over to the copper extractor, who not only separates the copper it contains, but, at the same time, so perfectly removes the remaining sulphur that the residue, consisting chiefly of peroxide of iron, is suitable for, and is now largely used in, various iron-making processes. It is well known that the original pyrites contain small quantities of silver—from half an ounce to one ounce per ton—and this is, also, now in many instances, separately extracted and sold. It is found that the most of the silver is obtained in solution along with the copper after the burnt pyrites has been roasted along with common salt and subsequent lixiviation with water. Mr. F. Claudet, a few years ago, patented a process for obtaining the silver from these solutions by precipitating it with an alkaline iodide, and this process is, I believe, successfully at work in some of the copper-extracting works in Lancashire. Within about the last twelve months, Mr. Thomas Gibb, of the St. Bede Metal and Chemical Works, has devised an ingenious method of extracting the silver from these solutions, which is now in successful practical operation at those works. Mr. Gibb's method of separation is based on the fact, I believe, first discovered by him, that when sulphuretted hydrogen diluted with common air is passed through a cupreous solution containing small quantities of silver, the silver is precipitated first, or, at any rate, that the most of the silver is precipitated as sulphide with a relatively small proportion of the copper. For the particulars given in the following description of this process I am indebted to Mr. Gibb. Sulphuretted hydrogen is generated by the action of dilute hydrochloric acid on soda waste, and drawn from the generating tanks, in admixture with common air, by a blowing engine which forces the mixture into the copper solutions. This is continued until about six per cent. of the copper in the liquors is precipitated, when it is found that the solutions which usually contain about 20 oz. of silver per ton of copper before the action of sulphuretted hydrogen, are reduced to 3 oz. of silver per ton of copper on the average, and the mixed sulphides of copper and silver precipitated contain about 200 oz. of silver per ton of copper. The sulphide precipitate is washed and calcined at a low temperature. The silver becomes soluble in common salt solution, the precipitate, although washed, retaining chlorides sufficient to change the sulphide of silver into chloride in the calcination. A part of the sulphide of copper is changed to sulphate, and the remainder to oxide, by the calcination. The sulphate of copper is washed out with water in wooden tubs, and the chloride of silver, with some chloride of copper, is subsequently dissolved out by strong hot brine. The sulphate of copper solution first washed out contains only about one ounce, and the oxide of copper remaining after dissolving out the chloride of silver 4 or 5 oz. of silver per ton of copper. The former is precipitated with the ordinary copper liquors in the usual manner, and the latter smelted with the ordinary copper precipitate. The solution of chlorides of silver and copper in common salt is mixed with milk of lime to decompose the metallic chlorides, and the chloride of calcium produced is washed from the precipitated oxides. These oxides are treated with dilute sulphuric acid, which dissolves the oxide of copper, leaving the silver. The residue, which contains about 10 per cent. of silver as chloride with sulphates of lime and lead, after the sulphate of copper has been washed from it, is dried and sold to silver smelters. Fully half an ounce of silver per ton of burnt ore is recovered, and although the operations just described appear somewhat numerous and troublesome, yet the total cost of recovery is not more than 1*s.* 6*d.* per oz. of silver. During this year, an amount of residue containing 16,000 oz. of silver has already been extracted at the Bede Metal Works by this process.

Another novelty introduced in our district, and which I think is deserving of the attention of our members, is the new form of condenser recently patented by Messrs. Newall and Bowman of the Washington Chemical Works, and which these gentlemen have in use and are now experimenting with for the condensation of hydrochloric acid in their works at Washington. In this condenser condensation is effected by passing the acid gas through one or more stone cisterns, about six feet square and two feet deep, into each of which water is entering through a small orifice of about 0·06 of an inch diameter, under a pressure of about 40 lbs. The fine stream of water is projected by this pressure with great force against a small disc, and is thus dashed into fine spray, which fills the whole of the vessel, and meeting with the hydrochloric acid gas, condenses it, forming liquid hydrochloric acid of the strength usually of 28 degrees of Twaddell's hydrometer. There is a considerable amount of heat developed by the condensation of the gas, and the vapour of water laden with hydrochloric acid after leaving the vessels in which the spray producers are placed is at present passed into a small condenser of the ordinary construction (much too small to do the whole work of condensation itself), where the vapour is cooled and perfectly condensed. In places where an ordinary condenser is not already in existence to be thus utilized it is proposed to place a series of cooling pipes between each spray producer vessel in order to cool the vapour.

It appears to me that these spray producers may be used with great advantage in washing and purifying the smoke and gases from copper works, outlets of sulphuric acid chambers, manure works, and in many other cases where noxious vapours are sent into the air. With such an apparatus the draught of the chimney need not be interfered with, and, what is of great importance for the effectual removal of condensable gases, every particle of the gases would be brought into contact with water. I would recommend that experiments in this direction should be made.

The spray producer may also probably be found of use in the purification of lighting gas as a substitute for the scrubber. An American engineer, Mr. B. E. Chollar, of St. Louis, patented, in 1872, an apparatus for this purpose, in which spray was produced by injecting water into a vessel through which the gas passed, by means of a jet of the gas under process of manufacture compressed to about 10 lbs. on the inch by a suitable compressor. More recently still, two French engineers, MM. Pelouze and Andouin, have patented a similar apparatus for the same purpose. Messrs. Newall and Bowman's water spray is, however, produced by much simpler means, and will probably be found to be as effective for this purpose.

A discovery has recently been made in iron metallurgy which is likely to be of very great importance to the iron manufacturers of this and all other districts where the iron produced contains considerable quantities of phosphorus. It has been considered an axiom amongst steel makers that it is impossible to produce good workable steel if the amount of phosphorus it contains exceeds somewhere about five-hundredths of a per cent. of the steel. As it is well known that neither the Bessemer process nor the Siemens-Martin process of steel making eliminate the phosphorus from the iron under treatment, it has hitherto been found necessary to use only such pig iron for these processes as were nearly quite free from this ingredient. The attention of chemists and metallurgists has therefore for long been directed to discover a method for effectually and economically removing phosphorus from its combination with pig iron, but hitherto no process better than the old puddling process has been devised, and this does not remove the phosphorus so thoroughly as to make the iron sufficiently free from it to fit it for the requirements of the steel maker. It has now been discovered that much more phosphorus may be left in the steel without injury to the product than has hitherto been thought possible, provided that the amount of carbon be at the same time reduced; in other words, the less carbon there remains the more phosphorus may be left in the steel. Thus a steel of good workable quality suitable for making rails is produced, which contains 0·30 of a per cent. of phosphorus, if only 0·15 per cent. of carbon be present at the same time. It is difficult to ascertain to whom the merit of this discovery is due. It appears that the late Mr. Matthiessen years ago held the principle upon which it is based, and Mr. Frederic J. Slade, of the New Jersey Steel Company, seems to have discovered the same principle and carried it into practice in the beginning of 1870. It has, however, recently been brought into public notice by the publication of the researches and experiments of M. Tessié du Motay and of M. Euverte of the Terre Noire Steel Works in France, and it was at these works that the steel of the composition just mentioned was produced. The chief credit of making the principle known, and showing how it can be carried into practice, may therefore be claimed by them. When the pig iron used in the Bessemer process has been decarbonized by the action of the air a certain amount of oxygen remains in the iron either as oxide or in some other condition, and it is necessary to remove this and, in this process as well as in the Siemens-Martin process, to add substances to convert the iron into steel. Spiegeleisen, a substance containing about ten per cent. of manganese and five per cent. of carbon, is at present used for this purpose. It is found, however, that when spiegeleisen of this quality is used in the necessary amount to convert the iron into steel it introduces too large a proportion of carbon to admit of a workable steel being produced from iron containing more than a few hundredths of a per cent. of phosphorus. When, therefore, "phosphorus steel," as it is called, is to be produced, it is necessary to use for the last-named process a material containing a smaller amount of carbon in relation to its manganese than spiegeleisen contains, and such a material is found in ferro-manganese, which can be obtained containing from 40 to 70 per cent. of metallic manganese and about 5 per cent. of carbon. This material is, however, very expensive, the present price being about 1s. 6d. per lb., and although only about two per cent. of it is required in the steel, yet this amount adds about £3 7s. 6d. per ton to the cost of the steel. At Terre Noire, however, they find that it answers their purpose to use this expensive material. No doubt means will soon be found to produce good ferro-manganese at much less cost. When this is the case, there is every reason to believe that Cleveland puddled bar may be largely used in the manufacture of steel. There is no difficulty in producing puddled bar from Cleveland pig iron containing only 0·2 or 0·3 per cent. of phosphorus, especially if the revolving puddling furnace is used, one form of which (Crampton's) promises now to be commercially successful.

At the present time there are several attempts being made to produce iron and steel directly from the ore without the intervention of the blast furnace. Besides the Siemens process, which was described by Mr. Siemens in a paper read before the Chemical Society in London in the beginning of last year, there are two or three being tried which are based on the principle employed many years ago by Clay, Renton, Chenot, and others, which consist in reducing the iron in the ore to the metallic state by heating it with carbonaceous matter in close retorts, and afterwards heating the reduced ore in reverberatory furnaces to melt out the slag and to weld the particles of iron together. The process of this kind which is attracting most attention at present is that of Mr. Blair, of Pittsburgh. He heats a mixture of iron ore and charcoal in vertical tubes forty feet in height and three feet in diameter. The upper part of this tube is heated externally by gas generated in gas producers, and internally by the combustion of the carbonic oxide arising from the action of the charcoal on the iron ore, whilst the lower part is cooled by encasing it in a water jacket. The iron which is reduced to the metallic state in the upper part of the tube is thus cooled down in an atmosphere of carbonic oxide in the lower part, so that when it reaches the bottom of the tube it may be removed in the air without fear of re-oxidation. The materials are fed in at the top and withdrawn at the bottom continuously. The metallic sponge thus produced is then pressed into lumps by hydraulic pressure and used for the making of steel in the Siemens-Martin process instead of wrought iron. The process has been at work for some time at the Glenwood Iron Works, Pittsburgh, and Mr. Blair claims that there is a very considerable saving in the cost of production of steel from his iron sponge as compared with the use of wrought iron. With very rich iron ores processes of this kind may probably be economical if a well-planned apparatus is used, but it is very doubtful if this would be the case with poor and siliceous ores, owing to the waste of iron which would occur in smelting out the earthy matters. Mr. Blair's process is not yet removed from the region of experiment, and the progress it makes will be watched with interest by all iron and steel makers.

RESEARCHES ON FOREIGN BITTER SUBSTANCES IN BEER.*

BY W. KUBICKI.

Professor Dragendorff, of Dorpat, has sought a method for detecting alkaloids, or other toxical and bitter substances which are introduced into beer. This method depends on the principle, determined by experiments, that, when the solution to be examined is agitated with petroleum, ether, benzine, and chloroform, the substances in question, when they have been used, are given up as well by the acid solutions as by those which are alkaline, when these solvents are evaporated so as to give a residue.

This method has been applied by Professor Dragendorff in the examination for the bitter substances usually employed, and also for substances which are not alkaloids, as picric acid, salicin, colocynthin, picrotoxin, and capsicin; also for the following alkaloids: strychnine, atropine, hyoscyamine, and the opium alkaloids sometimes used to falsify beer.

Mr. W. Kubicki has also, on his part, applied this method, and in a memoir inserted in the *Journal der Pharmacie für Russland*, August 1873, has given an account of his labours, of which, considering its length, we can only give an extract.

Mr. Kubicki's researches had for their object the detection of the following substances in beer by this method: *quassia cetraria* (quassia), *Absinthium* (absinthe), *Trifolium fibrinum* (Menyanthes trifoliata), *Ledum palustre* (marsh tea), *Cnicus benedictus* (blessed thistle), aloes, *Cetraria Islandica* (Iceland moss),† *Erythrea Centaurium* (red centaury), *Daphne Mezereum* (yarrow), *Gentiana* (gentian), and he has also extended his researches to the alkaloids of colocynth and the Levant wormseed.

First of all it was necessary to make certain of the reactions afforded by the pure extracts of malts and hops, as well as those of pure beer with and without hops. As it appears to be established that the fermentation has no effect, and that the addition of hops only affects the flavour, the experiments were all made on extracts, and preparations made expressly for the purpose.

In the examination of a hop beer, the author depended upon the works of Mr. Enders and Mr. Lermer, at least so far as they treated of the bitter principle of the hop. The latter was of but little use to him, because no reactions are given, and the crystalline form there described as characteristic, in consequence of the large quantity used by Mr. Lermer, and the vagueness of his method, could not be distinguished by the author.

The bitter principle of the hop is described by Mr. Enders as amorphous, easily soluble in alcohol, ether, chloroform, and slightly soluble in water. The aqueous solution is precipitated by plumbic subacetate, but not by tannic acid, ferric chloride, or mercuric chloride. It does not reduce an ammoniacal solution of argentic nitrate. It dissolves in concentrated sulphuric acid, turns brown, and precipitates in grey flocks when the solution is diluted.

The bitter principle obtained by Mr. Lermer has the following properties: It crystallizes in prisms, with a pure bitter flavour, hot and agreeable; it dissolves readily in alcohol, ether, chloroform, and in water to so slight an extent that it can scarcely be detected by the taste; but this flavour is strongly produced when the crystals are first dissolved in alcohol, and water is then added.

According to Mr. Leuchs, the hop bitter is decomposed by various substances, among others, by sulphurous acid and its salts, by aldehyde, and also by formic acid and its salts.

The researches of Mr. Kubicki on a pure beer as well as on a fermented and a non-fermented extract of malt, gave the following results:—

I. A. *In acid solution.*—Petroleum ether extracted but little; the residue from the evaporation of the solution, when separated, is small, amorphous, greyish-yellow; that from beer made with hops is a little more bitter than that without hops, with a taste and odour reminding one in general of amylic alcohol. Nitric and sulphuric acids give nothing characteristic.

The residue from the agitation with benzine is better characterized than the preceding; it is yellow, almost completely soluble in ether; that with hops is very bitter compared with that which contains no hops. Sulphuric acid, sulphurous, hydrochloric, sulphomolybdic (Frohde's reagent), and sulphonitric acids, bromine water, tannic acid, potash ley, potassio-mercurous iodide (Nessler's reagent), and tincture of iodine, are without very marked action upon it.

The residue from the action of chloroform is much more considerable than the preceding, dark yellow, with a slightly bitter taste, and almost the same for that made with or without hops. Concentrated sulphuric, sulphomolybdic, picric, and phosphomolybdic acids are indifferent to it. With tannic acid, the insoluble portion gives in ether a white precipitate, but none in the portion soluble in ether; the ammoniacal solution of silver is reduced, while that passing into solution in benzine does not give this effect. The author has therefore thought that two different bitter substances exist in the hop, of which the one dissolves in chloroform, and the other in benzine; the former possessing the properties remarked by Mr. Enders, while the other acts differently with the ammoniacal solution of silver and tannic acid.

B. *In alkaline solution.*—Petroleum ether extracted almost nothing; the other tests with the reagents were negative.

The residue from benzine was small, gray, a little more bitter with hops. Tincture of iodine, phosphomolybdic acid, and Nessler's reagent gave a slight turbidity, arising perhaps from the alkaloid discovered by Mr. Lermer

* *American Chemist* for November; from the *Technologiste*, No. 399, 1874.

† This substance has but little importance as a bitter, but as it gives a certain consistency to the beer, and makes it more frothy, it is often added to this beverage in the northern countries.

in beer. With regard to this alkaloid, Mr. Kubicki has found that it neither shares in nor interferes with the ordinary reactions serving to determine the identity of strychnine, atropine, daturine, or hyoscyamine.

The residue from agitation with chloroform is a little larger than that from benzine; is yellow, scarcely bitter, and afforded no reaction with picric and phosphomolybdic acids. All the residues, as well those from the acid as the alkaline solutions, were not crystalline. The substance obtained by chloroform in acid solution remained amorphous, even after treatment with ether or alcohol.

In reviewing the preceding facts, we see that, with the exception of the reduction of the ammoniacal silver solution by the acid product from agitation with chloroform, the precipitation of the portion from this product insoluble in ether by tannic acid, and the alkaloid reaction in the residue coming from the agitation with benzine in alkaline solution, the solutions from the agitation of malt or beer do not give any result which might cause error in the proximate analysis for other bitter substances than hops in beer.

II. The examination for bitter substances when mixed with beer, in pure aqueous extracts, was the object of the second portion of Mr. Kubicki's work. The quantities of these bitter substances cannot, in consequence of their flavour, be arbitrary; they must not give the beer a repulsive taste, or properties foreign to those of good ordinary beer. The examination should therefore only be carried to the detection of small quantities, and was undertaken in the following manner:—10 grammes of each substance, and 2 grammes of aloes were weighed out; some, as cassia, were boiled in two litres of spring-water, the others extracted by boiling water. The filtered liquor for each amounted to one litre.

Mr. Kubicki then proceeded to examine the reactions which characterized each of the bitter substances previously indicated, and to render the results obtained by Professor Dragendorff and himself more tangible, he has made up the following table:—

A.—Agitation in Acid Solution.

I. *Residue of Petroleum Ether.*

1. Crystalline, yellowish, slightly volatile. The solution remains yellow; potassic cyanide and caustic potash colour it red; on heating, cotton is dyed yellow. *Picric acid.*
2. Amorphous, white, sharp taste, and reddening the skin. *Capsicine.*

II. *Benzine Residue.*

1. Crystalline.
   - *a.* Not bitter, and becoming purple with caustic potassia. *Alvetine.*
   - *b.* Bitter, becoming yellow with caustic potash, and brown on heating. *Daphnine.*
2. Amorphous.
   - *a.* Sulphuric acid colours it brownish-red, tannic acid precipitates. *Quassine.*
   - *b.* Heated with dilute sulphuric acid, odour of menyanthole, with clouding of the solution, and elimination of oily drops. *Menyanthine.*
   - *c.* Sulphuric acid colours it blood-red, afterwards brown-red, hydrochloric acid greenish; after heating brown, cloudiness and elimination of oily drops. *Cnicine.*
   - *d.* Sulphuric acid colours it brown, afterwards blue-violet; same with sulphomolybdic acid. *Absinthine.*
   - *e.* Sulphuric acid colours it dark-red, sulphomolybdic acid fine cherry-red, tannic acid precipitates yellowish-white. *Colocynthine.*
   - *f.* Sulphuric acid colours it brown, hydrochloric greenish; on heating, the liquid turns brown and clouds. *Erythrocentaurine.*
   - *g.* Sulphuric acid colours it clear brown, caustic potassa yellow, brown on heating; tannic acid gives no precipitate, nitric acid of 1·42 colours red. *Gentian bitter?*

(Also sometimes a residue of *capsicine.*)

III. *Chloroform Residue.*

1. Crystalline.
   - *a.* Alkaline reaction none; sulphuric acid colours fine yellow; mixed with saltpetre ($NaNO_3$), then moistened with sulphuric acid, and finally, on adding a concentrated solution of soda, brick-red colouration. *Picrotoxine.*
   - *b.* Alkaline reaction. *Opium alkaloid.*
2. Amorphous.
   - *a.* No bitterness; caustic potash colours it purple-red. *Residue of aloetine.*
   - *b.* Bitter; caustic potash colours it yellow; obtained in crystals by dissolving in benzine and evaporating. *Residue of daphnine.*
   - *c.* Insoluble in ether.
     - *α.* Sulphuric acid colours it red-brown, tannic acid precipitates it. *Residue of quassine.*
     - *β.* Heated with dilute sulphuric acid, odour of menyanthole, liquid cloudy, and elimination of oily drops. *Major part of menyanthole.*
     - *γ.* Sulphuric acid colours it blood-red, then brown-red; hydrochloric acid greenish and brown on heating, cloudiness and elimination of oily drops. *Residue of cnicine.*
   - *d.* Soluble in ether.
     - *α.* Sulphuric acid colours it brown, afterwards blue-violet; sulphomolybdic acid same effect. *Residue of absinthine.*
     - *β.* Sulphuric acid colours it bright red, sulphomolybdic acid cherry-red, tannic acid precipitates yellowish-white. *Residue of colocynthine.*
     - *γ.* Sulphuric acid colours it brown, hydrochloric acid greenish, brown on heating, cloudiness and elimination of oily drops. *Major part of erythroecentaurine?*

B.—Agitation in Ammoniacal Solution.

I. *Benzine Residue Crystalline.*

1. Dilates the pupil.
   - *a.* Platinic chloride does not precipitate the aqueous solution; the sulphuric acid solution develops a characteristic odour on heating. *Atropine.*
   - *b.* Platinic chloride in sufficient quantity gives a precipitate. *Hyoscyamine.*
2. Does not dilate the pupil.
   Solution in sulphuric acid passes to blue with ceric oxide. *Strychnine.*

II. *Chloroform Residue.*

1. Sulphuric acid dissolves it in the cold without becoming coloured.
   - *a.* Solution colours a little on heating; after cooling is coloured violet-blue by nitric acid. Ferric chloride blues the substance, and sulphomolybdic acid colours it immediately violet. *Morphine.*
   - *b.* The solution on heating turns violet-blue. *Papaverine.*
2. Sulphuric acid colours it greyish-brown, and the solution on heating becomes blood-red. *Narceine.*

III. *Amylic Alcohol Residue.*

(This agitation is not performed unless the presence of salicine is suspected).

Sulphuric acid immediately colours it pure red. On heating with sulphuric acid and potassic bichromate, an odour of salicylic acid is developed. *Salicine.*

The characteristics designated in this table appear to be of such a nature as to afford an opportunity to discover the foreign substance which has served to give a beer the desired degree of bitterness; but they do not serve for the quantitative estimation of these substances, and even leave one in a state of uncertainty, unless the operations are repeatedly performed.

TEST PAPERS.*

BY F. MOHR.

For the preparation of litmus paper the author recommends that the litmus be washed with hot alcohol and then extracted with cold water. This extract may be brushed on writing paper on one side. The paper must be washed with water to remove free alkali or acid.

Turmeric roots contain two yellow dyes, one soluble in water and unaffected by alkalis, the other soluble in alcohol. The roots should be washed in water as long as the washings are coloured, and then exhausted with alcohol.

Paper soaked in potassium sulphocyanate or ferrocyanide may be used for the detection of iron.

Paper containing starch moistened with a solution of potassium iodate in oxalic acid, and dried, is turned blue by bodies which act as reducing agents, such as sulphurous acid, hyposulphites, sulphuretted hydrogen, potassium sulphocyanate, ferrous oxide, cupric chloride, potassium iodide, and similar bodies.

For oxidizing bodies a starch paper with potassium iodide may be used. To keep such paper unchanged, a lighted sulphur match should be held in the bottle in which the paper is preserved before closing the stopper.

The author also recommends the following test-papers:—For ammonia-gas: paper soaked in mercurous oxide solution. For sulphuretted hydrogen and alkaline sulphides: acetate of lead paper; filter-paper soaked in cobalt chloride; polished visiting cards known as "Polka papier;" paper painted with bismuth white.

For metals which give black precipitates with sulphuretted hydrogen in acid solution, washed sulphide of zinc precipitated from the acetate is smeared on writing paper and dried. Any mineral acid decomposes the sulphide of zinc, setting free sulphuretted hydrogen, which immediately precipitates the metals present.

The violet assumed by litmus in the titration of solutions which do not contain carbonates, is due to the carbonic acid contained in the litmus itself. If this be expelled by acidifying with dilute sulphuric acid and then boiling for some time, the litmus, after treatment with baryta water, changes from blue to red without any intermediate violet. In titrations with litmus, if the final colour is to be blue, blue litmus should be added first; if red, the red solution must be used. In this way all errors arising from the litmus itself may be avoided.

THE USES OF TURPENTINE AS A DISINFECTANT.

In a letter to the *Medical Times and Gazette*, from Dr. Thomas F. Wood, of Wilmington, North Carolina, occur the following remarks on the disinfecting properties of turpentine:—

"I have no experience with the use of the *odorous* essential oils as a means of disinfection, but I would like to make a remark upon the influence which the turpentine distilleries have upon the town in which I live. Wilmington, North Carolina, the town spoken of, is the great export market for oil, or "spirits of turpentine," as it is known in commerce, and also for tar, pitch, turpentine, and resin, the products of the extensive forests of *Pinus palustrio* which abound on the seaboard belt of all the Southern United States. This town is situated on the Cape Fear, a river which has a broad alluvial shore, and is subject to diurnal flooding by tide-water. The town itself is situated on a sand-ridge, and directly across the river to the west are extensive swamp rice-fields, not now under cultivation. During the late civil war, commencing in the early spring of 1861, all of the turpentine distilleries (which were located on the river-side in the town limits)—amounting to about six—were closed, and were not put in operation again until from 1866 to 1870. It had long been a popular theory that the health of the community was due to the resiniferous odours from these stills; and this opinion was shared by the medical men also. In 1862, these distilleries having ceased operations then for about eighteen months, a virulent epidemic of yellow fever broke out, having its origin, doubtless, by importation through the blockade, but owing its virulence and rapid spread to the insanitary condition of the town. True to the theory held as to the health-giving virtues of the resin and other products of the pine tree, barrels of resin were burnt day and night in the streets, covering the town with a funereal pall of dense black smoke. The only other notable epidemic was that of spotted fever (perhaps cerebro-spinal), which broke out in 1865, before the operations at the stills were recommenced. Previous to the establishment of distilleries in our midst—perhaps forty years ago—malarial fevers were very rife, but since that time they have prevailed to a less extent, and are more easily controlled by remedies.

"Another fact, bearing only an indirect relation to the above statement, is that during the civil war, when quinine was scarce, the surgeon-general of the Confederate States ordered experiments to be instituted at several of the large military posts, to prove whether or not oil of turpentine applied to the body by means of a broad band saturated with it, and worn around the abdomen, had any effect in cutting short the paroxysms of ague. Its effects were described as "marvellous," used in the cold stage of malarial fever, as endorsed by very many observers.

"It has long been the custom of the white proprietors of rice plantations in this section to move their families to the pine forests during summer and autumn, as there they enjoyed immunity from chills and fevers, so malignant upon their plantations. The theory that it is the resiniferous exudation from the *Eucalyptus globulus* which destroys malaria, seems to have abundant confirmation in the parallel of our North Carolina forests."

POTASSIUM IODIDE FROM CUPROUS IODIDE.*

BY M. LANGBEIN.

Cuprous iodide, which is imported in considerable quantity from Peru, contains from 60 to 70 per cent. of iodine, and furnishes a very suitable material for the preparation of pure potassium iodide.

In the author's process, this iodide is reduced to a fine powder, and suspended in water to which a few drops of hydrochloric acid have been added. It is then decomposed by a stream of sulphuretted hydrogen, and the excess of gas is destroyed by a solution of iodine in iodide of potassium, after the liquid has been decanted from the insoluble copper sulphide.

Potash, or potassium bicarbonate, according to the purity of the product required, is then added in sufficient quantity, and the whole evaporated till crystallization takes place. During the evaporation the suspended sulphur gathers together in balls, and sinks to the bottom.

The iron sulphate formed in the preparation of the sulphuretted hydrogen covers the expense of the acid and iron sulphide used, while the copper sulphate obtained by roasting the copper sulphide covers the other expenses. One point to be looked to is, to decant the liquid at once from the copper sulphide, as otherwise copper sulphate is formed by oxidation, and the final product rendered impure.

The Pharmaceutical Journal.

SATURDAY, JANUARY 16, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE NEW DRUG, JABORANDI.

IT was hardly to be expected that the surprising statements made by Professor GUBLER, in the early part of last year, respecting a new sialogogue and sudorific drug which he had received from Brazil, would escape the attention of therapeutists or pharmacists. The supply of the drug was so limited, however, and of such a nature, as to preclude more than conjecture as to its probable botanical origin, although sufficient to justify the hope that the South American Continent, which had already contributed so richly to the materia medica, was able to furnish yet another substance valuable in the treatment of the diseases "that flesh is heir to."

When, however, demands were sent to Brazil for a fresh supply, the difficulty commenced; for the name Jaborandi, so singular to English ears, is applied in that country to a large number of vegetable substances, many of which belonged to the Pepper family, and any of which might have been fairly forwarded under that name. By comparing the imperfect materials available, with Brazilian plants in his herbarium, Professor BAILLON was induced to regard Jaborandi as a Rutaceous plant, the *Pilocarpus pennatifolius* of Lémaire. We think we are justified in saying that none of the original sample forwarded by Dr. COUTINHO to Professor GUBLER reached this country in a state that would warrant an expression of opinion as to the correctness of Professor BAILLON'S determination. The fact that the predominant drugs known by the name of "jaborandi" belonged to the Piperaceæ, coupled with the negative results of some fresh leaves of *Pilocarpus pennatifolius* obtained from a plant growing in the Royal Gardens at Kew, created a strong suspicion that Professor BAILLON was mistaken, although, on the other hand, the physiological action of some of the Piperaceous substances were not found to coincide exactly with those attributed to the drug received from Professor GUBLER. We may remark in passing, however, that the non-development of an active principle in the Rutaceous plant when grown in a different habitat would have its exact counterpart in another new remedy from South America, Boldo, a plant of which, grown in Paris, is stated to have contained only a trace of the essential oil so abundant in the plant growing in its native home.

Within the last few days, however, there has been received in this country, from Pernambuco, a parcel of a "Jaborandi," the product of a Rutaceous plant, which we are given to understand, is, if not identical with the species indicated by Professor BAILLON, at least very nearly allied to it. Further, a rather venturous, but to some extent unintended experiment upon himself, which Mr. MARTINDALE describes on another page, shows that it possesses those remarkable physiological properties attributed to the drug used by Drs. COUTINHO and GUBLER, which, as it appears at present, render it unique. Without, therefore, arrogating to this particular drug the sole title to the name, we think it may fairly be assumed that this is *the* "Jaborandi" for which therapeutists and pharmacists have been looking.

We may mention that at the earliest moment steps were taken to put our readers in possession of authentic information respecting this latest novelty, and with this object Mr. HOLMES, the Curator of the Museum of the Pharmaceutical Society, has undertaken to draw up a detailed botanical description of the plant, and this, illustrated by a drawing of the plant, fruits, etc., will appear in the next number of the journal. Meanwhile it may be useful to indicate here what he has found to be some of the principal characteristics of the leaves, which are the parts used in medicine. The leaves are about nine inches long, and consist of from three to five pair of opposite leaflets, which are entire, with an emarginate or even retuse apex, and an unequal base. The texture is leathery, and when moistened the leaflet recalls in size and thickness the leaf of the cherry laurel. The veins are prominent on both sides of the leaf, and they branch from the midrib in a pinnate manner, remaining distinct until within one quarter of an inch of the margin of the leaf, where they become lost in the network of veinlets. When held up to the light the leaflets are seen to be densely pellucidly punctate. These pellucid dots, which are receptacles of secretion, are not arranged, as in another kind of Jaborandi, in lines along the veinlets, but are irregularly scattered all over the leaf, and appear equally numerous in every part. They do not appear to contain a volatile oil, and they impart very little flavour to boiling water. The matter contained in them is granular and may possibly prove to be of the nature of stearoptene. If this be the active principle it is obvious that the best menstruum has not yet been used, and this supposition is strengthened by the result of Mr. MARTINDALE'S experiment.

Some of the leaves originally supplied by Dr. COUTINHO were subjected to a chemical investigation by M. RABUTEAU, with results which were reported in this journal in May last (p. 911). M. RABUTEAU came to the conclusion that the Jaborandi leaves have an odour due to a volatile principle which is not analogous to the essential oils contained in aromatic plants; a bitter taste, due to a principle soluble in water and in alcohol, which can be separated easily by heating the aqueous extract of the leaves with alcohol; lastly that the leaves do not appear to contain any alkaloid. The chemical properties of the drug are, however, being investigated by Professor Attfield with a more ample supply of material than M. Rabuteau possessed.

LEAD IN AËRATED WATERS.

The recent prosecutions in the North for the sale of aërated waters impregnated with lead have excited a great deal of attention, and the paper on the subject read by Dr. Stevenson Macadam last week before the North British Branch of the Pharmaceutical Society is very opportune. Although the solvent action of water charged with carbonic or other acids upon lead was previously well known, Dr. Macadam has done good service by measuring the rate of this action, and demonstrating that aërated waters should never be allowed to come in contact with lead even if the lead occur only as an ingredient in the solder or block tin used in the construction of the apparatus. But if anything were wanting to justify the remarks made last week as to the propriety of analysts limiting their evidence to facts, it would be found in the hitherto unsuspected possible source of lead found in lemonade revealed by Dr. Macadam, who states that the oil of lemons employed in making up the syrup is "often loaded with lead;" this lead being derived from the lining of the copper drums or vessels in which it is imported. It is manifest that, in the present state of the law, this and the kindred contamination indicated by Mr. Ekin last week, may be a cause of serious inconvenience no less to the seller than to the consumer, and they present fair illustrations of cases where extra discretion should be used before initiating prosecutions. It is therefore satisfactory to note Dr. Macadam's statement that in Glasgow it was only after manufacturers had refused or delayed to remove lead pipes, and make other alterations which were necessary, that the authorities commenced the prosecutions.

THE CHEMISTS' BALL.

Whilst yet engaged in the festivities and social gatherings of Christmas and the New Year many pharmacists begin to look forward to the day when, according to what has now become an annual custom, they will have an opportunity of meeting their brother pharmacists and friends at the Chemists' Ball. In informing our readers that the Ball for 1875 will be held at Willis's Rooms, King Street, St. James's, on Wednesday next, we have a suspicion that we are doing something that is almost superfluous: we are therefore glad to be able to add that there is every promise at present of its being as successful as any of its predecessors. Tickets may still be obtained from the Stewards who form the Committee, a list of whom and other details will be found in our advertising sheet.

THE YEAR BOOK OF PHARMACY, 1874.

We are requested by the General Secretaries of the British Pharmaceutical Conference to state that the Committee of Publication regrets that the protracted illness of the Editor has somewhat delayed the issue of the Year Book for 1874. It is believed, however, that it will be ready for distribution before the end of the present month.

THE STORAGE OF DRUGS, ETC.

Price Currents and Trade Lists frequently evince much ingenuity and liberality on the part of those who issue them, in providing certain features that shall impart more than a passing interest to what would otherwise be "Dry-as-dust" catalogues. Messrs. Southall, Bros., and Barclay, of Birmingham, have forwarded to us a copy of their Monthly Price Current, in which the novel feature takes the utilitarian form of some very useful hints on the Storage of Drugs.

In his quarterly report to the Town Council of Bradford, Mr. F. M. Rimmington states that as Public Analyst he has examined during the last three months 41 samples of various articles, of which about one-fourth were adulterated. In the quality of the milk supply he has noted a considerable improvement. Pepper, however, in six cases out of thirteen, he found to be adulterated with pea meal and rice starch, and he considers it clear from the evidence adduced before the magistrates that the tradesman had been fraudulently imposed upon by two wholesale dealers in a neighbouring town. Referring to the conviction for selling a "Liquid Extract of Beef," which was not what it was represented to be, Mr. Rimmington says that the notice of appeal by the defendant has been withdrawn and all expenses paid.

L'Union Pharmaceutique reports the death by poisoning of a pharmacien, who, mistaking the bottle, took a dose of tincture of digitalis instead of his accustomed dose of cinchona wine.

At a recent Meeting of the New York Academy of Medicine a Committee was appointed to confer with the New York College of Pharmacy respecting the formation of a Botanic Garden in one of the public parks.

On Friday next, a Paper on the Aquarium as a Field for Microscopical Research will be read before the Queket Microscopical Club, by T. Charters White, M.R.C.S., F.R.M.S.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH, EDINBURGH.

The second meeting of the present session was held in the Society's rooms, 119a, George Street, on Thursday evening, 7th January, at half-past eight o'clock, Mr. William Gilmour, president, in the chair. There was a full attendance. The following communication was made:—

On the Presence of Lead in Aerated Waters,

BY DR. STEVENSON MACADAM, F.R.S.E., F.C.S.,

Lecturer on Chemistry.

Lately the action of aërated waters upon lead and the presence of lead in the aërated waters have been brought prominently before the public in connection especially with the prosecutions in Glasgow and elsewhere, under the Adulteration Act, and I have thought that the subject would prove of much interest to the members of the Pharmaceutical Society. I have therefore great pleasure in giving the results of a large number of observations which I have made on the subject, partly in connection with manufactories where I have been professionally consulted as to existing apparatus and necessary improvements, and in other part in respect to a lengthened series of experiments which I have made so as to determine the extent to which and the circumstances under which the aërated waters may be found to act upon lead and become impregnated therewith. The action of aërated water upon lead is one which is not new to me, because in 1871 I made numerous experiments on the action of hard and soft waters upon lead, and then observed that aërated waters acted powerfully upon lead, and in this way explained to some extent why hard natural waters which are highly impregnated with carbonic acid are often found to have more action upon lead pipes than soft waters which are comparatively free from carbonic acid. I have lately, however, supplemented these earlier trials by various series of experiments specially applicable to the presence of lead in aërated waters generally, including simple aërated or carbonic acid water, soda water, potash water, and lemonade.

The proportion of lead in the aërated waters manufactured and sold in Edinburgh within the last month was found by me to run from a mere trace up to one grain in the gallon. It is very seldom that the aërated waters have been found perfectly free from lead. The highest proportions I have detected were as follows:—

Aërated or Carbonic Acid Water	$\frac{1}{5}$	grain of lead to gallon.
Soda Water	$\frac{1}{5}$	„ „
Potash Water	$\frac{1}{5}$	„ „
Lemonade	1	„ „

In the estimation of these or similar small quantities in a single bottle of the water, the ordinary mode of determining quantities by the aid of the chemical balance would not be suitable, and the proportion is actually obtained by a series of colour tests which are applied to standard solutions of lead. One grain of lead is taken and dissolved in a few drops of diluted nitric acid, and the solution then mixed with water till the liquid has the capacity of one gallon. Such a solution will necessarily contain one grain of lead in the gallon of water. From this standard solution it is easy to make other standard solutions containing $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, $\frac{1}{10}$, $\frac{1}{20}$ grain, or other proportions to the gallon. These standard solutions are placed in large test-tubes about an inch in diameter and seven inches in length, and the liquids may be introduced to the extent of six inches in each. On adding acetic acid and thereafter hydrosulphuric acid and agitating, a more or less dark brown-black colour is produced, according to the proportion of lead. The reaction may be best observed by holding the tube above a sheet of white paper and looking down through the whole column of the liquid.

In this way a standard series of lead test-coloured tubes may be obtained for reference, and the amount of lead in any sample of aërated water may be determined by placing the liquid in a test-tube of similar size to the standard test-tubes, and adding the acetic acid and hydrosulphuric acid, agitating and observing the depth of the colouration produced.

The apparatus at present, and still more so, recently employed in the manufacture of aërated waters over the country, is and was the chief cause of the contamination of the liquids with lead. In some instances I have noticed that lead was employed in every possible place, and not a single piece of tinpipe or other precaution was adopted.

The gas generator is generally made of lead, and the pipe leading therefrom to the gasholder is also of lead. If a washer is introduced, it is likewise made of lead. If care be taken that the entrance gaspipe to the gasholder is a little apart from the exit gaspipe, and the gas be previously passed through a washer, or the entrance pipe be turned over so as to dip into the water in the gasholder tank, then I am of opinion that no harm may be apprehended from the use of lead in the gas generator or the pipe leading therefrom to the gasholder. The exit gaspipe from the gasholder to the receiver should however be of tin, and the mouth of the pipe should rise at least three inches above the highest possible level of the water in the gasholder tank. The gasholder and the tank should not be lined with lead or be painted with lead paint. The receiver is generally of copper, brass, or bronze, and is tinned inside, but the tinning is often done with very inferior metal containing much lead, and hence is a source of contamination of the aërated water. The pipe from the receiver to the bottling machine and all the pipes connected with the water supply and pumps should be of tin, and every coupling and pipe should be soldered with pure tin.

The non-observance of one or more of the above precautions has been noticed by me in some cases to lead to the contamination of the aërated water with lead. Of course, if the pipes are of lead, then the aërated waters must contain lead, but the missing out of any one of the following points may equally cause the waters to be impure:—

1. That the pipes be of pure tin, for many tin pipes contain more or less lead, and will contaminate the waters.

2. That the solder be pure tin, for plumbers' solder and tinsmiths' solder contain much lead, and it is difficult to get workmen to use pure tin.

3. That the gasholder and tank be free from lead, and the exit gaspipe be three inches above the possible level of the liquid in the tank.

4. That the water cistern be cleansed out every week with a soft brush so as to remove any sediment which may have accumulated and which often contains lead.

5. That the receiver be properly tinned with pure tin, and not with tin containing lead; and

6. That all the vessels and measures used in the mixing of the materials be of earthenware, glass or gutta-percha, and that no lead or soldered tin or copper vessel be employed.

In order to determine the extent of the action of the aërated waters upon lead, I made some trials in lead pipes, one inch in diameter and twelve inches long. In the first trial, the aërated waters which were free from lead to begin with—having been prepared at a manufactory which had been reconstructed under my direction—were firstly brought in contact with the lead for the shortest possible time, being merely poured in, and then thrown out again; secondly, were kept in the tube for one minute; thirdly for five minutes, and, fourthly, for one hour. The results of the respective experimental trials on the contamination of aërated or carbonic acid water, soda water, potash water, and lemonade, are given in the following table:—

Aërated or Carbonic Acid Water.

Poured in and out instantly . . .	$\frac{1}{10}$th	grain of lead.
Retained in pipe for 1 minute . .	$\frac{1}{2}$	" "
" " 5 " . . .	2	" "
" " 1 hour . . .	5	" "

Soda Water.

Poured in and out instantly . . .	$\frac{1}{20}$th	grain of lead.
Retained in pipe for 1 minute . .	$\frac{1}{5}$	" "
" " 5 " . . .	1·5	" "
" " 1 hour . . .	2	" "

Potash Water.

Poured in and out instantly . . .	$\frac{1}{20}$th	grain of lead.
Retained in pipe for 1 minute . .	$\frac{1}{5}$	" "
" " 5 " . . .	1·5	" "
" " 1 hour . . .	2	" "

Lemonade.

Poured in and out instantly . . .	$\frac{1}{2}$	grain of lead.
Retained in pipe for 1 minute . .	1·5	" "
" " 5 " . . .	4·5	" "
" " 1 hour . . .	10	" "

It will thus be observed that the lemonade had the most powerful action upon the lead, followed by the simple aërated or carbonic acid water; and that the soda and potash waters had a less but similar action.

The extent of lead surface exposed to the action of the various waters in the above experiments was certainly not large when compared with the amount of lead pipe present in the fittings of some aërated water manufactories; but in order that the observations might apply to those works where a small surface of lead was exposed, or where tin pipes were employed, and soldered in the ordinary way with tinsmiths' solder, containing about two parts of tin and one of lead, I instituted a more elaborate and complete series of experiments with small portions of metal of uniform size, so that the action of the different aërated waters upon the respective metals might be relatively determined.

A strip of sheet lead was taken, exactly one inch broad, and was scraped bright, and then cut into little pieces half an inch in length. These pieces presented a square inch of surface when both sides were allowed for, and they constituted the pieces of *bright lead* which are referred to in the tables which follow. A similar set of pieces of ordinary *tarnished lead* were cut off, and the edges were left *unprotected;* whilst a third set of pieces of ordinary *tarnished* lead were taken, and the fresh edges were protected by being dipped in melted beeswax. One bit of each of these pieces of metal was placed in each of a number of aërated water bottles, and the bottles were then charged respectively with aërated or carbonic acid water, soda water, potash water, and lemonade, which were free from lead. Two bottles of each kind were opened in a day and were examined for lead; the contents of the one bottle being used at once, whilst the contents of the second bottle were first boiled to expel the excess of carbonic acid, and then filtered before the test for lead was applied. A third bottle of each kind was opened in three days, and a fourth bottle in seven days. The results of all these trials as to the amount of lead dissolved by the waters are given in the following table in proportions of a grain of lead to the gallon of the respective waters:—

	Bright lead.	Tarnished lead with cut edges, unprotected.	Tarnished lead with cut edges, protected.
	Aërated or Carbonic Acid Water.		
1 day	$\frac{1}{10}$ grain	$\frac{1}{15}$ grain	$\frac{1}{20}$ grain
" and after boiling and filtration	$\frac{1}{13}$ "	$\frac{1}{20}$ "	$\frac{1}{30}$ "
3 days	$\frac{1}{3}$ "	$\frac{1}{3}$ "	1/[illegible] "
7 "	2 grains	$1\frac{3}{4}$ "	$1\frac{1}{2}$ "
	Soda Water.		
1 day	$\frac{1}{15}$ grain	$\frac{1}{20}$ grain	$\frac{1}{30}$ grain
" and after boiling and filtration	$\frac{1}{20}$ "	$\frac{1}{25}$ "	$\frac{1}{40}$ "
3 days.	$\frac{1}{4}$ "	$\frac{1}{4}$ "	$\frac{1}{5}$
7 "	$1\frac{1}{2}$ "	$1\frac{1}{2}$ "	1
	Potash Water.		
1 day	$\frac{1}{15}$ grain	$\frac{1}{20}$ grain	$\frac{1}{30}$ grain
" and after boiling and filtration	$\frac{1}{20}$ "	$\frac{1}{25}$ "	$\frac{1}{40}$ "
3 days	$\frac{1}{4}$ "	$\frac{1}{4}$ "	$\frac{1}{5}$ "
7 "	$1\frac{1}{2}$ "	$1\frac{1}{2}$ "	1 "
	Lemonade.		
1 day	$\frac{1}{5}$ grain	$\frac{1}{5}$ grain	$\frac{1}{8}$ grain
" and after boiling and filtration	$\frac{1}{5}$ "	$\frac{1}{5}$ "	$\frac{1}{8}$ "
3 days	1 "	1 "	$\frac{3}{4}$ "
7 "	3 grains	3 grains	$2\frac{1}{2}$ grains

From the above table it will be observed that the lemonade had the most powerful action on the metal, which was doubtless due to the combined action of the carbonic acid, citric or tartaric acid, and sugar. Aërated or carbonic acid water ranked next to lemonade, and the soda and potash waters were less powerful in their action but gave similar results. The effect of heating and filtering the liquid before testing for lead was to lessen the quantity in all the trials with aërated or carbonic acid water, and soda and potash waters, probably due to the disengagement of the solvent carbonic acid, but did not decrease the amount in the lemonade, owing doubtless to the acid character of the syrup keeping the lead in thorough solution.

A similar set of experiments were made on pieces of ordinary tin solder (2 parts of tin and 1 part of lead); plates of tin soldered with ordinary tin solder with the edges unprotected, and plates of tin soldered with ordinary tin solder with the fresh-cut edges protected with beeswax. Each piece of metal was one inch by half an inch, and therefore, as previously expressed, yielded a square inch of surface to the action of the aërated waters. The results are given in the following table:—

	Ordinary tin solder.	Tin plates soldered and edges unprotected.	Tin plates soldered and edges protected.
	Aërated or Carbonic Acid Water.		
1 day	$\frac{1}{9}$ grain	$\frac{1}{30}$ grain	$\frac{1}{30}$ grain
" and after boiling and filtration .	$\frac{1}{12}$ "	$\frac{1}{40}$ "	$\frac{1}{40}$ "
3 days . . .	$\frac{1}{2}$ "	$\frac{1}{10}$ "	$\frac{1}{10}$ "
7 " . . .	$2\frac{1}{2}$ grains	$\frac{1}{5}$ "	$\frac{1}{5}$ "
	Soda Water.

These results show a powerful action of the various waters upon the solder, and a much smaller action upon the soldered tinplates. As before, the lemonade acted most decidedly, followed by the aërated or carbonic acid water, and thereafter by the soda and potash waters.

Taking all these experimental trials into consideration, it is manifest that no lead, or solder containing lead, should ever be allowed to come in contact with any of the aërated waters, and that for the future all aërated water manufacturers should arrange their apparatus to ensure that the waters are perfectly free from lead.

The materials employed in the manufacture of aërated waters are sometimes impregnated with lead. Even the water may contain the lead derived from the pipes from which it is drawn from the well or other source, and this contamination of the water will be more likely if the water is impure from the presence of nitrates derived from sewage. The cleansing of the lead cistern every week should not be neglected, and where practicable the substitution of a slate cistern would be advisable. No charcoal filter should be employed, for such more often conveys impurity to the water than removes it. A sand and gravel filter may be advantageously employed, provided the sand and gravel are thoroughly washed before being used.

The carbonate of potash sometimes contains iron, but I have never found lead in it. The iron may lead to a fictitious appearance of the presence of lead by darkening with the hydrosulphuric acid, unless the acetic acid has been previously added in decided excess, so as to render the potash water decidedly acid.

The oil of lemons employed in making up the syrup is often loaded with lead. In some cases a few drops added to ten ounces of water, and agitated so as to mingle the oil thoroughly with the water, will communicate sufficient lead to give a dark brown with the test, and a small quantity of the same oil of lemons burned off in a porcelain basin will leave a yellow residue of oxide of lead. It is seldom that the oil of lemons is free from the lead, and I have no doubt that part of the lead which has been found in lemonade has been derived from the oil of lemons employed in making up the syrup. The oil of lemons in its turn obtains the lead from the lining of the copper vessels or drums in which it is sold, and which, in many cases, are tinned in the interior with a thick coating of inferior tin containing a large proportion of lead.

The *syphons* now used in many places for the retention of aërated waters introduce a fresh element of contamination, for the metal covers generally consist of a compound of tin and lead, resembling solder, and hence the aërated waters, when enclosed in these *syphon* bottles, continue to act upon the metal top when the liquid touches it. There should be no difficulty in making the tops of pure tin, and thus ensuring that the aërated waters be not contaminated in this way.

It is satisfactory to know that in the recent prosecutions in Glasgow, the manufacturers of aërated waters were not taken by surprise, for a warning was given to each by the inspectors, and it was only when manufacturers refused or delayed to remove lead pipes, and make such other improvements as to ensure that the aërated waters could be prepared free from lead, that the authorities then raised the prosecution. This is the proper spirit in which to carry out the Adulteration Act, especially in a field where ignorance prevailed as to the existence of the adulteration or contamination.

During the course of the paper Dr. Macadam tested many samples of aërated waters, and practically showed the mode of analysis of lead and tinpipes, solder, etc., as also the extraction of the lead from the oil of lemons, and from the lining or tinning of the drums in which the oil of lemons is brought to this country.

This paper was listened to with much interest, and at the close Mr. Baildon observed that he was sure all present must have been both interested and instructed by the exhaustive series of experiments shown that evening by Dr. Stevenson Macadam, to elucidate the fact of lead being so frequently found present in aërated waters, a subject which was at the present time undergoing a searching inquiry, which must result in benefiting and protecting the public. The discovery of a large quantity of lead in essence of lemon, acquired from the lining of the copper canisters in which the essence is always imported, was, he believed, entirely the result of Dr. Macadam's researches, and would help, although only in a slight degree, to explain the fact that it is found most difficult to manufacture lemonade that does not show a trace of lead. Every manufacturer of aërated waters was bound to take all the precautions in his power in order to obtain absolute freedom from this deleterious metal. In his own case the pipes through which the gas passed were of pure tin, and he employed pure india-rubber tubing for the water, and the solutions of soda and potash and earthenware tanks, so that neither the carbonic acid gas nor the alkaline solutions came in contact with a particle of lead.

Mr. W. Leitch, on being called upon, replied that he should speak with great diffidence, because until recently he did not think it at all possible that aërated waters could have been contaminated to such a degree with lead. Lately, however, he had instituted a series of experiments which agreed substantially in all respects with Dr. Macadam's results, with the exception of the oil of lemons, which he never suspected. With regard to working materials, he was of opinion that the acid generally used in generating the carbonic acid gas was very much too strong, producing an intense degree of heat, and probably evolving other gases than the one desiderated, besides having an undoubtedly prejudicial effect on the different parts of the apparatus, especially the gasometer. Again, he was of opinion that the condensers or receivers were in many cases (especially in Edinburgh) much too large; better results were almost invariably obtained with the smaller condensers and at a much smaller expenditure of power. At the same time he thought that for extra safety, work should never be commenced in the morning without first running off the water which might have lain overnight in the receiver or pipes—of whatever metal they might be composed—because one point which Dr. Macadam had apparently overlooked, was the fact that the couplings and valves were in many cases sources of danger. These parts of the apparatus were composed of what was popularly termed gun-metal, that is a combination of copper and tin, but which he found were frequently corroded or eaten away, showing evidence of some other metal in the composition (evidently lead or inferior tin or zinc). Mr. Leitch had also found a considerable amount of metallic refuse in dissolving bicarbonate of potash *in a mortar*. This salt was purchased as the manufacture of the most popular and well-known chemists in this country. The metal he at first surmised to be lead, but now believed it to be iron, but could not say how introduced; he was now having it tested for satisfaction. Mr. Leitch, in conclusion, said he was glad to learn from Dr. Macadam that the recent prosecutions in Glasgow had been conducted in a fair spirit, and that due notice had been previously given to each party that the apparatus was unsatisfactory, and that time had been given to make the necessary alterations. He hoped the Edinburgh authorities would show equal courtesy, as he was aware that great exertions were at present being made to secure perfect purity, by all the manufacturers in town; and at least two of these had already been *sampled*.

The chairman made a few observations on the importance of the subject, and concluded by moving a vote of thanks to Dr. Macadam for his able communication. This was seconded by Mr. H. C. Baildon, and carried with acclamation.

The following remarks were then made on

Jaborandi.

BY DR. CRAIG, F.R.S.E.

(*Lecturer on Materia Medica.*)

Dr. Craig exhibited a small quantity of the bruised leaves of Jaborandi, and also a little of an infusion which he had prepared from the leaves of this remarkable plant. He stated that Jaborandi was the name given to a remarkable medicine obtained from the leaves of a shrub from the interior of Brazil.

The medicine was said to be a powerful diaphoretic and sialogogue, and Professor Gubler, of Paris, and others had tested its virtues in the Paris hospitals, and pronounced its effects in these respects to be most wonderful. Up to the present time very little of this medicine had found its way into Europe, and what little had been received had been confined chiefly to Paris.

Dr. Craig stated that it was only on Tuesday last that he had obtained a small quantity of the drug through a friend in London. All that he could procure was one drachm of bruised leaves. This he carefully infused for two hours in a cupful of boiling water, and after it became cold he drank it, and carefully noted the effects produced. These were well marked and extremely interesting. In twenty minutes after the medicine was swallowed there came on an abundant perspiration over the forehead and trunk of the body, extending to the limbs, but most marked on the trunk. The temperature of the body remained normal throughout, showing that the perspiration was not due to increase of temperature. In all likelihood it acted by direct stimulation of the sweat-secreting glands.

Its power as a sialogogue was most wonderful. Simultaneously with the perspiration the saliva commenced to flow abundantly, and in little more than two hours he collected fully ten ounces of fluid from the mouth. He stated that he knew no medicine at all to be compared to Jaborandi as a sialogogue. Although he had only as much of the drug as enabled him to perform a single experiment, yet the results obtained were so well marked that there can be little doubt but Jaborandi is at once a powerful diaphoretic and one of the most powerful of sialogogues.

Dr. Craig remarked that the leaves being bruised he had no means of determining the species of this remarkable plant. He mentioned, however, that he had lately seen a dictionary of Brazilian medicines, published in Portuguese by a Dr. Chernoviz in 1868, and that it was there mentioned that *Jaborandi* was obtained from a plant belonging to the *Piperaceæ*, and that its root possessed sialogogue properties. He also mentions that a tincture is prepared from the roots (1 of the root to 8 of alcohol), and that this tincture is used as a sialogogue. Dr. Craig considered that it would be most interesting to determine whether or not the Jaborandi of Dr. Chernoviz was the same as the Jaborandi at present attracting so much attention in Europe.

Mr. Mackay proposed a vote of thanks to Dr. Craig for bringing the matter before the meeting, remarking that the extremely high price at which Jaborandi was now introduced would in all probability follow the example of such articles as Calabar bean, kousso, and other new drugs which at first were exceptionally dear, but soon found their level. Mr. Mackay further expressed a hope that Dr. Craig might be able, at an early meeting, to give a more extended account of the Jaborandi, and the likelihood of its being recognized as a valuable therapeutical agent.

The vote of thanks was carried very unanimously.

The Secretary then intimated the following donations to the library and museum:—

For Library:—'Thomson's Annals of Philosophy.' 16 vols. All bound. From Mr. D. R. Brown. 'Phillips's Annals of Philosophy.' 12 vols. All bound. From Mr. D. R. Brown. 'The Pharmaceutical Journal,' from Toronto, for December.

For Museum:—'Rangoon Petroleum.' Presented by Sir Robert Christison.

Seventy-six specimens of Common Metals employed in Pharmacy. From Mr. D. R. Brown. The following is a list:—

Bismuth.
Sulphate of baryta.
Black manganese.
Manganese ore.
Pyrolusite-binoxide of manganese. No. 1.
Pyrolusite-binoxide of manganese. No. 2.
Crystallized oxide of manganese.
Manganese.
Oxide of manganese.
Gold and silver stone.
Pearl spar and blende (Iceland).
Alloy of zinc and iron.
Sulphuret of zinc, (zinc blende,) Alston Moor, Cumberland.
Blende and pearl spar.

Lead Ores. Carbonates or sulphates (?) and phosphates.

Phosphate of lead, etc.
Lead ore, sulphuret of lead, Alston Moor, Cumberland.
Galena.
Plumbo-calcite, a new discovery, partly coated with oxide of manganese, also galena.
Galena and carb. of lime.
Carb. of lead, or sulphate encrusted with phosphate.
Pearl spar and galena.
Galena-sulphuret of lead.
Orange phosphate of lead.
Arseniate and phosphate of lead.
Phosphate and arseniate of lead.
Galena, or sulphuret of lead, (Silver mine, Linlithgow).

Copper.

Copper pyrites.
" " bisulphuret of copper.
Black sulphuret of copper—copper glance.
Sulphuret of copper. No. 1.
" " No. 2.
Jarrow copper process, No. i, ii, iii, iv, v, vi, vii.
Copper slag.
Silicate of copper in slag from ore furnace.
Fibrous malachite.
Native copper.
Copper, uncrystalline slag.
Carbonate of copper.
Copper ore.
Native copper with ore of copper.
Carbonate and sulphuret of copper.
Moss copper.

Peroxide of tin from Cornwall.
Oxide of tin.
Tin ore, 120 Fm., Huel Vor Breage.

Orpiment?
Ore of Arsenic.
Realgar.

Native alum.

Antimony.
Sulph. antimony. No. 1.
Sulphuret of antimony. No. 2.

Iron.

Sulphate of iron.
Slag formed when fluxing with limestone and coal.
Native carbonate of iron, (Renfrewshire.)
Iron pyrites in quartz containing trace of gold.
Carbonate of iron with lime, (Durham).
Iron ore.
Sulphuret of iron.
Sesquioxide of iron.
Specular iron ore.
Titaniferous iron?—slag.
Iron pyrites.
Carbonate of the protoxide of iron.
Peroxide of iron.
Phosph. of iron.
Pure iron.
Cleveland ironstone.
Muscle band.
Iron stone.
Clay iron stone.
Iron bolts from Bellrock lighthouse, changed by the action of sea water.
Chrome iron ore, chromate of iron.
Clay iron stone.

Special thanks were voted to the contributors, but particularly to Mr. D. R. Brown, who has so often enriched the Museum and Library by presenting specimens and books.

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

At the meeting of the above Society on the 2nd December, under the presidency of M. Planchon, it was announced that a communication had been received from M. Stanislas Martin upon Tayuya root, which he believed would prove of great service in the treatment of syphilitic disorders. M. Martin promised to present specimens at the next meeting.

The Society proceeded to the election of a Vice-President and a Secretary for the ensuing year; M. Coulier being elected to the former, and M. Fr. Wurtz to the latter office.

M. Vanflart presented a specimen of iron ore from Dulette (Manche), which was stated to contain 70 per cent. of the pure metal.

M. Petit described some new experiments which he had made respecting the sugar contained in vine leaves. Testings by Fehling's liquor, controlled by fermentation and polarimetric examination before and after inversion, had shown that the leaves contain a mixture of a reducing and a non-reducing sugar. The proportion of the non-reducing sugar, which presents all the properties of cane sugar, equals in certain cases three-fourths of the whole sugar present, which varies from 20 to 25 grams per kilogram of leaves. Further experiments had led him to conclude that in the melon the reducing sugar is converted at the point of maturation into non-reducing sugar, and he stated that he had observed the same change to take place in a fruit detached from the plant before it had completely ripened.

M. Buignet said that there existed a very great difference in the saccharine matter of fruits, according as it was produced under the influence of the vegetative forces or irrespective of their influence. Experiment had shown that the sugar which continued to form in bananas after they were detached from the tree was no longer cane sugar, but inverted sugar.

After the close of this discussion the Society voted a sum of 250 francs towards the fund for the erection of a monument to the memory of Scheele.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture I.

The History of Alcohol in Relation to some of its varied Services to Mankind in the Arts and in Science.

(*Continued from p.* 559.)

Distillation.—I have said that for many centuries there was nothing known to mankind beyond the formation of a vinous fluid. At length a new process was brought to bear on wine, which simple as it is to us now, was in its early days, and for many long days afterwards, a wonder and a mystery. This was the simple act of distilling wine, and of obtaining from it by distillation a fine spirit containing no water. The discovery of distillation of wine has been attributed to Albucasis, or Casa, an Arabian chemist and physician of the eleventh century. The evidence on this point is not very convincing. It is true that the refined body called spirit of wine began to be known in the alchemical and Arabian schools about or soon after the time of Casa, and from that circumstance rather than from direct evidence derived from his works, the discovery has probably been imputed to him. However, it is historically correct that from the school of Albucasis the discovery sprang. The alchemists or adepts were conversant with pure spirit, and, says Boerhaave, when they had reduced it to the utmost subtlety, they made use of it in the preparations of all their secret menstruums.

Distillation itself was probably an imitation of nature, for nature is ever distilling and condensing. In the cold, water condenses on the leaf and on the grass, as dew, and ascends as vapour in the sun. This process of raising water into a state of vapour by heat, and condensing it by cold, the simplest of immediate imitations of nature, would by easy transition pass to other liquids, and with special ease to that liquid which has rivalled water as a drink for man—wine.

The pure spirit of wine in its earlier use was applied mainly to chemical and medicinal purposes, and indeed many centuries elapsed before the process of distillation became active for the production of those stronger drinks, which, under the name of "spirits," are now in such common use in daily life. Brandy, from *brennen*, to burn; thus *brantwein*, brandy, is a comparatively late term in European literature. Gin, contracted from Geneva, is not to be found as signifying a spirituous drink in our vocabularies of two hundred years ago. The term rum is assigned to the native American peoples, who so designated the vinous spirit distilled from sugar; and whisky (Celtic *usige*) water, though it may have been known as a distilled drink as long as brantwein, has not been Anglicized, I believe, for more than a century and a half.

In the earlier mode of distillation the instruments used were simple but effective. They consisted of the furnace, the receptacle to the furnace, the receiver which stood within the receptacle, and the alembic or condenser, which was made of tin or other metal.

The ancient alembic was a very scientific instrument, and caused a perfect collection of the distilled fluid. The spirit from the crude wine ascended from the heated reservoir into the conical tube, and then downward through the returning exit tube into the receiver.

The adepts were, indeed, marvellously mechanical, and when we recall that they neither had cork nor elastic tubing, nor gas, we wonder by what clever devices they were so successful. They had many useful arts, I am sure, which we have improperly forgotten, and which might with advantage be revived. Some of their plans, for a long time thought to be fanciful and useless, are being again considered of value. There is an instrument called a cohobator, and another is called a circulator, in which they caused spirits to boil and distil, and condense and distil again, for months, in some cases. The fluids went round and round in the circulator like the wheel of fortune, and many an adept has looked upon his fortune as spinning in that wheel, from which the elixir of life and the philosopher's stone were, in his ardent imagination, to be evolved. These and several other similar instruments, for which I am indebted to Mr. Robbins, of Oxford-street, are on the table before us.

To sum up, let us remember the four stages in the general history of alcohol, from the first to the time when it came strictly under analytical chemical observation, and, in regard to common knowledge, to the present time.

(*a.*) The stage of manufacture of wine or beer by fermentation. A stage standing from the earliest history until the time of the adepts, say about the eleventh century of the Christian era.

(*b.*) A stage when there was distilled from the wine a lighter spirit called, first, spirit of wine, and afterwards alcohol.

(*c.*) A stage when this subtle or distilled spirit from

* Cantor Lectures: delivered during December, 1874, January, 1875, from the *Journal of the Society of Arts.*

wine was applied in its refined or impure state to the arts and to science.

(*d.*) A stage when this same process of distillation was applied to the production of alcoholic spirits for the use of man as spirituous drinks, under the name of brandy, gin, whiskey, rum — a stage comparatively modern.

Uses of Wine.—We will, if you please, leave now for a time the consideration of wine and alcohol as drinks, and dwell briefly on the uses to which these fluids have been applied for other purposes. The study is peculiarly interesting, and I could easily carry you on during the whole course of these lectures with the narration of it. Unfortunately, every word I have to say must be introduced into this hour, so that I can refer only to the salient points, and to a few only of these.

From the first, the preservative or antiseptic quality of wine was recognised, and the fluid was employed for the preservation of animal and vegetable substances. The Roman butchers, who, like our modern butchers, sold their fresh and their salted meats, prepared their salted flesh in the following manner :—The animals they intended to preserve were kept from drinking any fluid on the eve of the day on which the killing took place. After the killing, the parts to be preserved were boned and sprinkled lightly with pounded salt. Then, having well dried off all dampness, the operators sprinkled more salt, and placed the pieces so as not to touch each other, in vessels that had been used for oil or vinegar. Over the whole they poured sweet wine, covered the contents of the vessels with straw, and, when they could, kept down the temperature of the room in which the vessel was placed by sprinkling snow around. When the cook wished to remove the salt from the meat, he took it out of the wine and boiled it first in milk and afterwards in rain water.

Long previous to the Roman era this preservative process of wine had been recognized and applied. Palm wine was used by the Egyptians in their most costly processes of embalming the bodies of the dead. This same application of wine, or spirits of wine, for the preservation of animal and also of vegetable substances, has been maintained up to our time. In our museums the specimens therein preserved, in the moist state, are immersed in spirit, and the modern art of embalming is not perfected without the employment of the same antiseptic agent.

Early after the discovery of the properties of wine the fact must have been observed that from a change in it another substance was producible, to which, in these days, we give the name of vinegar. To prevent the formation of vinegar in wine the ancients boiled the wine, and to remove the acidity arising from vinegar they added gypsum to sour wine, and thus rendered it palatable. Vinegar itself they employed for purposes precisely the same as we in this day ; they partook of it with vegetables, they employed it for preservation of animal and vegetable substances, and they applied it for numerous medicinal purposes. After the process of distillation was discovered by the adepts, the distillation of vinegar was also carried on, and in this way was obtained that strong vinegar which enters so largely into various uses as an acid, called aromatic vinegar.

Very early in history wine was employed for another purpose, that, namely, of extracting the active principles from plants and other substances possessing, or supposed to possess, medicinal virtues. Dioscorides, one of the fathers of medicine, and particularly of that part which pertains to the use of curative substances, or medicaments proper, is full of descriptions of vinous tinctures, some of which were sufficiently potent even for our present use. On the table before us is a vinous tincture of this kind, which has a singular and, I had almost said, romantic history. This is the wine of Mandragora. In the isles of Greece there has grown for ages a plant called mandrake ; it belongs to the same family of plants as our belladonna, or deadly nightshade. From the root of this plant the Greeks extracted, by means of wine, a narcotic, and what in this day we should call an anæsthetic. Some, says our learned Dioscorides, boil the root in wine down to a third part and preserve the decoction, of which they administer a cyathus, about what would now be a common wineglassful, for want of sleep, or for severe pains of any part, and also before operations with the knife or cautery, that these may not be felt. Again, he says, a wine is prepared from the bark without boiling, and three pounds of it are put into a cadus (about eighteen gallons) of sweet wine, and three cyathi of this are given to those who are cut or cauterised, when, being thrown into a deep sleep, they do not feel any pain. Again he speaks of a preparation of mandragora, called morion, which causes infatuation, and takes away the reason. Under the influence of this agent the person sleeps, without sense in the attitude in which he took it, for three or four hours afterwards. Pliny, the Roman historian, much later, bears evidence to the same effect, and adds the singular remark that some persons have sought sleep from the smell of this medicine. And again, Lucius Apuleius, the author of the book called the 'Golden Ass,' who lived about 160 A.D., and of whose works eleven editions were republished in the fourteenth and fifteenth centuries, says that if a man has to have a limb mutilated, sawn, or burnt, he may take half an ounce of mandragora in wine, and whilst he sleeps the member may be cut off without pain or sense.

It is unquestionably to this same anæsthetic wine our own Shakespeare refers in his half-imaginary, half-legendary Middle Age history. This is the wine of that insane root, which, says Macbeth, "takes the reason prisoner." This is the wine that Juliet drinks, and the action of which the Friar Lawrence describes—

> "Through all thy veins shall run
> A cold and drowsy humour, which shall seize
> Each vital spirit ; for no pulse shall keep
> His natural progress, but surcease to beat.
> No warmth, no breath, shall testify thou liv'st,
> The roses on thy lips and cheek shall fade
> To paly ashes ; thy eyes' windows fall
> Like death when he shuts up the day of life ;
> Each part, deprived of supple government,
> Shall stiff, and stark, and cold, appear like death :
> And in this borrow'd likeness of shrunk death
> Thou shalt remain full two and forty hours,
> And then awake as from a pleasant sleep."

It follows therefore from the history of scientific discovery that our modern great advance of removing pain during surgical operations is in fact, if not as old as the hills, as old almost as wine. But is the story true, you say ? I answer yes, and the answer is from experiment. Thinking it a subject of very great interest, I instituted, a few years ago, an inquiry into the matter. Through the kindness of my friend, Mr. Daniel Hanbury, F.R.S., I obtained a fine specimen of mandragora root, and I made once again, probably after the lapse of five centuries, mandragora wine. I tested this and found that it was a narcotic, having precisely the properties that were anciently ascribed to it. I found that in animals it would produce even the sleep of Juliet, not for thirty or forty hours, a term that must be accepted as a poetical license, but easily for the four hours named by Dioscorides, and that in awakening there was an excitement which tallies with the same phenomenon that was observed by the older physicians.

Thus, one of the first uses of wine to man was amongst the most noble and beneficent that man, by his ingenuity, can confer on his kind, and if wine had ever been used in this way and in none worse, Pater Lenæus might have retained his supremacy in the good opinion of all the world.

Besides using wine for extracting the virtues of the vegetable kingdom, our ancient chemists tested it on metals, and made it here subservient to their purpose. What they called the extract of Mars was a solution of iron made with an astringent wine, and reduced into a thick consistency by fire. Eight ounces of the rust of iron, powdered very fine, were put into an iron pot, and covered with four pints of strong red wine. The iron crucible was then set on the fire, and the mixture, stirred with an iron rod, was boiled to a third; then it was strained through a cloth and evaporated into an extract. To this extract wonderful curative powers were ascribed, and indeed it was a very useful medicine. The metal antimony also was subjected to the action of wine. The so-called liver of antimony was treated with white wine, and dissolved in it: to this day we retain the remedy. It was originally called the emetic wine.

Uses of Spirit of Wine or Alcohol.—After the process of distillation of wine was discovered, the use of the new spirit rose rapidly into application in a variety of ways. The adepts, the Middle Age chemists of whom I have spoken, kept this distilled spirit long a secret. They found in it a solvent for many things that before were insoluble. Oils, resins, gum resins, balsams were now brought into a medium that acted towards them as a menstruum, and straightway they were dissolved. The East India Styrax Benzoin yielded a balsam which, dissolved in the distilled spirit was a fortune to the chemists. The Commander's balsam, or balsam for wounds, or Friar's balsam, was soon the reputed heal-all of every injury.

The useful first extracted out of the new distillate, beauty was next remembered. Alas for the female face divine, the cosmetic and the subtle wash that should veritably make young faces old and assumably make old faces young, were soon in process in the laboratory of the adept who could distil wine. Again, the artist came in for a share in the discovery. The once insoluble and useless resins and ambers were dissolved for his brush, and gave him coatings, preservatives, and washings, of which previously he had no conception.

This spirit of wine burns. It does not touch oil for the light it gives, but how strange! it burns away without a trace of smoke, and with an excellent heat. So the spirit lamp in due time is invented. A trifle, say you? Nay, it was as great an advance to the chemist who first used it as the gas in the Bunsen burner is to us.

Once more; this subtle spirit has in it the virtue of preserving all organic substance with which it is brought in contact. It masters putrefaction itself; perchance the elixir of life is therefore found. It dissolves insoluble bodies; perchance it will by careful study and experiment reveal the grand secret of transmutation. In this way reasoned its first masters.

I must not dwell longer over these details of minor things of major usefulness. I must turn to some applications of our refined spirit which are major in fact as well as in use, in theory as well as in practice, in science as well as in art. In this regard we have to consider alcohol as the basis of other essences not less potent than itself.

The process of distillation of essences from liquids and from vegetable substances once established, it was but natural that some adept should turn his hand to mineral bodies and try if they would not yield some new product that should be of effective and novel quality. Into the distillatory soon pass, therefore, all manner of things, from the horn of the stag or hart, to the skull and brain of the dead man. Among other substances, there was submitted to distillation this green stony crystal found in the earth, and called green vitriol, in Latin *vitriolum*. The result of the distillation of this *vitriolum* was to obtain as a yield, in the retort, the heavy oily corrosive fluid called, originally, spirit of vitriol, called now oil of vitriol or sulphuric acid.

Many were the fanciful things thought of by the adepts concerning this oil, and even to the letters of which the word *vitriolum* is made up they attached a mystical symbolism. In course of time they began to combine and to distil other fluids with the corrosive sulphurous oil, and amongst the first of fluids used in this manner stood spirit of wine. The experiment did not deceive them, for it gave them as a product one of the most useful and wonderful of liquids. To them this new liquid as it first was taken from the retort was an infinite marvel. They poured it on water and it floated, on spirit and it floated. They poured it into their hands, and, lo! it boiled there. It escaped from them into an invisible state or air before they could well bottle it; it burned and exploded. It caused, when it passed off from the surface of the living body, an intense cold. It dissolved wax, oil, fat, gums, resins, balsams, and yet when it was set free it let them fall again. It was so light that a measure which would hold twenty pounds weight of water would only hold seven pounds of this light intangible liquid. What name shall they apply to this substance, the lightest known? They designate it by a term indicating the lightest thing they can conceive: they compare it with the refined medium, with which the philosophers imagine the firmament to be filled, and they give it the same name. They call it *æther.*

Of what strange after use this magical fluid has been to man we all know. It was introduced early into medicine, and was well studied last century by Dr. Ward, and by Mr. Turner, of Liverpool. In our own time, it has been discovered to have the power of suspending sensation and sensibility after being inhaled by the lungs, and by its means there has been re-introduced to the world that beneficent and long-lost art of rendering the body insensible to pain during surgical operations.

More recently, by a study of the application of ether for the production of intense cold, I myself introduced that local use of it for benumbing the body, called the ether spray.

The value of this secondary alcohol to man is indeed inestimable. You know how valuable it has been in photography as the volatile solvent of collodion, and in other various departments of the fine and useful arts it has rendered equally good service.

From the distillation of *vitriolum* our adepts soon passed to other solid substances. They distilled saltpetre, and so got the spirit of nitre, which we call now nitric acid; they distilled common salt in combination with oil of vitriol, and so got spirit of salts (marine acid), which we call hydrochloric acid. Again, with these new spirits they distilled spirits of wine to obtain new ethers, nitrous, and marine. Then a chemist, the Count de Lauragnais, distilled together acetic acid and spirit of wine, by which process he obtained acetous ether. Thus by these double actions, a numerous series of useful ethers has been obtained, it were too long for me to enumerate.

From the observation of the fermentation of wine we derive, in a certain sense, our first knowledge of gases. Van Helmont gave to the gas which comes from the fermenting of vegetable matter the name of *gas sylvestre*, and from this may be dated the origin of the study of these invisible forms of matter. Priestley made some of his early observations on the gas which escaped from fermenting malt in a brewery at Warrington, and was led step by step to the liberation of gases from mineral and earthy substances, and so to the discovery of oxygen. Upon that discovery, coupled with his method of collecting gases by displacement of water, and of trying their qualities, came the process of distilling and collecting a gas from coal, and thus coal gas.

After the discovery of the element known as chlorine, and of the compounds of that element with other elements, another new era was opened in the history of alcohol. By passing chlorine through alcohol, Liebig obtained that narcotic substance which we call chloral hydrate; and by treating alcohol with chloride of lime, the same great experimentalist produced for us chloroform, an agent which has rivalled ether in its service as a soother and saver of pain. If you glance at the table of anæsthetics or sleep producers which is before you, you will see by the names in italics those substances which come from alcohol. All that have proved of most use excepting one, nitrous oxide or laughing gas, have this common origin.

List of Substances that will produce Anæsthetic Sleep.

Nitrous oxide gas	Tetra-chloride of carbon
Carbonic oxide gas	Heavy carburetted hydrogen gas
Carbonic acid gas	*Olefiant gas or ethylene*
Bisulphide of carbon	*Ethylic, or absolute ether*
Light carburetted hydrogen	*Chloride of ethyl*
Hydride of methyl or marsh gas	*Bichloride of ethylene* (Dutch liquid)
Methylic alcohol	*Bromide of ethyl, or hydrobomic ether*
Methylic ether gas	Hydride of amyl
Chloride of methyl gas	Amylene
Bichloride of methylene	Benzol
Terchloride of formyl, or chloroform	Turpentine spirit

Had the time not been expended, I could have brought before you further illustration upon illustration of these secondary uses of alcohol to man; but I must stop, content in having recalled to your minds some of the more striking facts in the history of the curious and important agent which is now the subject of our studies.

Parliamentary and Law Proceedings.

Poisoning by a Soothing Syrup.—Censure of a Chemist and Druggist.

On Wednesday, January 6, an inquest was held in Sheffield, before the deputy coroner, B. Bagshawe, Esq., upon the body of Elizabeth Connor, five days old. The evidence showed that the child being very restless, and crying almost continually, and its mother being very ill and not expected to recover, the father wished to give the child something to keep it quiet, so that it should not annoy its mother. At the recommendation of some neighbours, he went to the shop of Mr. Atkinson, Meadow street, and a bottle of anodyne was given to him. He administered about a quarter of a teaspoonful to the child, and in a short time afterwards it fell asleep. It was taken to Mr. Reckless's surgery, and that gentleman ordered them to keep the child awake. This they endeavoured to do, but were unsuccessful, and the child died on Sunday afternoon.

John Townsend, the father, said when he bought the medicine, the assistant who served him did not tell him that the mixture was poison, and he believed that he told the assistant that the medicine was for a young child. In answer to the Coroner, he said he was unaware that all soothing syrups, etc., contained poison.

Mr. G. K. Thorpe, surgeon, who had made a *post-mortem* examination, stated that the brain and lungs were much congested, which was consistent with poisoning by opium or morphia. It was exceedingly difficult to trace the action of poison, but he could readily believe that death had been caused by the child taking a dose of medicine containing opium or morphia. He could not account for death in any other manner.

George Hogg, assistant to Mr. Atkinson, said he did not remember selling the cordial produced to the man Townsend; but on a Saturday he generally sold between thirty and forty bottles of the same mixture to children of all ages. The anodyne cordial contained not quite one grain of opium to the ounce of mixture. The bottle was not labelled "poison," because he did not look upon the cordial as a poison. It contained less opium than most of the preparations of the present day.

The Coroner, in summing up, said the Jury could not but return a verdict that the deceased had died from an overdose of poison, administered by John Townsend, without any felonious intent; but they must also consider whether it was not their duty to add something by way of censure upon Mr. Atkinson, the druggist, for allowing the anodyne cordial to be sold without the label "Poison" being pasted on the outside. He read the Act of Parliament, to the effect that all opium, or preparations of opium, must be labelled "Poison" before they were sold. Mr. Atkinson had clearly offended against the provision, and if they thought proper to censure him, he would see that the case was reported to the proper authorities. The poisoning of infants was a very serious thing; in fact, it was carried on by wholesale. There were, at least, twenty fatal cases of that kind in Sheffield every year, and numerous cases occurred in which constitutions were ruined and the foundations of disease laid.

The jury concurred in the remarks of the Coroner, and returned the following verdict, "That the deceased died from an overdose of opium, administered without any felonious intent, by John Townsend; and the jurors are further of opinion that Mr. Atkinson is highly censurable for selling a preparation of opium without the same being labelled poison."—*Sheffield Evening Star.*

Poisoning by a Liniment.

On Saturday, January 2, Mr. Carter held an inquest at Kingston, Surrey, respecting the death of Mrs. Sawyer.—Mary Ann Sawyer, daughter-in-law of deceased, said she was on a visit to her mother, who was very ill, and had a draught to take, and some liniment to apply outwardly. Witness gave her the draught on Sunday night, and they all went to bed at half-past ten. About half-past twelve she was aroused by deceased moving, and saw her with the bottle containing the liniment up to her mouth, drinking from it. Witness asked her what she was doing, and she said she had a pain in her side. Witness took the bottle from her, knowing it contained poisonous liniment. Deceased had drank nearly all the liniment.

The bottles which had contained the medicine and liniment were produced; they were nearly alike in shape, but the liniment bottle bore the word poison on it in red letters. This label, however, the witness said, was not on the bottle when deceased drank the liniment; it had been put on since. She believed deceased drank it in mistake. Deceased died an hour after she had drank the liniment, before any medical assistance could be obtained.

Mr. J. Hill Turner, assistant to Mr. Shirtliff, surgeon, deposed that he was called to deceased early on the 28th ult., and found her dead. He had treated her medically for intercostal neuralgia, and supplied her with liniment, the active ingredients in which were chloroform and aconite, both deadly poisons. The bottle contained 1½oz. of liniment, and when deceased was dead, he saw that it was empty.

The Coroner: Was the bottle when you saw it in the state it is now?

Witness: No, it had not got that label on. I had supplied some liniment of the same description before, and there was a label on that. I did not put a label on this bottle.

The Coroner: How do you account for that?

Witness: I expect it was an oversight. I put the label on afterwards.

The Coroner: Why did you put it on afterwards,—it was rather foolish of you, and a great reflection might be thrown upon you for it.

Witness: I acknowledge it was so.

Mrs. Sawyer, recalled, said that deceased knew the liniment was poison, although she could not have read the label had there been one on it.

In reply to the coroner, Mr. Turner stated that he believed the chloroform in the liniment was the cause of death.

The Coroner then cautioned Mr. Turner never to send out poisonous mixtures again without a label.

Joseph Sawyer, husband of deceased, also deposed that deceased knew the bottle contained poison; but he thought she took the bottle for the one containing medicine.—A verdict was returned of Death by Misadventure.—*Surrey Comet.*

THE FATAL CASE OF POISONING BY CORROSIVE SUBLIMATE.

The inquest touching the death of Celine Marin, whose death had been caused by corrosive sublimate administered to her in mistake for bismuth, was resumed on Monday last, before Mr. Holl, coroner, at St. Thomas's Hospital. Sheppard, the coroner's officer, stated that, assisted by the police, he had made inquiries, and he could not find that the housekeeper, Mrs. Kant, had sold poisonous drugs to any other person, and he had no evidence to offer on that point; but he believed she had a number of persons present to speak on her behalf. Kilian Kupitz stated that he is a member of the Pharmaceutical Society of Great Britain. About three months ago he was engaged by the executors of Mr. Ungerer, chemist, to carry on his business, at No. 18, Rathbone-place. Mrs. Kant, the housekeeper, did not serve in the shop beyond selling soaps and scents, and simple things of that kind. She never sold poisons. Witness was never there on Sundays, and was told by his employer that on Sundays no business was done at all, unless in cases of emergency. He did not know who did it then. He was told that Mrs. Kant served this powder. If any one came Mrs. Kant would attend to the bell, and send the person to Oxford-street to another chemist there. A Juror: Did you prepare the bismuth that was in the bottle for retail sale?—No, it was old stock. Coroner: Did you see a bottle labelled bismuth in the shop?—No. Did you ever sell any bismuth there?—No, I was never asked for it. And never made up a prescription with bismuth in it?—No. Then you did not do much business?—No. Did you ever see a bottle there labelled hyd: bichl:?—Yes. Did it contain corrosive sublimate?—I did not analyse it; it contained a whitish powder. Did you ever sell any of it?—No. The coroner said the more he went into this case the more he was dissatisfied with it. He had received a letter from the registrar of the Pharmaceutical Society in reference to it. By the Pharmacy Act no person was allowed to sell poisonous drugs unless he was registered under that Act, and it was only by such cases as these coming to the Registrar's knowledge that he could carry out his duties. The coroner thought that this case should be further investigated, and should be adjourned for that purpose. The inquest was then further adjourned until Monday next.

THE SALE OF ARSENIC.

The following account of the prosecution of a chemist and druggist for an illegal sale of arsenic, has been sent by a correspondent, and has been cut from a local paper:—

At the Lanchester Petty Sessions, before M. Kearney (chairman), A. H. Talmadge, Hy. Smith, and John Clavering, Esqs., David Imrie, chemist and druggist, Front Street, Consett, was summoned for selling a quantity of arsenic, and neglecting to enter the same in a book that should have been kept by him for that purpose.—William Todd, miller, stated that in September he went to Mr. Imrie's shop and got threepenny-worth of arsenic, which was supplied by Mr. Imrie himself. Witness did not sign a book because the shop was full of people and Mr. Imrie was busy.—Mr. Imrie admitted that the book was not signed. He believed the reason Mr. Todd did not sign the book was that he (Mr. Todd) was in a hurry.—Mr. Talmadge (to Mr. Todd): Had you got arsenic at Mr. Imrie's shop before?—Mr. Todd: No. Mr. Talmadge: Had you ever bought arsenic at any other shop?—Mr. Todd: No. Mr. Clavering (to Mr. Imrie): If a stranger came to your shop and asked for arsenic would you give it to him?—Mr. Imrie replied that he would not; he knew Mr. Todd. Mr. Clavering: What did Todd want the arsenic for?—Mr. Imrie: Mr. Todd said his place was infested with rats, and as I had previously heard that this was the case, I had no scruple in letting him have the arsenic. Mr. Smith (looking at a packet containing arsenic): Are you in the habit of selling pure arsenic?—Mr. Imrie: No.—Mr. Smith: Is this mixed?—Mr. Imrie: No; that was for rats. People generally ask for it mixed with soft soap, but as Mr. Todd asked for pure arsenic I let him have it. Mr. Smith: According to the Act you are not justified in selling pure arsenic for rats.—Mr. Imrie said he usually mixed it with soft soap. Mr. Talmadge: You have no right to sell it with soft soap even. Mr. Clavering: Can you sell Battles' Vermin Killer without the book being signed?—Mr. Imrie replied in the affirmative. Mr. Clavering said he very much questioned his right to do so.—Mr. Smith thought he could not, as it was strychnine.—The Chairman said it was perfectly manifest that Mr. Imrie understood his duty. They did not intend to inflict a severe penalty, but as an example to others he would have to pay a small fine of 1*s.* and the expenses.—Mr. Smith: It is as well you should know that you are not allowed to sell arsenic unless it be mixed with soot or indigo.

POISONING BY CHLOROFORM.

An inquest was held at Woolton, on Friday, January 8, respecting the death of Samuel Healey. It appeared from the evidence that deceased had suffered from asthma and toothache, and had been in the habit of inhaling chloroform for the purpose of inducing sleep. On Friday morning he did not make his appearance as expected, and on entrance being gained to the room through the window he was found dead, with a handkerchief having chloroform on it over his mouth. The medical evidence was to the effect that death had resulted from an over-inhalation of chloroform, and the jury returned a verdict accordingly.—*Liverpool Daily Post.*

BOOK RECEIVED.

A MANUAL OF HYGIENE, PUBLIC AND PRIVATE, AND COMPENDIUM OF SANITARY LAWS, for the Information and Guidance of Public Health Authorities, Officers of Health, and Sanitarians Generally. By CHARLES A. CAMERON, Ph.D., M.D., etc. Dublin: Hodges, Foster, and Co. London: Baillière, Tindall, and Cox. 1874.

Notes and Queries.

[423]. BLACK HAIR DYE.—Would you please give me a recipe for a good black Hair Dye, that will not stain the skin, and free from the unpleasant smell of, the sulphuret of ammonium.—THOS. ROBINSON.

[*₊* In his little book on 'Diseases of the Hair,' Dr. Benjamin Godfrey says he has experimented with the following, and found it successful:—

"Dissolve ten grains of bichloride of mercury in three ounces of rose water; dip a brush in this solution, and apply it twice a day to the hair for a week. The head should previously be washed in weak soda and water, and dried. The mordant should be used in the same way, but not with the same brush, for a day or two, and a black colour will be produced. The mordant is made by dissolving an ounce of hyposulphite of soda in two ounces of water."]

Obituary.

We regret to have to announce the death, on Saturday, the 9th inst., of Mr. William Forbes, Pharmaceutical Chemist, of Reading, at the age of 77 years. Mr. Forbes was a Founder of the Pharmaceutical Society, and for many years acted as one of its Local Secretaries.

Notice has also been received of the death of the following:—

On the 30th December, 1874, Mr. William Charles O'Reilly, Pharmaceutical Chemist, of Shepherd's Bush, London. Mr. O'Reilly had been a Member of the Pharmaceutical Society since 1856.

On the 8th January, 1875, Mr. George Wood, Chemist and Druggist, of Long Row, Sheffield.

Correspondence.

Hours of Business in Pharmacy.

Sir,—Illness has caused my attention to be only just drawn to a second letter from "An Examined Assistant." To him, he says, "my words seem to be those of a man who has been in a trance for twenty or thirty years." My friends, on the contrary, seem to think that I have been decidedly "wide awake" during that time; but let that remain a moot point,—he may be wiser than they. It is quite possible that, as he intimates, "the apprentices" of "the good old times," as it is phrased, would be "nowhere" in "the dreaded room of Bloomsbury Square." Nevertheless it is a fact—let "An Examined Assistant" explain it if he can and choose—that many employers seeking assistants prefer *not* to have a "Square" man.

"An Examined Assistant" does not evince intelligence when he professes to see no difference between a chemist's business and that of grocers, drapers, and ironmongers, in the matter of early closing. If this evening I find that I want a lock, my wife a piece of calico, and the cook a bladder of lard, but the respective shops where these articles are sold are closed, each can and doubtless will be procured on the morrow. It is not so with physic: two sleeping draughts will not be taken the next night to make up for the one missed on this; and occasionally it would happen that if the requisite medicine could not be obtained over night the patient would in the morning be found in a condition to dispense altogether with physic for the future.

"An Examined Assistant," if intelligent, must know that in disease exacerbation generally recurs towards night. The physician must frequently pay late visits to his patients, and if the physic he prescribes is to be made up at druggists' shops, such shops cannot be closed as early as, and with the regularity of those of grocers, drapers, and ironmongers. Those who urge it prove themselves that it cannot be done. Mr. A. W. Waring, writing from Bedford, says an assistant stops in every evening after the shops are closed. The public of Bedford know well that they can obtain physic after the shops where it is sold are ostensibly shut up: it is not so with their cheese or their ribbon. By-the-bye, does Mr. Waring speak to the card when he says most of the establishments in Bedford have three or four assistants? I knew it some years since as a thriving town, but I had no idea of the extent of prosperity which this statement goes to shew it has since attained. In the city from whence I write half the establishments can boast of no assistant. Young men seeking where to commence business will assuredly have their attention directed to that evident *El Dorado*, and a rapid migration to Bedford may be looked for.

The only way to ensure everywhere such early closing as is clamoured for, would be for employers and *employés* to combine to get an Act of Parliament compelling all medical men "to do their own dirty work," by making up their own prescriptions and rendering it imperative on physicians to send theirs to apothecaries, and so relieve druggists from the infliction; and then the business might be more closely assimilated with other "trades." But I am afraid there would not be found sufficient unanimity to ensure such "a pull altogether" as might effect so excellent an object. One man elects the medical profession for his future career, his brother the legal. This is not disturbed by clients after 5 p.m., that is at the beck and call of his patients all hours of the twenty-four; and it would be just as reasonable were he to clamour to his patients to be as considerate of his time and comfort as his brother's clients are of his, as it is for druggists to clamour for the same early and regular closing, *i. e.*, cessation from work, as "drapers, etc." A pharmaceutical chemist's business has its advantages and its things agreeable; it has, also, its disadvantages and things disagreeable. These can be ascertained by youths going out into the world, and if they think the former are more than counterbalanced by the latter, let them select the hat business, or the drapery or grocery trade, as the stage for the future display of their alents and ability, if they would prefer either. It may be asked what advantages being a pharmaceutical chemist has over being a hatter, etc.? It gives a man possessed of sufficient mental ability, more interesting and intellectual occupation than fitting hats to heads, or measuring ribbon, or weighing pounds of sugar. It gives him a better social position, and as time rolls on it will give him a better one still. It is a business in which a young man with £200 or £300 to commence with, may confidently hope to retire on £500 a year by the time he is forty, or on £1000 by the time he is fifty; and he is not nearly so likely to do that either in the hat, drapery, tea, or ironmongery trade. But there is one qualification absolutely necessary to enable him to accomplish this: he must be a man of business, and it is quite possible for him to pass through the terrible ordeal of "the dreaded room with a smiling face," and write himself both "minor" and "major," and yet be as far removed from that as the poles are sundered.

In all my experience—a varied one—I never knew an instance in any establishment, when trade was so "slack," and "stock so well up," that there were no "wants" on "the want paper." The text, "no man can serve two masters," could not be better applied than to the assistant who would vainly endeavour during the day to be alternately serving his employer and himself. He would soon be found "holding more to one" than "the other," and a very slight knowledge of human nature will tell which "one" that would be.

I believe in an improved future for druggists, not in the shape of early closing; there cannot be much effected in that direction, any more than doctors can close early, especially if druggists in the future are to prepare more instead of less of their prescriptions. But the effect of stringent examinations, and the necessity for a more expensive education, will be, that druggists will not increase in an equal ratio with the population; it will follow that establishments will become larger and more profitable, and employers will get much of the work which has hitherto been done by assistants — laboratory work, etc. — performed by labour more cheaply purchased.

VERITAS.

12th January, 1875.

A. S. A.—The Assistant's Certificate of the Apothecaries' Company does not confer upon the holder a right to keep an open shop as a chemist and druggist.

"*Dispenser*" (who should have sent his name).—We think you have committed an error, and have little doubt that Acetum was meant.

R. J. M.—The green iodide should be dispensed. The dose is a small one, but that would not justify any deviation from the prescription.

J. S. R.—We know of no better method than the one mentioned.

J. Robinson.—Yes, in quantities of not less than ten pounds, and under the conditions prescribed in the Arsenic Act.

K. K.—Mucilago Acaciæ, using as small a quantity as possible.

"*Digitis.*"—We have been unable to obtain a formula for Mapson's Salve.

C. M. P.—Pereira's 'Selecta è Prescriptis,' published by Churchills.

A. Manning.—A large number of salts occur in the natural Carlsbad water, of which sodium sulphate, carbonate, and chloride are present in the largest proportions. Analyses of the water will be found in the Appendix to Squire's 'Companion to the Pharmacopœia.'

A. B. C.—(1) We believe that Bentall's botanical drying paper may be obtained from Mr. Van Voorst, Paternoster Row. (2) No.

M. R. P. S. is referred to the rule respecting anonymous communications.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. Bartlett, Quaerens, Mr. Leifchild.

THE BOTANICAL SOURCE OF JABORANDI.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

Having lately had the opportunity of examining a quantity of Jaborandi from Pernambuco, through the kindness of Messrs. Hearon, Squire, and Francis, I was fortunate enough to find several ripe fruits of the plant. These fruits are distinctly Rutaceous in their character, and enable me to confirm Professor Baillon's conjecture that they belong to that natural order, and probably to a species of *Pilocarpus*, which, if not identical, certainly comes very near to the *P. pennatifolius*, Lémaire.

The specimens of the plant which I examined appear to belong to a shrub about five feet high. The root is cylindrical, hardly tapering at all, nearly three quarters of an inch in diameter for the first twelve inches, and very sparingly branched. The bark of the root is of a pale yellowish-brown colour, about one line in thickness, and has a very short fracture. The outermost layers are very thin and papery, and are frequently exfoliated. A small portion of this layer placed under a microscope forms an extremely pretty object, and is seen to consist entirely of strongly reticulated dodecahedral cells. The odour of the root is like that of a mixture of bruised peapods and orange peel. The taste is at first like that of green peas, but this soon disappears, and gives place to a tingling sensation, which is much more powerful than that produced by the leaves or bark of the stem, and endures for a considerable time. By gaslight the transversely-cut surface of the bark is seen to sparkle with minute crystals.

The stem is half an inch in diameter near the root, narrowing to a quarter of an inch in the upper branches. The bark is thin, of a greyish-brown colour, longitudinally striated, and sprinkled over in some specimens with a number of white dots which are not lenticels, but the remains of old oil receptacles. The bark of the stem is thin and fragile, and readily scales off when the stem is broken or bent; it has a short fracture, and is yellowish-white internally; its inner surface sparkles with minute crystals; it has not, to any appreciable extent, the peculiar leguminous taste of the root. The wood of the stem is yellowish-white and remarkably fibrous. The stem is alternately branched at a very acute angle (about 20°), the branches being erect and furnished with alternate leaves. The leaves, one of which is represented in fig. 1, are imparipinnate, about nine inches long, with from three to five pair of opposite leaflets, which are articulated to the rachis and have very short slightly swollen petiolules, those of the upper leaflets are about one line long, those of the lowest leaflets about three lines long, and the terminal one has a petiolule from half to one inch long. The rachis of the leaf is swollen at the base. The pairs of leaflets are usually about $1\frac{1}{4}$ inch apart, the lowest pair being about four inches from the base of the rachis.

The leaflets are very variable in size, even on the same leaf. Their general outline is oblong-lanceolate. They are entire (fig. 2), with an emarginate or even retuse apex, and an unequal base. Their texture is coriaceous, and when moistened reminds one in size and thickness of the leaf of the cherry laurel. The veins are prominent on both sides of the leaf, and branch from the midrib at an obtuse angle (about 60°) in a pinnate manner, remaining distinct until within one quarter of an inch of the margin of the leaf, where they become lost in the network of veinlets. The midrib is scarcely prominent on the upper, but forms a distinct keel on the under surface of the leaflet. When held up to the light the leaflets are seen to be densely pellucidly punctate. These pellucid dots, which are receptacles of secretion, are not arranged, as in another kind of Jaborandi, in lines along the veinlets, but are irregularly scattered all over the leaf, and appear equally numerous in every part; they are mostly rather large, but vary a little in size. The whole plant is glabrous.

I may remark here that there appear to be two varieties, if not species, of this *Pilocarpus*, the one being perfectly smooth in every part, as above described, and the other having the stems, petioles, and under surface of the leaves covered with a dense velvety pubescence composed of simple hairs. The hairs are not so numerous on the leaves and lower part of the stems, but appear to be singularly persistent, as they may be found on the bark for a considerable distance down the stem when it is examined with a lens. In shape and size the leaves resemble those above described, but are rather thinner in texture, and have a somewhat different and less pungent taste. The lowest pair of leaflets in the specimens I have examined are only two to three inches from the base of the rachis. I have not succeeded in finding entirely glabrous leaves on the stems which have hairy leaves, nor hairy leaves on the stems which have smooth leaves, and therefore consider that the plant with hairy leaves is probably a distinct variety.

The inflorescence is a raceme, six or eight inches long, judging from the peduncle figured on p. 582. The base of the peduncle there represented is entire, but the top is evidently broken off, so that it may have been one or two inches longer. The pedicels, so far as can be learned from the scars on the peduncle, are numerous and about three-eighths of an inch apart. Whether they are horizontal or not when flowering it is impossible to say. The only two specimens I have seen are in fruit and have the pedicel deflexed and about half an inch long. The fruit, fig. 3, closely resembles in external appearance that of a specimen of a Cuban plant in the British Museum,* referred by Asa Gray to *Pilocarpus heterophyllus* (Pl. Wrightianæ, p. 170; Wright, 1129). When perfect it consists of five carpels, of which not more than two or three are usually developed to maturity. When ripe the carpels dehisce into two valves, as in fig. 5, and then remind one strongly of miniature cockle shells, fig. 4, with the valves open exposing the animals.

This appearance is owing to the fact that as in two or three other closely allied genera, the endocarp separates at a very early stage, and thus forms an inner case for the seed, as represented in figs. 5 and 7. The outer portion of the carpel, consisting of the united epicarp and mesocarp, is in most of the specimens of a pale brown or buff colour, coriaceous, convex on both sides, of a somewhat circular form, but with the inner edge (*i. e.*, that nearest to the stigma) nearly straight, marked both inside (fig. 6) and outside (fig. 4) with curved ridges, which anastomose towards the outer edge and are almost absent from the inner edge. The convex surfaces only are dotted with oil

* The genus *Galipea*, to which *P. heterophyllus* has been referred, is distinguished from *Pilocarpus* by the convolute cotyledons, tubular flowers, and anthers not versatile.

JABORANDI (*Pilocarpus species*).

1. An entire leaf. 2. Leaflet: under side, showing the venation. 3. An entire fruit and peduncle—nat. size. 4. Ditto with two carpels only developed, showing the deflexed pedicel. 5. Carpel, showing the dehiscence. 6. A carpellary valve with the endocarp removed, showing the reticulated inner surface. 7. Endocarp, showing the dilated placenta and short funiculus. 8. Placenta separated. 9. Seed: *a*, hilum. 10. Endocarp without placenta. 11. Cotyledon.

receptacles. The endocarp (fig. 10) is smooth and pale yellow, with a wide sinus in the inner edge, which is occupied by a membranous expansion (fig. 7) of the shape shown in fig. 8. To the upper portion of this expansion, which appears to be a dilatation of the placenta, the seed (fig. 9) is suspended by a narrow, lancet-shaped, extremely short funiculus; this is shown in fig. 5. The seed, of which there is only one in each carpel, is black and shining, somewhat reniform, convex on both sides, enlarging towards its base, and forming a sharp ridge at the back towards the apex.

The hilum is lancet-shaped, the vessels appearing to pass through its lower end (fig. 9 *a*). The testa is thick and coriaceous, the endopleura membranous. The seed is inverted, somewhat reniform in outline, with a superior radicle, plano-convex cotyledons, and is exalbuminous, the radicle being very minute (fig. 11).

The genus *Pilocarpus*, to which our plant has been referred by Professor Baillon, was limited, as originally defined by Vahl* to plants with simple leaves, and seeds having biauriculate cotyledons. As further extended by Bentham and Hooker in their 'Genera Plantarum,' p. 299, the plants of the genus *Pilocarpus* are said to have "simple, ternate, or *pinnate* leaves," while no mention is made of the cotyledons being biauriculate. The seeds, however, are stated to be ovate, with a membranaceous testa, and exalbuminous.

The Jaborandi plant differs from the description of the genus, as defined in the 'Genera Plantarum,' only in the following particulars:—the seeds are somewhat reniform, not ovate, and the testa is coriaceous, not membranaceous. The cotyledons are not auriculate, but as that character is not given as an important one, it alone is not sufficient to exclude the plant from the genus.

Since there are several genera closely allied to *Pilocarpus* in the tribe (*Zanthoxyleæ*) to which Jaborandi evidently belongs, it will not be possible, until the flowers of the Jaborandi plant have been examined, to decide with certainty whether it belongs to the genus *Pilocarpus* or not, for the above-mentioned differences can scarcely be considered sufficient to separate it.

Whether it be identical with the *Pilocarpus pennatifolius* of Lémaire is more doubtful for the following reasons:—

The fruit of Lémaire's plant has not, that I can discover, been described.

The plant of *P. pennatifolius* at Kew, which is without doubt Lémaire's plant, has a much longer and stouter raceme (2-3 times the diameter and nearly twice as long) than that of the Jaborandi; and has quite a succulent appearance.

The leaves of Lémaire's plant are of much thinner texture than those of the Jaborandi, and the veins on the upper surface are much less prominent; the leaves also taper below much more rapidly than in the Jaborandi.

The geographical distribution is different. Lémaire's plant, so far as it is known, is extra-tropical, while the Pernambuco plant comes from near the Equator.

Hairs do not appear to be present even on the youngest leaves of the smooth variety of Jaborandi, but are stated by Lémaire to be present in the young parts of his plant.

It appears probable, therefore, that the Jaborandi of Pernambuco is a species of *Pilocarpus*, which, judging from the materials at present examined, comes very near to the species suggested by Professor Baillon, although probably distinct from it.

The hairy variety of Jaborandi seems to come much nearer in the texture of its leaves to *P. pennatifolius*, Lémaire, but from the persistence of the hairs, even upon the grey bark, I am inclined to think it also a distinct plant.

Whether these conjectures are correct or not can however only be decided by the arrival of flowering specimens of the plant, which I hope, through the kindness of Mr. W. Squire, to have the opportunity of examining during the present year. Still it is a satisfaction to have been able to describe the characters of the fruit thus early.

As there are several plants used in South America under the name of Jaborandi, which seem to possess somewhat similar properties in varying degrees, I think it will be well in future experiments to distinguish the Jaborandi here described and figured as Pernambuco Jaborandi. Another species, which is in use both in France and this country, is a kind of *Piper*. It is readily distinguished from the Pernambuco Jaborandi by the thin texture of the leaf, which is acuminate, and has pellucid dots so minute as not to be visible to the naked eye when the leaf is held up to the light.

LEAD IN AËRATED WATERS.

BY C. UMNEY.

As the manufacture of aërated waters is carried on to some extent by pharmacists, any remarks having a practical bearing either upon the method of their production, or the analysis of specimens as met with in trade, must be of interest, not only to those actually engaged in their manufacture, but to druggists generally.

There can be no question that the recent prosecution in Glasgow under the Adulteration Act, for the sale of soda-water contaminated with lead, must be followed by most beneficial results, for already it would seem chemists have been consulted upon the purity of the water supply, the determination of the presence or absence of lead, and other matters which manufacturers have thought it advisable to place beyond suspicion.

The publication of the results of these investigations in our journals is unquestionably in the main a great boon, for the truth must be told even though unpalatable; but one cannot help thinking that this increase in our list of substances contaminated with lead, and more especially so when essence of lemon and such simple bodies are included, must have a tendency to produce with the trade and even the public, a lead panic.

Mr. Ekin* has recently pointed out in this Journal that citric acid, as generally met with in trade, contains traces of lead, a statement which will be believed by anyone acquainted with its manufacture.

I myself have lately examined two specimens from different sources and find both slightly contaminated, and not only citric, but tartaric acid too is liable to contain the same impurity.

Dr. Macadam's recent elaborate research into the

* *Pharm. Journ.*, Jan. 9.

solvent action of water containing carbonic acid upon lead under varying conditions, has added very much to our information upon what *may* take place under certain circumstances.*

My object is not to question the figures given in the paper alluded to as the results of examination of the waters sold in Edinburgh, or to say anything against the very excellent general suggestions for the erection of soda water plant there detailed. On the contrary, I should strongly recommend them to any one fitting a new factory; but still I do venture to put before the readers of the Journal, my views upon the cause of lead contamination, where the aërating and bottling machines used are such as are made by London engineers; for of those produced in Glasgow or other Scotch cities, I have no knowledge, although I imagine they are of the same construction and upon the continuous principle, as devised in the early part of this century by Bramah.

Of course, manufacturers, whilst desirous of perfecting their processes and attaining purity, will still be anxious to disturb their present arrangements of plant only so far as absolutely necessary. I would therefore indicate where they *should* begin, also the exact point at which they *may* cease removing leaden pipes.

London machines are generally made and adapted as follows:—

The leaden generator for carbonic acid, is in communication by a leaden pipe with the washing vat, where it is connected to a tinned copper pipe, passing upwards through the water, ending in a bend, which is several inches below the surface; the washed gas is carried away by another tinned copper pipe, which is several inches above the surface of the water; and as this leaves the vat, it is then attached to a leaden pipe, which often passes several yards along the ground, until it is beneath the machine, when it is bent in the upward direction, and connected by a gun metal union and tinned copper pipe to the aërating cylinder, which is always of copper or gun metal, in either case tinned inside.

A check valve is inserted between the leaden pipe and the cylinder, which allows the gas to pass at each stroke of the pump, but having passed and come in contact with the water, it cannot return, for the greater the pressure on the interior of the cylinder, so much greater the force on the top of the valve.

Now, as the cylinder is of copper or gun metal, tinned on its interior, and only in this cylinder is there any liquid, any lead contamination up to this point must be from the passage of the washed carbonic acid gas through the leaden pipe.

The question then naturally arises, Is it possible for gaseous carbonic acid to pass through a leaden pipe without contamination?

In order to test this, I caused one thousand litres of carbonic acid to be drawn by a pumping machine through one litre of distilled water, to which a small quantity of acetic acid had been added. Upon boiling the solution to expel carbonic acid, treating with hydric sulphide, not a trace of lead sulphide was discernible, the colour of the liquid remaining perfectly white.

It would therefore appear that aërated water does not, up to this point, receive its contamination from the aërating machine, or the pipes leading to it.

* *Pharm. Journ.*, Jan. 16.

Were all waters bottled direct from the cylinder, there would be no fear of contamination, but it is customary to transfer the liquid to the bottling machine.

In its transit it receives its contamination, for the connection is made with leaden pipe, which is acted upon (more especially when the pressure is from four to eight atmospheres), under the most favourable circumstances that could be devised.

For this reason, therefore, I would strongly recommend all manufacturers to replace the pipe leading from the machine to the bottling apparatus by one of pure tin; and in the erection of all plant for the future it would certainly be advisable, considering that the extra cost could only be an additional two or three pounds per machine, and even if only to be *beyond suspicion*, to use tin pipes throughout, as Dr. Macadam has suggested.

We are told essence of lemon "is often loaded with lead, and that no doubt part of the lead which has been found in the lemonade has been derived from the oil of the lemons in making up the syrup."

Surely this can hardly be intended in earnest, even although the essence may contain traces of lead?

In the London market, essence of lemon is met with in copper canisters, tinned internally, weighing from forty to eighty pounds, a layer of lead being added on the inside to strengthen the thin copper used. To describe the essence "as loaded with lead," is, according to my experience, an exaggeration. The solution of sufficient lead necessary "to load" the essence would with eighty pounds weight of it show a marked decrease in the weight of the copper, which in practice is not found to be the case.

That traces of lead are present I have satisfied myself, but when one considers that the amount of lemon which is used in flavouring syrup seldom exceeds 0·15 per cent., and that this syrup is only used in very limited quantity, it is difficult to believe that the indication of lead in lemonade is due to this cause, but rather to the contamination of the citric and tartaric acids in the first instance, a point which seems to have escaped Dr. Macadam in reading his paper at Edinburgh.

The discontinuance of the use of leaden pipes from the aërating to the bottling machine, will, I am confident, do all that is practically necessary to perfect the manufacture of aërated waters. It is to be hoped that public analysts will refrain from magnifying these infinitesimal contaminations into adulterations, for should they act otherwise, the public will at length become so exacting that trading in articles of high commercial purity, although not of absolute chemical purity, will be simply impossible.

Laboratory, 40, *Aldersgate Street, E.C.*

JAPANESE VEGETABLE AND BEES' WAX.

Mr. Consul Robertson in his report on the trade of Kanagawa, Japan, gives the following information respecting the vegetable and bees' wax of that country:—

"The trees from which wax is made are the urushi, or lacquer tree, the yama-urushi, the hage-urushi (the last-mentioned better known as the rô-no-ki), and the koga-no-ki. The wax is made from the rind of the fruit.

"In places where wax is manufactured to any great extent the urushi is not made use of for its lacquer. As the trees are not cut for several years, they may be seen in the wax-producing districts growing to a height of

35 to 40 feet. In districts where the trees are used for their lacquer or varnish, they are cut every seven or ten years.

"The mode of obtaining wax from the urushi or lacquer tree is as follows:—

"Late in the autumn the branches, heavy with fruit, are lopped off and taken into the house. The fruit is pounded up in a pestle and then shaken in a basket-sieve so as to separate seed from rind. From this rind the wax is made. The mode of expressing it differs here and there, but in no very important particulars. The following brief description is taken from the mode as followed out in Sendai and Aidzu. Boiling water is got ready in an iron cauldron, over which a lattice-work of sticks is placed, and on these some matting. The sifted rinds of the fruit are then laid out on the matting and steamed, after which they are placed in hempen bags and again steamed. The bag, with its contents, is then put into a wooden trough, wooden wedges or blocks are inserted in the trough, and driven home on to the bag with heavy blows from a mallet. An aperture at the bottom of the trough provides for the egress of the wax. The trough and wedges are made of kiaki wood, and the mallets and blocks of wild mulberry—a very hard wood, and well suited to the purpose. A small quantity of oil, in the proportion of about one-tenth, is added to the wax to allow of its being expressed more easily. It then goes through another steaming process, and is again pounded in the trough.

"Wax from the yama-urushi, or wild lacquer tree, is obtained thus:—The fruit is collected at the latter end of summer, and is at once steamed without being pounded in a pestle as is the case with the urushi wax. The wax is purified by melting. A large tub of cold water is taken and placed under a wooden tank, having a small aperture close to the bottom. The melted wax is then poured into this tank, and escapes through the aperture into the tub beneath. While doing so it is stirred rapidly with the hand, after which it is placed either in matting or in shallow boxes, and dried in the open air for about fifteen days.

"The hage-urushi, from which wax is largely obtained, grows in the south-western portion of the island. This tree was first brought from the Loochoo Islands to Sakurajima, an island near Sakuma. Its production has so increased that there are now no less than seven different species, known as marumi, yasutomi, inotsume, ogawa, tanaka, fukiange, and matsu-yama, the last mentioned being regarded as the best. The hage-urushi tree is raised from seed or from slips. Koga wax is made from the fruit of the koga tree, which differs from the urushi and hage-urushi trees. It is an evergreen, and is largely grown in Otsugori, in the northern part of Nagato. It flowers in the middle of summer, the fruit ripening in autumn, when it is plucked and soaked in water for four or five days, after which it is trodden out with the feet, thus separating the outer rind. This is then dried and pressed, and the same course pursued as already described. The koga wax contains a large proportion of natural oil, which, in a measure, restricts its use to cold and temperate districts. Candles made of it show a very bright light, and if some contrivance could be hit upon for extracting the oil, the consumption of this wax would be increased, as it is very cheap compared with the other kinds. Refuse wax is used for manuring purposes.

"Bees' wax is obtained in this way: After the honey has been taken from the comb the latter is put into boiling water and allowed to simmer. It soon dissolves and floats to the surface. A wire network with raised sides is then inserted in the boiler and pressed down, thus causing the wax to rise through and above the net, the refuse part of the comb remaining at the bottom. The wax is taken out and placed in cold water, where it soon hardens. It is then lumped together and again melted, after which it is placed in moulds and is now ready for the market. The amount of wax obtainable from a comb is equal to about one-third of the weight. Wax is also made from the combs of insects, which build on the ibôta tree. This wax is of the purest white, and is prepared in the same way as bees' wax."

THE PHOSPHORESCENCE OF PHOSPHORUS, SULPHUR, AND ARSENIC.*

BY M. JOUBERT.

The theory of Berzelius, that the phosphorescence of phosphorus is due to the vaporization of the metalloïd, has been confuted by the experiments of Schrötter, but it has not entirely lost credit. The author confirms Schrötter's results. The phosphorescence does not take place in a vacuum, or in the absence of oxygen. It is well known that it is not apparent in oxygen gas at the ordinary temperature and pressure, but that it is necessary to raise the temperature or diminish the pressure in order to produce the phosphorescence. The author believes that there is also an inferior limit below which diminution of pressure causes the phosphorescence to disappear. He could not fix the limit, but its existence is indicated by the fact that when phosphorus is confined in nitrogen over water containing oxygen, the phosphorescence takes place in strata, occurring at regular intervals, although, of course, the oxygen is diffused from the water in a perfectly uniform manner. Though he is unable, also, to fix the superior limit at which increase of temperature causes a disappearance of the phosphorescence, his experiments indicate that it would be about 14°. The following are the tensions of phosphorus vapour at the different temperatures given. Glycerin was the only liquid which could be used in these experiments without being acted upon:—

Temperature .	5°	10°	20°	30°	40°	100°
Millimeters .	·03	·05	·11	·25	·48	3·44

When oxygen is mixed with an inert gas, such as nitrogen, and the lower limit of pressure is noted at which phosphorus placed in the mixture ceases to give any luminosity, the pressure exerted by the oxygen alone is below that which pure oxygen would exert. This difference is greater the larger the percentage of inert gas present. The property of phosphorus of giving rise to luminosity with a very small pressure of oxygen has enabled the author to ascertain that mercuric and silver oxides are appreciably decomposed at 100°. The temperatures at which sulphur and arsenic give a phosphorescent cloud are, for the first, about 100°, at the ordinary temperature, and a little higher for the second. Oxygen is necessary for the phenomenon, and there is a superior and inferior limit, as with phosphorus.

PREPARATION OF ABSOLUTE ALCOHOL.†

BY J. LAWRENCE SMITH.

This substance, as obtained in commerce, very seldom marks more than 98 to 99 per cent. It is, however, not unfrequently made in our laboratories, and when this is done the usual method is employed of pouring strong alcohol on lime until the lumps of lime are covered. This method of proceeding gives a thick magma which, when heated over a water-bath, allows the alcohol to pass over but slowly, and much of the alcohol is lost from the impossibility of the heat penetrating the thick mass. The method I follow differs from this in no way except in the quantity of lime employed; using the smallest quantity of lime necessary to abstract all the water, it is surprising how completely the lime will perform its function in this respect. Take, for instance, one litre of alcohol of 94 per cent.; this contains about 60 grammes of water; if to this be added 120 grammes of good and fresh-burnt lime, requiring about 40 grammes of water to convert it into

* *Journal of the Chemical Society*, from the 'Compt. rend.,' lxxviii., 1853.

† From the *American Chemist*.

hydrate, actual experiment proves that when kept in contact with the alcohol a sufficient length of time it accomplishes this absorption of water, and the alcohol decanted from the precipitated lime will be fully 98 per cent.

Operating upon this fact, I have been long in the habit of supplying myself with alcohol of 98 and 100 per cent. by proceeding in the following manner :—I have in my laboratory three or four 2-litre bottles, into each of which I place 1½ litres of 94 per cent. alcohol, the strongest alcohol sold in commerce ; to this is added 180 grms. of fresh-burnt lime, of the best quality, broken up into a coarse powder. These bottles are set aside on the shelf, and agitated from time to time : the oftener this is done the more rapid will the reaction be accomplished. A week or ten days will usually suffice, when the bottles are allowed to remain at rest, and the hydrate of lime will settle in a few days, and by a syphon two-thirds of the original alcohol can be drawn off free from lime, which marks 98 per cent. alcohol, and when filtered and 50 c.c.m. evaporated to dryness there will be left only the merest trace of lime, less than ½ milligramme. But, of course, re-distillation is so simple that if we wish the alcohol at 98° it can be readily distilled over a water-bath. The magma remaining in the bottle, when distilled over a water-bath, furnishes the remainder of the alcohol about one-half per cent. higher.

When absolute alcohol is desired, take the alcohol just as it has been syphoned off or distilled from the magma, put it in a convenient flask for distillation, and to each litre add 120 grms. of lime in coarse powder, attach to a Liebig condenser inverted, so that the alcohol will run back into the flask when condensed : this is continued for an hour and-a-half or two hours. The condenser is then placed in its normal condition, and alcohol distilled over which will mark 100 per cent. Recently I have learned that there is a method adopted of making the absolute alcohol by one distillation, operating by the inverted condenser first, but in this process the amount of lime called for is the usual quantity, whereas I find that by reducing the lime to its minimum, and always having bottles ready to furnish 98 per cent. alcohol, the operation is facilitated, and the loss diminished. So that with the ordinary conveniences and appliances of the laboratory, that are always at hand to be mounted, I can, with fifteen or twenty minutes of *personal attention and manipulation*, obtain a litre or two of absolute alcohol. Of course the time for the reaction of the materials and the distillation is not referred to, as this requires little or no supervision.

NOTE ON THE PROXIMATE ANALYSIS OF CINCHONA BARK.

*Limited to the Separation of the Four Alkaloids, Quinia, Quinidia, Cinchonia, and Cinchonidia, and the Three Acids, Quinic, Quinovic, and Quinotannic.**

BY ROBERT M. COTTON.

The process given below is nothing more or less than the combination of methods reported by different authorities, and given in Watts' 'Dictionary' and Gmelin's 'Handbook,' modified, in some particulars, after trial. The writer has found all the results of this process to be satisfactory. The same material was subjected to operations by other methods without obtaining as good results.

Any desired quantity—say one-half pound—of the powdered bark is macerated with warm water for two or three days and then percolated, water being added upon the percolator to exhaustion. Hydrochloric acid is added to the percolate, to a distinct acid reaction ; then solution of caustic soda is added, with stirring, to an alkaline reaction, and the mixture is set aside for some hours for subsidence of the precipitate. The whole is then filtered, and the precipitate well washed with cold water ; this precipitate, *a*, contains the alkaloids, and the filtrate, A, contains the acids.

The washed precipitate, *a*, is exhausted with (much) ether, giving an ether solution, *b*, containing the quinia and quinidia, while cinchonia and cinchonidia are left undissolved. Precipitate *a* is again washed with water, and then treated with 90 per cent. alcohol, which dissolves the cinchonidia with a little cinchonia : solution *c*. Precipitate *a*, washed again with water, remains as nearly pure cinchonia. The residue of solution *c* is the cinchonidia, with a little cinchonia. (Cinchonia is soluble in about 120 parts of 90 per cent. alcohol ; cinchonidia in about 12 parts of the same solvent.)

The quinia and quinidia of solution *b* are separated from each other by the unlike solubilities of their oxalates, as follows :—A moderately dilute water solution of oxalic acid is added to an acid reaction ; the ether is allowed to evaporate, or is distilled off ; and the residue is treated with water. The solution *d* contains the quinidia as oxalate, together with a very little oxalate of quinia. The residue is not soluble in water, is dissolved with dilute sulphuric acid, as acid sulphate of quinia, solution *e*. By precipitation with aqueous alkali, quinia is obtained from solution *e*, and quinidia from solution *d*.

Each of the four alkaloids may be obtained in crystals from a saturated alcoholic solution.

In the work for acids the quinovic acid is precipitated with normal lead acetate, leaving quinic acid in solution. Also, if the lead acetate is added short of saturation, the quinotannic acid remains in solution. To accomplish this result two-thirds of solution *a* is treated with neutral acetate of lead solution just to complete saturation, and immediately mixed with the remaining one-third. The precipitate of quinovate of lead is filtered out, washed with water, suspended in water, and decomposed by dropping in very dilute sulphuric acid, until the precipitate turns white, carefully avoiding an excess (which would decompose the quinovic acid). The liquid is decanted from the lead sulphate upon a filter, and the filtrate concentrated and left some time to crystallize as quinovic acid.

The filtrate from the precipitate by acetate of lead is concentrated to the consistence of a thin syrup, and set aside to crystallize. It may require the insertion of a nucleus for crystallization. There should now form a crystalline mass (quinic acid), mixed with yellowish drops of oily consistence (quinotannic acid). The mass is washed with ether, the residue being quinic acid, very deliquescent.

The ether solution is evaporated, leaving in residue the quinotannic acid, uncrystallizible.

* From the *American Journal of Pharmacy* for January.

A MODE OF DECOMPOSITION OF CHLORAL HYDRATE.*

BY M. TANRET.

If a mixture of solutions of chloral hydrate and potassium permanganate be made alkaline, say with caustic potash, gas is evolved, the liquid becomes discoloured, and sesquioxide of manganese is precipitated. If several grams of chloral hydrate be acted upon, and the temperature not raised above 40° C., the reaction will last for some hours ; then on filtering the liquid, the filtrate will be found to contain chloride, carbonate, and formate of potassium. The gas evolved is carbon monoxide. The reaction occurs equally with very dilute solutions, and even if borax be substituted for potash. This decomposition leads to a theory to account for the action of chloral hydrate upon the animal system. It is suggested that when this substance is taken into the circulation, it is submitted to oxidizing agencies ; the alkalinity of the serum determines its decomposition ; the carbon monoxide displaces the oxygen from the arterial blood, and produces an effect similar to that resulting from poisoning by carbon monoxide. The lowering of the temperature of the body and the prolonged action of the chloral hydrate, owing to slow decomposition, tend to make this theory more tenable than the assumption of its conversion into chloroform.

MORIBUND PHARMACIES.

SOMETHING more is due to the readers of this Journal than a bare record of the proceedings which on Monday last closed their third and final stage in a verdict of "death by misadventure." We refer to the coroner's inquiry respecting the circumstances which led to the death of CELINE MARIN, through the administration of corrosive sublimate in the stead of subnitrate of bismuth. The statements made in evidence, so far as they affect our present object, may be thus recapitulated. A young Frenchwoman who was suffering from diarrhœa requested a friend to fetch her some bismuth from a neighbouring pharmacy. The day was Sunday, and the shop was shut up; but the messenger was importunate, and gained admittance. The business, however, was one that was being carried on by trustees on behalf of the surviving representatives of a deceased chemist and druggist; the assistant placed in charge was absent, not being engaged to attend on Sundays; and the only person on the premises appears to have been a female housekeeper, who was not supposed to "serve in the shop beyond selling soaps and scents, and simple things of that kind." And there, in the gloom of a closed shop on a December day, this ignorant woman, in her wish to oblige an urgent customer, measured out a "spoonful" of bichloride of mercury instead of subnitrate of bismuth. The consequences to CELINE MARIN were a fortnight of suffering, terminated by death!

This sad accident should be pregnant with warning to all registered chemists and druggists who contemplate making provision for the carrying on of their business by trustees after their decease, under the provisions of the 16th section of the Pharmacy Act, 1868. It fully justifies also the views we have heretofore thought it right to urge upon this subject. For while on the one hand we have pointed out on several occasions the facility with which a sufficient trust may be created, and that consequently any hardship which may arise cannot fairly be attributed to the framers of the Act; we have, on the other hand, expressed a decided opinion that, except in very rare cases, it is advisable, even in the survivors' interest, that the trust should terminate at the earliest possible date, and the business be transferred to other hands whilst the prestige of the deceased proprietor is still associated with it. We are aware that this opinion has been criticized by those whose judgment we respect; but surely such a course is preferable to trusting to perfunctory services which result in the bismuth and perchloride of mercury bottles remaining undisturbed on the shelves for three months at a stretch. Moreover, if it becomes known that in such a case the trustees are responsible, to the same extent as the original proprietor would have been, for damages sustained through defective arrangements, it is probable that persons so nominated will be very chary of undertaking the duties.

But there is a broader phase of this question which demands the attention of chemists and druggists. One of the principal arguments which were urged to induce Parliament to legislate for the regulation of pharmacy in Great Britain, was the necessity for a personal qualification in persons who undertake the duties of dispensing medicines and selling poisons to the public. This principle received the endorsement of the Legislature in the Pharmacy Act, 1868; to a limited extent it is true, but still, to an unprecedented degree in the restriction of trade; and moreover, there are not wanting signs that public opinion is ripening for a further advance in the same direction. It is, therefore, not likely to be admitted by the public as consistent, that after claiming this *quasi*-professional standing, the same body of men should also claim the transmission of this personal right with no more limitation than in that of the goodwill of an ordinary business. We think there can be little doubt that the future credit with the public of the very proper restrictions which have received its sanction, is capable of being greatly damaged by an improper use of the rather elastic provisions of the 16th section of the Pharmacy Act, 1868.

This leads us to remark, that seeing the importance, in the interest of the public, of the Registrar under the Pharmacy Act receiving every assistance from public officials in enforcing its provisions, we regret that the Coroner, although aware of the fact of the name of the assistant not being on the Register of Chemists and Druggists for 1874, did not think it pertinent to the inquiry to ascertain how far the requirements of the Pharmacy Act had been complied with. Had he done so he would have found that no person bearing the name given by the assistant is a "qualified assistant" within the meaning of the Act; and the certificate produced was evidence of nothing more than that he *might* be a person who has become disqualified by being struck off the Register through neglecting to keep the Registrar informed of his proper address. Even in that case a reprimand from the Coroner would not have been wasted.

We would also respectfully protest against the view that because the woman was only allowed to sell harmless articles, her accident was one that might have happened to any of the tradesmen who formed the jury. In most shops the substitution of one article for another would only lead to temporary inconvenience; in this case the attempt to sell an innocuous substance from a stock including poisons resulted in death! On the whole, we think the occasion was one eminently fitted for emphasizing the fact that if trustees undertake to keep an "open shop for retailing, dispensing, or compounding poisons," they do it under the same responsibility as the former proprietor, and for impressing upon their consideration that they are bound to ensure that the business is throughout conducted under the qualified supervision required by the Pharmacy Act.

THE CHEMISTS' BALL.

On the evening of Wednesday last, the Annual Chemists' Ball was held at Willis's Rooms. The company numbered about three hundred. "Success to the Chemists' Ball," the only toast of the evening, was proposed at the supper table in a humorous speech by Mr. Alexander Bottle, of Dover, the Chairman of the evening.

M. Chevreul, the eminent French chemist, who is now eighty-eight years of age, has been promoted by Marshal MacMahon to the dignity of the Grand Cross of the Legion of Honour, in recognition of his services to science. The Marshal took the opportunity afforded by the reception on the *jour de l'an* to make the announcement to the *savant*.

Amongst the prizes which were awarded by the French Academy of Sciences at its sitting on the 28th December last, two fell to Assistant Professors of the Paris School of Pharmacy. These were a botanical prize of 500 francs, awarded to M. Joannes Chatin, for his monograph of the Valerianaceæ; and the Jecker prize (1872) to M. Jungfleisch, for his researches respecting the chlorinated benzols and the optical modifications of tartaric acid. M. Byasson was awarded 1,000 francs for his Memoirs on Chloral, which have appeared in this Journal. M. Lefranc, a pharmacien militaire, receives an award of 1,000 francs for his chemical and toxicological investigation of the *Atractylis gummifera*. M. Jules Lefort receives the Montyon prize of 2,000 francs for his 'Traité de Chimie hydrologique.'

We learn from the *Répertoire de Pharmacie* that in the scheme for the re-organization of the French army, it is provided that the corps of *pharmaciens militaires* shall consist of 1 inspector; 8 principals of the first class and 16 of the second; 40 majors of the first class and 55 of the second; 50 aides-majors of the first class and 15 of the second: in all 185 men.

Mr. F. M. Rimmington, F.C.S., Pharmaceutical Chemist, has been appointed Public Analyst for the borough of Dewsbury. Mr. Henry Meadows, of the University of Edinburgh, has been appointed Public Analyst for the borough of Leicester.

EXAMINATIONS IN LONDON.

January 20th, 1875.

Present: Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Hills, Linford, Martindale, Moss, Schweitzer, Taylor, and Umney.

Dr. Greenhow was also present, on behalf of the Privy Council.

MAJOR EXAMINATION.

Three candidates were examined. *All* failed.

MINOR EXAMINATION.

Sixteen candidates were examined. *Eight* failed. The following *Eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

	Moon, Murray James	Godalming.
	Blackwell, Josiah	St. Austell.
	Wiseman, Ebenezer Henry	Cambridge.
	Dixon, Henry Benjamin	Nottingham.
	Reade, Joseph George Edward	London.
Equal.	Davidson, Alexander	Insch.
Equal.	Mackaness, Charles	St. Neots.
	Pell, John	Market Harborough.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The following Certificates were received in lieu of the Society's Examination:—

Certificate of the College of Preceptors.

Buck, Anthony S. .... Liverpool.

Certificate of the Law Society of the United Kingdom.

Taylor, John .... Bolton.

Certificate of the Society of Apothecaries.

Dawson, Edward ....

Certificates of the University of Cambridge.

Bacon, Charles Henry .... Norwich.

Fry, Edwin Sargood .... Buckhurst Hill.

Certificate of the University of Oxford.

Adams, Benjamin .... Grantham.

PRELIMINARY EXAMINATION.

The following is the result of the Preliminary Examination held on the 4th inst.:—

ENGLAND AND WALES.

One hundred and fifty Candidates presented themselves for Examination, of whom *eighty-six* failed. The following *sixty-four* passed, and have been duly registered as Apprentices or Students:—

	*Anderson, Edward	Limber.
	*Holroyde, John	Halifax.
	*Thomas, Frederick William	Dowlais.
	*Wright, Robert	Buxton.
	*Woollons, Charles Henry	Ryde.
Equal.	*Rimmington, Harry	Epworth.
Equal.	*Senier, Alfred	London.
	James, Joseph	Plymouth.
Equal.	Holmes, James William	Norton.
Equal.	Senier, Harold	London.
Equal.	Williams, James	St. Clears.
	Hudson, Osborne Henderson	Sheffield.
	Pollington, Edward A. A.	Boston.
Equal.	Angior, Thomas Mathews	Bootle.
Equal.	Foot, Ernest George	Plymouth.

* Passed in the First Division.

Equal. { Sanders, John William Shanks ... Gorleston.
Southgate, Wilfred Burnham ... Hull.
Waites, Richard Foulstone ... Rotherham.
Whitwell, Alfred ... York.
Wildgoose, John Gratton ... Boston. }
Rogers, Stephen ... Manningtree.
Equal. { Gain, Alfred ... Shirley.
Grundy, George William ... Bolton.
Wilson, Alexander William ... Eastbourne. }
Goldstraw, Charles ... Bilston.
Equal. { Briggs, William ... Lancaster.
Dawson, Athol Stancliffe ... Sleaford.
Doe, James Emile ... Atherstone.
Marshall, Philip James ... Chesterfield.
Parker, Thomas Herbert ... Bedford. }
Equal. { Attfield, Walter ... Ashby Magna.
Benson, Henry Thomas ... Aberystwith.
Cock, Horace ... Attleborough.
Cox, Frederick E. W. ... Dudley.
Johnson, Richard ... Highfields.
Parry, Robert Henry ... Rhyl.
Sims, George Samuel ... Derby.
Walker, Robert ... Royston. }
Wilkinson, John ... London.
Brayne, John W. W. ... Newmills.
Equal. { Blenkiron, Jeremy ... Shildon.
Clare, John ... Reading.
Riddle, James Pearson ... South Shields.
Shrubshall, William Wyatt ... Tunbridge Wells. }
Lonnon, Alfred Imrie ... Stoke.
Millen, Herbert Alfred ... Peckham.
Equal. { Ball, Henry Simpson ... Nottingham.
Brook, Joe ... Lofthouse.
Codling, Arthur John ... Norwich.
Elton, Thomas Francis ... Cirencester.
Green, Thomas ... Hemel Hempstead.
Hadfield, Henry May ... Sheffield.
Jones, John ... Aberdare.
Lee, William Frederick ... Clifton.
Manduell, Thomas ... Hindpool.
Mansell, Charles ... Tewkesbury.
Nichols, Frederic Bulstrode ... Chelsea.
Perkin, Robert James ... Milford Haven.
Rickard, William Rees ... Holloway.
Rowland, John Llewellyn ... Carnarvon.
Shepperson, Wilson ... March.
Stretch, Joseph Harling ... Snaith.
Waddell, Andrew Morrison ... London.
Warren, Richard W. ... Leicester. }

SCOTLAND.

Twenty-two Candidates presented themselves for Examination, of these *nine* failed. The following *thirteen* passed and have been duly registered:—

*Clark, William ... Aberdeen.
*Michie, Robert ... Rhynie.
*Brown, John Jarvey ... Glasgow.
*Russell, James Lawson ... Edinburgh.
*Will, James ... Aberdeen.
*Alexander, Henry ... Aberdeen.
Equal. { Donaghey, John Joseph ... Dundee.
Thomson, John ... Edinburgh. }
Cochrane, William ... Dundee.
Maclean, James ... Jedburgh.
McDougall, Rea Ireland ... Edinburgh.
Ogilvie, William ... Balgaveny.
Morrison, William Norman ... Inverness.

The questions for examination were as follows:—

Time allowed: Three hours.

LATIN.

1. Translate into English:—Solis occasu suas copias Ariovistus, multis et illatis et acceptis vulneribus, in castra reduxit. Quum ex captivis quaereret Caesar, quam ob rem Ariovistus proelio non decertaret, hanc reperiebat causam; quod apud Germanos ea consuetudo esset, ut matres familiae eorum sortibus et vaticinationibus declararent, utrum proelium committi ex usu esset, necne; eas ita dicere, non esse fas Germanos superare, si ante novam lunam proelio contendissent.

2. Decline *rem*, *sortibus*.

3. Give the perfects and supines (active) of *quaereret*, *reperiebat*, *committi*, *contendissent*.

4. In what cases are *time when* and time *how long* put? Give examples.

5. Pater mihi et mater *mortui* sunt. Parse *mortui*.

ARITHMETIC.

6. Multiply £13. 12*s*. $11\frac{1}{4}$*d*. by $2\frac{7}{9}$.

7. Goods are bought at $6\frac{1}{2}$*d*. per pound, and the cost of carriage is $1\frac{1}{4}$*d*. per lb.; they are sold at £4. 10*s*. per cwt.; what is the gain or loss per cwt.?

8. Simplify $\dfrac{\frac{3}{4}}{\frac{5}{4}} + \dfrac{2\frac{1}{4} - \frac{3}{7}}{5\frac{1}{4} + \frac{1}{14}} - \dfrac{\cdot 2}{3\frac{4}{7}}$

9. Multiply 5·81 by ·4583, and divide 1·13 by ·000132.

10. Explain the *metrical* system of weights and measures. What is the weight in grammes of 10 litres of water?

ENGLISH.

11. In what different ways is the plural formed in English nouns? Mention any nouns that have no plural.

12. Into what classes may pronouns be divided? Give three examples of each class.

13. Write down the present and past tenses of the following perfect participles:—*bereft*, *borne*, *brought*, *caught*, *shorn*, *shrunk*, *sodden*, *swung*, *swollen*, *torn*.

14. Parse the following:—

O Solitude! where are the charms
That sages have seen in thy face?

15. Write a short account of the town that you know best.

The following is a list of the Centres at which the examinations were held, showing the number of Candidates examined at each Centre, and the result:—

Provincial Transactions.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSOCIATION.

Assistants' Section.

The fourth meeting of the session was held in the West Hall, Anderson's University, on Wednesday, the 6th inst. The President, Mr. John C. Hunter, in the chair. The Chairman introduced Mr. John M'Gill Murdoch, A.P.S., who read a very interesting paper "on the Pharmacy Act of 1868, its relation to Scotland, more especially Glasgow," in which he reviewed former Acts, as being the basis of the Act of 1868. Mr. Murdoch dwelt to some extent on the manner in which so many persons seemed to evade the principal section of the Act., viz., that of opening shop without being registered. Mr. Murdoch spoke of the necessity of something being done in this respect at once, as he thought if such a practice were allowed to continue the Act would be virtually a failure. A few remarks having been made by the chairman, and Messrs. Weir and Nance, Mr. Murdoch was awarded a hearty vote of thanks for his interesting paper. The Secretary intimated that owing to the annual festival taking place on the 3rd of February, the next meeting would be held on Wednesday, 27th January, when Mr. J. J. Weir would read a paper on the "Laughing Animal."

The third meeting of the session was held on Wednesday, the 9th December, 1874, when Mr. Robert Taylor read an excellent paper on "Water."

MANCHESTER CHEMISTS' AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

At an ordinary meeting of the above Association, held at their rooms on Wednesday evening, January 13th, Mr. E. G. Hughes in the chair, Mr. Louis Siebold, F.C.S., delivered the third of his series of lectures on the analysis of common articles of food and drink. There was a good attendance. The lecturer stated that milk commonly gave an acid reaction with litmus, due to the presence of carbonic acid. If boiled it became neutral. Sometimes it was possible to obtain indication of both acid and alkaline reactions with the same sample, the latter being produced by the action of the alkaline phosphates present. Samples of urine were occasionally met with possessing both acid and alkaline properties; such specimens contained traces of acid urates and carbonate of ammonia. It was a remarkable fact that it is possible to have an exceedingly dilute solution of an acid and alkali which shall for a time give *both* reactions with litmus. In such cases it seemed that the molecules of acid and alkali could exist in solution in a state of mutual indifference to each other. Starch and farinaceous matter might very easily be overlooked in milk if only a small quantity of tincture of iodine be used as a test. Sufficient iodine must be added to produce a decided yellow colour, as a considerable quantity enters into combination with the mineral constituents of the milk, and the sample remains colourless until the excess of iodine produces the blue colouration with starch. Chalk and other mineral powders might be detected by mixing a sample of the milk with an equal volume of water, twice its volume of ether, and a little solution of potash, and well shaking in a test-tube. The ether dissolves out the fat, and separates in a clear stratum; the aqueous solution of casein, etc., beneath should be only slightly opaque.

The sp. gr. of milk should be from 1·029 to 1·034. Every 10 per cent. of water added reduces the third decimal by 3, but specific gravity must not be regarded as a very reliable indication of the purity of milk; for as the density is increased by the casein, sugar of milk, and soluble salts, and diminished by the cream, it follows that when some of the latter is removed and water added the normal specific gravity is maintained. If applied at all, it should be after the milk has stood long enough to throw up its cream. Its density, after removing the cream, should not fall below 1·029, or it is probably adulterated with water.

Different samples of milk yield very varying proportions of cream, and some throw it to the surface much more rapidly than others. When mixed with water milk gives up its cream quicker than when pure.

Nothing less than a quantitative analysis of milk is satisfactory, but this does not present much difficulty. Professor Wanklyn's little book on milk analysis may be taken as a guide.

Average milk contains $12\frac{1}{2}$ per cent. of solids and $87\frac{1}{2}$ per cent. of water; no milk should contain less than 11·8 per cent. of solids, that is of fat, sugar of milk, casein, and mineral salts; of this about 3 to $4\frac{1}{2}$ per cent. is fat, 4 to 5 per cent. casein, 4 to 5 per cent. sugar of milk, and ·7 to ·8 per cent. mineral salts. Human milk contains about one-sixth the amount of mineral salts found in cows' milk. Professor Wanklyn says that the amount of solids not fat is constant in pure milk, and on this fact his mode of testing is based. Five cubic centimetres of milk are heated in a platinum dish or a water bath for three or four hours, or till the residue ceases to lose weight; this gives the *total solids* present. Formerly it was considered necessary to heat to 110° C. If this is done a further loss of weight occurs, probably from the evaporation of a little water entangled amongst the fat; but Professor Wanklyn considers the temperature of boiling water sufficient, and states that his results will always bear comparison with each other.

The total solids are then treated with boiling ether and repeatedly washed on a filter with the same liquid, until 50 c.c. has passed through. This evaporated in a water bath yields the fat, and the residue on the filter the *total solids not fat*, of which not less than 9·6 grammes should be obtained from 100 c.c. of pure milk. The proportion of water used as an adulterant is easily calculated when the amount of solids not fat is known. Treat the residue with alcohol and boiling water to dissolve out the sugar of milk and soluble salts; casein and insoluble salts remain on the filter; dry on a water-bath; weigh and burn off the casein; the remainder consists of the insoluble salts. Evaporate the liquid which has passed through the filter and we obtain the sugar of milk and soluble salts. Weigh, burn off the sugar of milk in a crucible, and the soluble salts remain.

Some chemists add a weighed quantity of powdered glass or sulphate of barium to the milk before evaporation in the platinum dish. This addition greatly facilitates the evaporation of the water; the residue thus obtained is very easily exhausted with hot ether if packed in the barrel of a small male syringe plugged with cotton wool. He (the lecturer) did not know why Mr. Wanklyn objected to this addition.

Mr. Siebold then described and illustrated Horsley's method of estimating volumetrically the value of milk, which, though less accurate than Wanklyn's, was exceedingly handy.*

Mr. Benger inquired whether there would be any objection to contracting the tube used by Horsley at the point where the percentage of fat was read off, so that greater accuracy might be obtained. Should this interfere with the necessary shaking of the mixture it might be transferred to a second narrow graduated tube after agitation in the wider one.

Mr. Siebold said a similar modification of the apparatus had suggested itself to him, and he had indeed used a narrow Mohr's burette for the purpose.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 14th January, 1875, Professor Odling, F.R.S., President, in the chair. After the usual business of the Society, a paper "On the Action of Organic Acids and their Anhydrides on the Natural Alkaloids," part III., by

* See *Pharm. Journ.*, 3rd series, vol. 5, p. 188.

Mr. G. H. Beckett and Dr. C. R. A. Wright, was read by the latter. It is a continuation of their researches on the opium alkaloids, morphine and codeine. The next communication was a "Note on the Effect of Passing the Mixed Vapours of Carbon Bisulphide and Alcohol over Red Hot Copper," by Mr. T. Carnelley. Dr. Armstrong then read a paper "On the Iodonitrophenols." The meeting was finally adjourned until Thursday, 4 February.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture II.

The Alcohol Group of Organic Bodies—Actions of different Alcohols.

If before a chemist of a hundred years ago you could have placed a specimen of spirit of wine or alcohol, and could have asked him of what it was composed, he would have told you that it was the element of water combined with elementary fire, to which elementary fire he would give the name of phlogiston, a name derived from a Greek word, signifying to burn or inflame. He would tell you that all bodies that burned were phlogisticated, and that bodies that would not burn were dephlogisticated. The substance that was left behind was, he would probably add, the element with which the elementary fire had previously been combined. Were you to ask him whence he derived this knowledge, he would say, "from the greatest chemist who had ever lived before his time, George Ernest Stahl, Professor of Medicine, Anatomy, and Chemistry in the University of Halle, who had died in Berlin, whither he had gone to be physician to the King of Prussia—forty years ago."

As proof that alcohol was elementary water combined with phlogiston, our ancient chemist would probably show you this experiment:—He would place a portion of the spirit in a cup, would set fire to the spirit, and would invert over the fire a glass vessel, shaped almost like a common globe, which he would call a cucurbit, into which he would allow the flame to ascend. He would indicate that within the glass vessel a vapour, derived from the burning fluid, formed and condensed, as you see it forming and condensing now. Collecting this fluid, he would prove to you that it was water, which water he could prove to be nothing else but one indivisible thing, therefore an element. Thus his demonstration would be complete. The element, while it existed as spirit, yielded fire on burning; it was fire water. The fire was condensed with the water; nothing could be plainer, according to his light of science.

If you had inquired of the chemist whether he had any symbol by which to denote elementary water or spirit he would give you, as a symbol for water, a sign something like the letter **V**, with two wavy lines following the letters; and for spirit of wine, a sign like the letter **V** with the letter **S** in the centre, as I put it on the black board; and if once more you questioned him as to whether his laboratory contained any similar chemical substance he would answer—none. Spirit of wine stood by itself, a pure substance, possessing single and special virtues.

If, passing over the intervening hundred years, you asked the chemist of to-day, "What is alcohol?" he would tell you that it was an organic radical called ethyl, combined with the elements of water. He would explain that water was no longer considered to be an element, but to be composed of two elements, called hydrogen and oxygen, two equivalents of hydrogen being combined in it with one equivalent of oxygen. He would inform you that the radical he had called ethyl was a compound of carbon and hydrogen, and he would add that this radical in alcohol took the place of one of the equivalents of hydrogen of water. He thereupon would give you a symbol for water and alcohol, but symbols of a very different kind to those presented by his learned predecessor. He would express the names of the elements composing the water and spirit by the first letters of their names, and add their equivalents, or parts, by figures attached to the letters. Thus his symbol for water would be H_2O; for the radical ethyl, C_2H_5; and for alcohol (C_2H_5) HO, or C_2H_6O.

Were you interested about the theory of phlogiston, invented by the illustrious George Ernest Stahl, your modern guide would instruct you that the theory had long since been discarded, and that towards the latter part of the last century the very books of its discoverer had been burned in derision by a priestess of science in one of the temples of science in Paris. Then through what a wonderful history of discovery during the hundred years he would, if he liked, lead you. Into this cucurbit in which I burned the alcohol, and which you will observe I closed by placing it with its mouth downwards upon the table, he would pour clear lime water as I do now; he would shake the water round the sides of the cucurbit and see, as he did it, the water would become milky white. This phenomenon he would indicate was due to the presence of a gas which the old chemist had actually collected but had overlooked. That gas is carbonic acid. It, as well as the water, was the product of the combustion of the spirit, and it now, in combination with the lime water, has united with the lime, forming carbonate of lime or chalk. Following the history of this gas, called once fixed air, because it could thus be fixed by lime and other substances, he would show how it had been proved to consist of carbon and oxygen; how it is given off from the burning of bodies containing carbon; and how a French chemist of the last century, named Lavoisier, traced out by analysis how, in fermentation, the juice of grapes is changed from being sweet and full of sugar into a vinous liquor, which no longer contained any sugar, the inflammable liquor known as spirit of wine. Thence it would be shown that the same illustrious chemist, making an analysis of sugar and studying the effects of yeast in causing fermentation of sugar, collected and weighed the elements produced, determined the elementary composition of spirit as consisting of carbon, hydrogen, and oxygen, and from his research announced the new principle in chemistry, that in all the operations in art and nature nothing is created; that an equal quantity of matter exists both before and after the experiment; that the quality and quantity of the elements remain precisely the same; that nothing takes place beyond changes and modifications in the combinations of the elements; and that in every chemical experiment an exact equality must be supposed between the elements of the body examined and those of the products of its analysis. Finally, on this head, he would state the theory of Lavoisier, that *must* consists of alcohol combined with carbonic acid, and that the effects of vinous fermentation upon sugar are reduced to the mere separation of the elements of sugar into two portions; one portion oxygenated at the expense of the other, so as to form carbonic acid; the other disoxygenated to form alcohol. So that were it possible to reunite alcohol and carbonic acid the product would be sugar. Bringing you down to a later period, the modern chemist would describe a theory current about between thirty and forty years ago, that alcohol is a compound of olefiant gas and water, and that in a state of vapour it consists of equal volumes of these. Or, again, that it was a hydrate of ether; or, again, according to a still later view, that it was a hydrated oxyde of ethyl. Thus he would bring you to the latest theory as to composition which I have already supplied.

Lastly, if for the sake of further comparison you asked the chemist of to-day whether alcohol had any ally or

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts*.

congener, he would reply, many. He would give you, for instance, this spirit, which he would call methylic alcohol, and which he would tell you was got also by distillation, only that the distillation was dry, and that the substance distilled was wood; or he would give you this specimen, which he would call amylic alcohol, and which he would tell you was got by distillation, not of wood, but of potato. Again he would show you other specimens, to which he would give different names, as indicated in the following table:—

TABLE I.—ALCOHOLS.

	Elementary composition.		
Methylic, Protylic (wood spirit) . . .	C	H_3	HO
Ethylic, Deutylic (common alcohol) . .	C_2	H_5	HO
Propylic, Tritylic	C_3	H_7	HO
Butylic, Tetrylic	C_4	H_9	HO
Amylic, Pentylic (potato spirit, fusil oil)	C_5	H_{11}	HO
Hexylic	C_6	H_{13}	HO
Hextylic, Œnanthic	C_7	H_{15}	HO
Octylic	C_8	H_{17}	HO
Decatylic	C_{10}	H_{21}	HO
Cetylic	C_{16}	H_{33}	HO
Melylic	C_{30}	H_{61}	HO

Directing your attention to the composition of these alcohols, the chemist would beg you to observe that their chemical construction is throughout the same, that is to say, in all cases, a radical composed of carbon and hydrogen has replaced one of the equivalents of hydrogen of water. The radicals, however, vary in respect to the equivalents of the elements of which they are composed, and to distinguish them they have different names. Essentially each radical, though it is composed of more than one element, acts as if it were one, and is called a base, because it is a root or origin upon which other structures rest. Thus, in the present case, the radicals, as they vary in amount of carbon and hydrogen which they contain, produce, in each case of their combination with water, an alcohol possessing a different property or different properties from the other alcohols. The table No. II. illustrates the increase of carbon or hydrogen in the radicals of the series.

TABLE II.—RADICALS OF ALCOHOLS.

Composition.		Old Name.	New Name.
C	H_3	Methyl	Prolylen.
C_2	H_5	Ethyl	Deutylen.
C_3	H_7	Propyl	Tritylen.
C_4	H_9	Butyl	Tetrylen.
C_5	H_{11}	Amyl	Pentylen.
C_6	H_{13}	Hexyl	Hexylen.
C_7	H_{15}	Heptyl	Heptylen.
C_8	H_{17}	Octyl	Octylen.
C_{10}	H_{21}	Decatyl	—
C_{16}	H_{33}	Cetyl	—
C_{30}	H_{61}	Melyl	—

In the first of these radicals, methyl, you will see that the radical is composed of one of carbon and three of hydrogen. The radical ethyl of two of carbon and five of hydrogen. The radical propyl of three of carbon and seven of hydrogen, and so on, the increase in the equivalents of the elements being after a given rule in the whole series, the carbon increasing one, and the hydrogen two with each progressive step. So, as the alcohols progressively change from the first of the series, the methylic, they grow richer in carbon and hydrogen, and proportionately, they grow heavier, less soluble, and less volatile.

A very simple experiment suffices to show the increase of carbon in these series. If I take a piece of cotton wool, place it in a glass cup, pour upon it a little methylic alcohol (in which alcohol you will notice from the table there is the smallest amount of carbon), set fire to it and hold a white plate over the flame, the plate remains white because the air that reaches the flame is sufficient to consume all the carbon. If I do the same experiment with ethylic alcohol, although the carbon is a little greater, yet the result remains the same. If I move two steps higher, viz., to butylic alcohol, in which there are four equivalents of carbon, the combustion is not quite complete, and therefore a shade or stain of carbon is left on the plate; and if, going one step further in the series, I use amylic alcohol, then the combustion is rendered so imperfect that a thick layer of carbon, derived from the alcohol, in the destruction of it by the burning, is left upon the white surface.

I may digress here for a moment to state—if the practical fact about to be told be considered a digression—that this simple mode of testing common alcohol will serve roughly to detect adulteration of it with the heavier alcohol—fusil oil. This heavier alcohol is used in adulteration, and as you will learn when you hear of its effects, it is a dangerous adulterant. I was dining a few months ago with some friends, one of whom produced a small flask of precious liquor he had had presented to him, and which was said to be an unusually choice hollands. On examining it I felt sure it was a gin treated with fusil oil, and on burning a little of it, this suspicion was confirmed by a deposit of carbon upon a white dish. I warned my friends forthwith of the danger of drinking this heavy, though certainly pleasant spirit, and the majority took the warning. Two, less prudent, indulged, to suffer for the next two or three succeeding days to an extent that convinced them there was no mistake in the scientific and friendly admonition they had received.

The physical distinctions between the various alcohols now before us are marked by other signs. For example, as we move from the methylic alcohol upwards, we discover that their vapours increase in weight, that as fluids they grow heavier, and that their boiling point, that is to say the temperature required to make them boil, has to be increased. In Table No. III. these facts are presented in relation to the four alcohols of the series:—

TABLE III.—ALCOHOLS.

NAME.		Chemical comp.	Vapour density.	Specific gravity.	Boiling Point.	
Old	New		$H_2 = 1$	Water 1,000	Cen.	Fah.
Methylic..	Protylic..	CH_4O	16	814	60	140
Ethylic ..	Deutylic..	C_2H_6O	23	792	78	172
Butylic ..	Tetrylic ..	$C_4H_{10}O$	37	803	110	230
Amylic ..	Pentylic..	$C_5H_{12}O$	44	811	132	270

Thus you will see that the vapour density of methylic alcohol is 16 when compared with hydrogen gas as a standard; of ethylic alcohol, 23; of butylic, 37; and of amylic, 44. In respect to the specific gravity of the fluids, that is to say of the weights of the fluids themselves, compared with water reckoned as a thousand, the same rule extends, with the one remarkable exception, viz., that the methylic alcohol appears heavier than the ethylic, after which the weights increase, so that amylic alcohol stands as 811 to 792, the weight of ethylic. Again, as to the boiling points, the lightest alcohol boils at 140, that is 72° below the boiling point of water; ethylic at 172; propylic at 205; butylic at 230, or 18° above the boiling point of water; and amylic at 270, or 58° above the boiling point of water, on Fahrenheit's scale.

The analogies between these various alcohols are sustained throughout by other chemical changes relating to them. If we expose diluted common alcohol to the atmosphere under fitting conditions it becomes acidified; in other words, it is converted into vinegar. This is due to its oxidation, in which process there are two steps, one by which the spirit is converted into a substance called aldehyde (dehydrated alcohol—al-de-hyd), and then into acetic acid, or vinegar. In the formation of the aldehyde two atoms of the hydrogen are oxidized, by which water is produced, and the aldehyde has therefore the composition of C_2H_4O. In the formation of the acetic acid another atom of oxygen is added and the acetic acid has therefore the composition of $C_2H_4O_2$. This same series of changes extends through all the alcohols, as will be seen from the next table.

TABLE IV.

Alcohols.	Aldehydes.	Acids.
Mythylic ....CH_4O	Formaldehyde CH_2O	Formic ......CH_2O_2
Ethylic ....C_2H_6O	Aldehyde.... C_2H_4O	Acetic...... $C_2H_4O_2$
Propylic ....C_3H_8O	Propionaldehyde ......C_3H_6O	Propionic .. $C_3H_6O_2$
Butylic ....$C_4H_{10}O$	ButylaldehydeC_4H_8O	Butyric .... $C_4H_8O_2$
Amylic ....$C_5H_{12}O$	Valeraldehyde$C_5H_{10}O$	Valerianic.. $C_5H_{10}O_2$

I said, in the first lecture, that from common or ethylic alcohol a new compound can be obtained by heating it with sulphuric acid, to which compound the name of ether is applied. In like manner, an ether can be obtained from the other alcohols.

TABLE V.—ETHERS.

Name.	Composition.	Form.	Boiling Point.
Methyl..........	C_2H_6O	Gas	..
Ethyl	$C_4H_{10}O$	Fluid	94°Fah.
Propyl	$C_6H_{14}O$	"	153°Fah.
Butyl	$C_8H_{18}O$	"	219°Fah.
Amyl	$C_{10}H_{22}O$	"	348°Fah.

If chlorine be brought to bear upon ethylic alcohol the elements of water are removed—that is to say, the oxygen and the hydrogen—and are replaced by chlorine, and there is formed chloride of ethyl. This change can be extended to all the other alcohols, the properties of the products being modified by the base, as will be seen by reference to the tables subjoined.

TABLE VI.—CHLORIDES.

NAME.		Chemical comp.	Vapour density.	Specific gravity.	Boiling Point.	
Old.	New.		$H_2=1.$	Water 1,000	Cen	Fah.
Methyl..	Protyl....	$C H_3 Cl$	25	Gas	..	..
Ethyl ..	Deutyl ..	$C_2 H_5 Cl$	32	921	11	52
Butyl ..	Tetryl....	$C_4 H_9 Cl$	46	880	70	158
Amyl ..	Pentyl ..	$C_5 H_{11} Cl$	53	..	102	216

The same rule extends to the action of iodine on the alcohols, as is shown in the next table:—

TABLE VII.—IODIDES.

NAME.		Chemical comp.	Vapour density.	Specific gravity.	Boiling Point.		Per cent. of Iodine.
Old.	New.		$H_2 = 1$	Water 1,000	Cen.	Fah.	
Methyl	Protyl.	$C H_3 I$	71	2240	42	108	89·4
Ethyl..	Deutyl	$C_2 H_5 I$	78	1946	72	162	81·4
Butyl..	Tetryl.	$C_4 H_6 I$	92	1604	120	248	69 0
Amyl..	Pentyl.	$C_5 H I$	99	1511	146	295	64·1

Once more the rule extends to the action of nitrous acid, as indicated in the following:—

TABLE VIII.—NITRITES.

NAME.		Chemical comp.	Vapour density.	Specific gravity.	Boiling Point.	
Old.	New.		$H_2=1$	Water 1,000	Cen.	Fah.
Methyl ..	Protyl....	$CH_3 NO_2$	30	..	Gas.	Gas
Ethyl	Deutyl ..	$C_2H_5NO_2$	37	0·917	18	64
Butyl	Tetryl....	$C_4H_9NO_2$	51	..	64	147
Amyl	Pentyl ..	$C_5H_{11}NO_2$	58	0·877	96	205

These illustrations could be largely extended, but they are sufficient for our purpose. I have brought, for those who are curious to see them, twelve specimens of these different compounds formed on the alcohols. Six of these belong to the ethyl, or common alcohol series, six to the amyl, and they include respectively specimens of the alcohols, of the acids of the alcohols, of the ethers, of the chlorides, of the iodides, and of the nitrites. One of these specimens, I mean the nitrite of amyl, has within these last few years obtained a remarkable importance owing to its extraordinary action upon the body. A distinguished chemist, Professor Guthrie, while distilling over nitrite of amyl from amylic alcohol, observed that the vapour, when inhaled, quickened his circulation, and made him feel as if he had been running. There was flushing of his face, rapid action of his heart, and breathlessness. In 1861-2, I made a careful and prolonged study of the action of this singular body, and discovered that it produced its effect by causing an extreme relaxation, first of the blood vessels, and afterwards of the muscular fibres of the body. To such an extent did this agent thus relax, I found it would even overcome the tetanic spasm produced by strychnia, and having thus discovered its action, I ventured to propose its use for removing the spasm in some of the extremest spasmodic diseases. The results have more than realised my expectations. Under the influence of this agent, one of the most agonising of known human maladies, called angina pectoris, has been brought under such control that the paroxysms have been regularly prevented, and in one instance, at least, altogether removed. Even tetanus, or lock-jaw, has been subdued by it, and in two instances, of an extreme kind, so effectively as to warrant the credit of what may be truly called a cure. I notice this action of nitrite of amyl because it will be referred to again in explanation of certain of the effects of alcohol.

I should have liked, if there had been time, to have dwelt at greater length on many other interesting points bearing on these different alcohols and their derivatives. I should have been pleased to have presented to you a more extended account of the progress of discovery during the past century leading to these modern facts; and I should much have liked to have rendered more complete the description of the alcohol series of bodies, by explaining the differences of what are called monatomic, diatomic, and triatomic alcohols; but I must desist for two reasons, first, because the study would lead me into too great detail, and secondly, because it would introduce to notice a series of compounds, the physiological action of which are not so well understood as are those to which I shall soon direct your attention, and the study of which is more than enough for the time that is at our disposal. It must be considered sufficient, therefore, if I have succeeded in showing that the common alcohol is but one of a group of a series of chemical compounds, and that its superior claim to our notice rests upon its antiquity as a discovered substance, and on its enormous distribution in civilized communities, rather than on its special or distinctive properties as a chemical agent.

One other series of facts I would, however, briefly describe before leaving this part of my subject. If into this ethylic alcohol I throw a portion of the metal sodium a brisk action immediately begins to take place; as you will see, a gas escapes, which I easily collect in a glass tube, which burns, and if mixed with air, explodes, as you hear. The gas is hydrogen. A change or substitution has occurred in this experiment. The hydrogen belonging to the water of the alcohol has been replaced by the metal, and what is called sodium alcohol has been formed. If potassium had been used, the result would have been similar.

By acting on common alcohol with strong potash, then with sulphuretted hydrogen, and afterwards with iodide of ethyl, a new alcohol is produced called mercaptan. In this fluid the oxygen of the alcohol is replaced by sulphur, so that the formula for it is (C_2H_5) HS. It is a fluid, whitish in colour, and of so offensive and penetrating an odour that it can hardly be approached until it is largely diluted with common alcohol. It is nearly insoluble in water, but imparts to it its peculiar odour: its specific gravity is 832, compared with water as 1000; it is thirty-one times heavier than hydrogen, and it boils at 135° Fahrenheit.

Sulphur alcohol is very rarely seen, but there is a diluted specimen here which has been prepared with very great care. There is only five per cent. of it in the solution, and yet its odour is as much as can well be borne.

From this point I proceed to dwell on the action of certain of the alcohols which have been brought before us up to the present time, excluding on this occasion the alcohol best known, I mean the common alcohol of commerce, or, as we now know it chemically, ethylic alcohol. The point I shall aim at will be to show the influence of these alcohols upon animal life, and thereby to lead up to the action of ethylic alcohol pure and simple. The subject is one entirely new, and is limited to a very few bodies of the alcohol group, viz., to methylic alcohol, butylic, amylic, the potassium and sodium alcohols, and sulphur alcohol or mercaptan.

(*To be continued.*)

Parliamentary and Law Proceedings.

The Prosecution of a Chemist and Druggist for Selling "Morning Tonic."

At the Hull Police Court, on Friday the 15th inst., the adjourned summons, charging Wm. Staning, chemist, Cogan-street, with retailing spirits, to wit, a compound called "pick-me-up," or "morning tonic," on the 1st of October, without having a license for the sale of exciseable liquors, was heard before the police magistrate (T. H. Travis, Esq.).

Mr. F. Summers again represented the Excise Authorities, by whom the information was laid, and Dr. Rollit, representing the Hull Chemists' Association, appeared for the defendant.

Dr. Rollit briefly stated the points of defence, which were, that the "morning tonic" was a tincture or medical preparation having curative properties, that it was sold as a medicine, and that the directions on the bottle, as to dose, were capable of explanation, and in short, that the compound was such as a physician might prescribe, and a chemist dispense from the former's prescription. He then called—

Walter Staning, who said: I am the son of and assistant to the defendant. I have passed the necessary examinations to qualify myself for a chemist's assistant. I have on one or two occasions made the morning tonic sold by the defendant. It was made in a quantity of about four gallons at a time. [The witness was asked several questions about some of the tonic being made shortly before the 1st of October, but it appeared that he did not remember any being made in September, and he left home for a time at the latter part of the month.] It was not sold until three weeks or a month after it had been made. It was not in a fit state, medicinally, to be sold until after the lapse of that period. There was some tonic in stock on or about the 1st of October, but he did not know when it was made. The tonic was sold in bottles at 1*s.*, 2*s.* 6*d.*, and 3*s.* 6*d.*, as required. If a person wanted a shilling's worth it would be given him from the bulk. It was kept in a room at the back of the premises in a carboy. The quantity sold might average a shilling's worth per day. The average quantity of spirit purchased by the defendant per annum for purposes of business was about twenty-one gallons. During the three or four months that I was at home about six gallons of spirit were used, or were in stock in the shape of tinctures.

Dr. Rollit: Now, will you tell the Court the class of bottles you were in the habit of using. I don't mean of that tonic only, but generally?—We use ordinary medicine bottles.

Do you use any other sort?—We use any kind of bottles we can get hold of.

Do you use many bottles of this sort (holding up that in which the tonic was sold, a disused hock bottle)?—We do, for economy's sake. We use them for oils, cattle medicines, the tonic, etc. For smaller quantities of the tonic medicine bottles were generally used, but for the larger quantity usually a round bottle like the one in question. The price of the medicine bottle would be about 3*d.*, and the one produced ½*d.* or 1*d.* The trade used all kinds of bottles.

Are bottles like this one used in the trade?—Yes, often. No difference was made in selling the tonic to the custom in selling other things. It had been sold like all other medicines in the shop. Since I have been with my father the tonic has, so far as I know, been made with the same ingredients.

Will you tell us the quantities of the ingredients used?

Mr. Travis (smiling): You will lose your trade if you do. Let us first get the ingredients.

Witness: Gentian, coriander seeds, cascarilla, chiretta, orange peel, cayenne pepper, calumba root, raisins, quassia, cardamoms, chamomile, cochineal, cinnamon, nutmegs, spirit, and water. Proof spirit was used. Proof spirit, as we know it, is "half and half"—half spirit and half water. Rectified spirit is alcohol, with a certain percentage of water.

Now, will you tell me, please, the medicinal properties of each of these compounds?—Gentian is a bitter; quassia is a bitter; cardamom, an aromatic bitter; calumba, a bitter; chamomile is a stomachic; cascarilla is a tonic; and coriander—that is a stomachic. I do not know that there has been any difference in the way the tonic has been made.

The witness was asked to taste the tonic that had been sold, and having done so he said: The tonic produced is the same as that dispensed by me in September, and on all occasions, so far as I know.

By Mr. Summers: I have been in the habit of manufacturing this tonic for about six years.

Have you advertised it?—When first we made it we did so, and we gave it up because we did not wish to push the sale of the tonic as the profit upon it was only small.

Did your father get a certain class of customers for it?—We had no regular class.

Did you sell the largest quantity of the 3*s.* 6*d.*, the 2*s.* 6*d.*, or the 1*s.* bottles?—The 3*s.* 6*d.* bottles.

Then your customers liked to have a good lot of it?—It is cheaper.

Now, the gentian, quassia, and calumba root, are they not bitters, pure and simple?—Yes.

And the coriander, nutmegs, cayenne pepper, orange peel, they are condiments?—Yes, but they are also tonics of a kind.

Are they not more of a flavouring quality?—Yes.

And the chamomile flower, is a stimulant?—It is a stomachic.

Now, all the ingredients you have mentioned, are they not used in the manufacture of bitters?—I am sure I don't know; I have never made any bitters.

Have you not studied the component parts of the manufacture of British bitters?—No.

Now, gentian, calumba, chiretta, coriander, and nutmegs, are they not found in bitters?—They are tonic bitters.

Mr. Summers then drew the witness' attention to the directions on the bottle :—" A small wineglassful may be taken at any time ; when mixed with a little sherry it forms a milder and very agreeable tonic."

Mr. Travis said he had not noticed the mention of the sherry on the last occasion.

Dr. Walton, who was here appealed to by the stipendiary, said a small wine glass would hold about an ounce.

Re-examined by Dr. Rollit, witness again described the character of the drugs used, and said they were aromatic, carminative, and tonic.

In reply to Mr. Travis, witness said : If any one asked me for a " pick-me-up," I should give a little tincture of gentian, and a little orange water.

Mr. Travis : Then, what do you call this ?—A morning tonic.

Mr. Travis : Your father knew what "pick-me-up" was. When any one asked you for a bottle of "pick-me-up," you would give him this medicine ?—Yes, because it is the name given it by the public. If any one asked me for a " pick-me-up," I should give him a draught there and then, but if I were asked for a bottle, I should give him the " morning tonic."

Mr. William Hunt: I am editor of the *Eastern Morning News*. I have been in the habit of using this tonic. It has curative properties, or I should not have continued the use of it; I have used it occasionally for six years. I have never taken it as a beverage, but as a medicine. It is too bitter to be taken as a beverage. Other persons in my house have taken it with advantage besides myself.

Mr. Summers: I ask you, Mr. Hunt, is it not very nice ?—It is a very good tonic.

Doesn't it warm the stomach ?—So do many other nastier things. It is bitter in the mouth.

Which will leave you in five minutes ?—I don't know.

Supposing it is diluted, won't it make it more agreeable still ?—Yes, if you followed the directions, and diluted it with sherry. It was less bitter in water.

Were you aware of the large quantity of spirit this tonic contained ?—I never noticed it.

Nearly 70 per cent. of proof spirit ?—I know nothing about it.

By Dr. Rollit: The tonic is decidedly bitter ; I have tasted bitterer things.

Mr. Travis : Is it not a thing persons use who habitually take spirits ?—I have but slight experience.

Dr. Gibson, a medical man, of thirty-five years' practice, was the next witness. He said : I have just tasted the " tonic." I could detect potass and quassia from its excessive bitterness. There was also gentian, and I believe I can taste chamomile. The taste, the colour, and the mixture generally with the presence of the various ingredients that had been named. Assuming that it was made of proof spirit he should describe it as a stimulant and tonic.

I ask you as a medical man, is it such a mixture as you would prescribe under certain circumstances ? — No, I scarcely should. I should prefer a tonic of a more simple nature, such as gentian or quassia. If, however, I had not a more simple tonic by me I should prescribe it.

Would the other ingredients besides those you prefer alter its character as a tonic ?—They make it a stronger one.

Supposing you prescribed gentian, would the preparation of spirit be greater or less ?—I have not analysed the mixture.

Supposing this to be proof spirit ?—It is not proof. Proof spirit is 100, and this is only 67.

Assuming it to be 67, would it be less than you would prescribe ?—It would be less.

In prescribing tincture of gentian you would be administering more spirit than there is contained in this tonic ? —Yes.

Mr. Travis : You do not mean to say if you prescribed tincture of gentian you would tell the patient to take a glass whenever he liked ?

Dr. Rollit remarked that tincture of gentian was more concentrated.

Dr. Rollit : We will take it that you prescribe tincture of gentian, would you tell us what amount you would give ?—If a patient came to me in the morning, say 10 or 11 o'clock, and said he felt exceedingly depressed, that he had perhaps been taking wine too freely the night before, I should not have the least hesitation in giving him six drachms of gentian, or an ounce of tincture of cardamoms, which would contain the same quantity of spirit. There would be about one-third less of spirit if he gave this medicine than in six drachms of gentian or an ounce of the tincture of cardamoms.

So that the distinction between the tonic and the medicine you would prescribe would be the presence of a greater number of ingredients and less spirit in the former ?—Yes.

Are gentian and the other ingredients recognized drugs in the medical profession ?—Certainly, as tonics and carminatives.

Would you describe this as a beverage ?—No, as a medicine, and a very nasty medicine, too. (Laughter.) I should be very glad to get the taste out of my mouth.

If you treated it with water, would it become more refreshing ?—That would make it more bitter.

And you say that no person with an ordinary sense of taste would take this for a beverage ?—Certainly not.

You don't think any person would become addicted to it ?—I think not, when there are so many other things so much more pleasant.

If a person wished to imbibe spirit covertly by going to a druggist instead of a public house, is there anything more pleasant in the Pharmacopœia ?—Nothing more delightful than compound tincture of cardamoms taken in aromatic spirit of ammonia.

With regard to the question of dose, what is understood by a small wine-glassful ?—It is a little over an ounce, about nine drachms. To be taken once a day the dose would not be excessive. If taken three times a day, I think the bitters, the ingredients, would have such a dry effect on the passages that the tonic would be deleterious; not that the quantity of spirit would be deleterious, but the ingredients in solution. An ounce of tincture of rhubarb was frequently taken by ladies, so that an ounce was a recognized dose in the Pharmacopœia. An ounce of tincture of rhubarb would contain 30 per cent. of spirit more than this tonic.

And that would be given in as large a dose ?—Yes, to be taken occasionally.

By Mr. Summers : What do you call this preparation, Doctor, a tincture or a compound ?—I can scarcely answer that question, tinctures are compounds.

Do not tinctures contain a larger quantity of spirit than compounds ? You have already mentioned tinctures of rhubarb.—Yes, that is a compound tincture.

And contains, you say, more spirit ?—Yes ; 30 per cent.

So that it would be nearly 100 ?—Yes.

You say you describe this as a pure and simple medicine ?—Certainly; as a stimulant and tonic.

Will you taste this bitter (handing to witness a bottle) ? —Witness: It is very much stronger of spirit.

Mr. Summers : This is the ordinary commercial bitters, and contains 60 per cent. of proof spirit.

Dr. Rollit: You have been asked about the compound tincture, will you tell me the purpose of the spirit ?—It is merely to take up the medicinal ingredients. If the preparation was not required to be kept, less quantity of spirit would serve.

Would it be possible, bearing in mind the presence of the gentian and other matters, to abuse the use of this medicine ?—Any stimulant or liquid may be abused if a man is bent on getting alcohol. I knew a janitor who drank spirits out of the jars in which we had diseased preparations. (Laughter).

To any ordinary man, would the presence of these ingredients prevent him taking it regularly?—I should say so.

Is there not a distinction between public-house bitters and this compound?—I have had so little experience of public-house bitters.

But I limit your experience to the one produced of which you have tasted.—It is more pleasant than the tonic.

You would not think the selling of the tonic a mere colourable evasion for the purpose of taking spirituous liquors?—No.

Mr. Travis drew attention to the label: "A small glassful at any time. When mixed with a little sherry it forms a milder and agreeable tonic."

Witness: It does not say it is to be continued.

Dr. Rollit: We call it a "morning tonic" on the label produced.

Dr. Walton was then examined: I have been a practitioner in Hull for about twenty years, and I have also had experience as a chemist and druggist. I have examined and tested the tonic produced. It contains 35·2 of alcohol. The presence of spirit in the compound is less than in many tinctures in the Pharmacopœia. There is about 13½ less of alcohol than in Nicholson's gin. There was rather more than half a scruple of solid extract in each ounce. Sugar and bitters were present to a considerable extent in the tonic. Under certain circumstances, I would, as a medical man, administer the tonic, taking it to contain what is described.

Is it properly described as a beverage or a medicine?—I have never heard of any one putting a teaspoonful in the mouth, as one would rum or brandy.

You would describe this, then, as a tonic or a medicine?—It is a medicine.

Is it such a compound as might be abused in its use?—Not twice by the same person. He would be satisfied by one or two trials, it is so excessively nasty. It is very nasty. I once took a dose at ten o'clock in the morning, and could not get rid of it till night.

If a man wanted to take his spirit in the shape of physic, are there any pleasanter means than this?—Yes, tincture of cardamoms and gentian, that is a common thing to give.

Is the dose placed upon the label excessive?—No.

Would it be injurious, either from the quantity of spirit or the ingredients, supposing it to be taken every morning?—There would really only be about 30 per cent. of alcohol in a wineglassful, which is the dose. Most of the vegetable tinctures will be given from one drachm to an ounce. The dose will depend on the concentration of the tincture. This, so far as the spirit is concerned, is a diluted tincture. The solid matters were present in such a quantity as to be distinctly curative.

The witness was handed two samples of public-house bitters to taste, and he said: The tonic is not a mere public-house bitter. Sherry is often a medium for taking a thing of this sort.

Mr. Summers: Will you say what there is in the tonic produced that differs from the public-house bitters?—There are a great many things in the bottle produced which are not in this.

Are they not simply flavouring matters?—No, chiretta, which is in one and not in the other, is a most powerful bitter. The tonic is a medicine and not a beverage. No one would take it a second time unless it were ordered as a medicine.

Re-examined: There is no similarity between the tonic and the bitters. The presence of quassia in the compound creates a great difference between the two.

Mr. Travis: Though you say it would not be a beverage, supposing you take it for the purpose of mixing it with large quantities of wine, is it not a beverage then?—It would spoil the wine. It is a tonic and stomachic, and the object of mentioning the sherry is to make it as pleasant as possible. I would do it myself, but it does not make it a beverage.

Mr. Travis: You would only take the proper quantity of it?—I would not take it at all if I could help it.

Mr. Jas. Baynes, jun., pharmaceutical and analytical chemist, said: I have made a careful analysis of the morning tonic. It contains 67·382 of proof spirit; the solid residuum is 3·1 per cent., and the ash only ·2. I should think the quantity of spirit was not more than sufficient for extractive purposes. I produced the residuum of the tonic, as also that of the analysis of a publican's bitter. They are very different in colour, and one contained 3·1 per cent., while the other had 10·08 per cent. of residuum. There was scarcely any trace of sugar in the morning tonic, whilst the greater part of the residuum of the publican's bitters was sugar. The solid constituents of the compound were about the same as Pharmacopœia tinctures; and the spirit was nearly 33 per cent. less. I should think the tonic could not be taken for a beverage. It is often left to the patient as to when he should take the medicine.

In reply to Mr. Travis, witness said: Were it not a breach of etiquette I could show you, in a prescription book, prescriptions for certain medicines to be taken "if required," and "occasionally" is also a frequent word.

Mr. Anthony Smith, President of the Hull Chemists' Association: I have been in practice as a dispensing chemist for twenty-one years. During the whole of the time I have been in business it has been usual to dispense such compounds as the one produced. The mixture is decidedly such an one as I and others would dispense as a medicine. If I were asked or wished to gratify the palate of a person who simply desired some spirits I should most decidedly not administer the mixture produced. I should give a compound tincture of cardamoms from the Pharmacopœia, or a simple tincture of orange alone. Bottles like the one produced are frequently used, because they can be obtained second-hand from some family customer. They would cost about one shilling per dozen, and medicine bottles about half-a-crown a dozen. There was nothing unusual in the reading of the label so far as the chemist was concerned. Every day we receive prescriptions where the direction is "to be taken occasionally," "to be taken when necessary," or "to be taken when required." The word "occasionally" is used by all the leading physicians in the kingdom in their prescriptions. The tinctures of the Pharmacopœia generally contained more spirit than is in this compound.

Mr. G. Myers, Vice-President of the Hull Chemists' Association: I have heard the evidence of Mr. Smith, and concur entirely with it. The label with the words "to be taken occasionally" is similar to what is frequently employed. I believe it is the invariable practice of the trade to give the same label with quinine wine, "to be taken occasionally."

Mr. Summers: Do you know what number of grains per ounce is contained in quinine wine?—I cannot say from memory.

Do you know that unless there is one grain per ounce of solid matter in it, an Excise license must be taken?—I do not.

Mr. F. Earle: I have been in business as a chemist in Hull for fourteen years, and I entirely concur with the evidence of Messrs. Smith and Myers, as to the label.

Mr. C. B. Bell, Secretary to the Chemists' Association: I have been in the trade twenty-one years; I agree with the evidence of Messrs. Smith, Myers, and Earle, as to the label. I have tasted the tonic; it is a medicine, and a very nasty one.

Dr. Rollit then addressed the court, and begun by pointing out the importance of the case to the trade of the chemist. He was instructed on behalf of his client and those associated with him not to take any technical objection, but to ask for a decision on the general facts of, and principles involved in, the case. He referred his Worship for a moment to the state of the law on the question. In order to sell spirits off the premises an Excise license must be obtained, where those spirits were sold in less quantities than a reputed quart, and no quantity of spirit could be sold merely off the premises in a less quantity than a quart. Therefore, if tinctures were held to be spirits, they must be prepared in quantities not less than a quart, and in that case a license must be obtained from the Inland Revenue in order to sell them. It amounted to this, therefore, that a small quantity of tincture could not be sold off the premises,—for instance, a small bottle of essence of ginger,—and no quantity under a quart, could be sold. Again, if the tinctures were held to be spirits, a single teaspoonful could not be consumed on the premises without the license of the Excise and a certificate from the magistrates. In other words, if these compounds and tinctures were held to be spirits, and they were sold off the premises, at least a quart must be purchased and a license procured from the Excise; and if consumed on the premises in the smallest quantity a license must be obtained from the Excise, and also a certificate from the magistrates. The druggist's shop would therefore really be turned into a public house, and any person might demand to be supplied with any spirit he chose. His Worship, he should think, would shrink from a decision which involved such consequences as these. Dr. Rollit went on to point out that if these things were held to be spirits, after the closing hour prescribed by the Act not one of the simplest of tinctures, such as tincture of ginger, a very common article, could be obtained, not even in the large quantity of a quart. Up to the present the Inland Revenue had not interfered in a matter like the present, simply because these things were held to be medicines, and were dispensed to the public as such. It appeared to him (Dr. Rollit) that the chemist was under governance of a higher law than man's, the law of humanity, which directed that he should help to heal the sick, even if it were by dispensing medicine in breach of Licensing Acts! The question his Worship had to consider was this: had the defendant been selling a dram, a mere beverage, under colour that it was a medicine, or was it *boná fide* the latter? His friend opened his case on the same ground, appealing to the taste as confirming his view. With the exception of the chemist whom Mr. Summers called, and who said this tincture was similar to the publicans' bitters, the whole of the witnesses, Dr. King and the rest, had stated that the mixture was very objectionable to the taste, and that had a man wanted to gratify his palate out of the Pharmacopœia, there were other things infinitely more agreeable. Supposing this tonic were even agreeable to the taste, surely the very triumph of medicine and surgery in our day had been the amelioration of pain, and nasty taste was a form of pain. But it was, he submitted, proved that the medicine was disagreeable to the taste; and, so far from its being acceptable, the medical evidence had shown a strong reason why a man would not continue it—viz., that his whole system would be dried up by the tonic qualities of the compound as to prevent one from taking it glass after glass. Then, again, in respect to the question of price, which was one means of finding out whether this compound would be likely to be used as a beverage or not, it was not only excessively nasty, but very far from being cheap. It was dearer, unquestionably, than brandy, and therefore one would imagine that if a person had the drinking of spirit in view he would use brandy in preference to this mixture. But it appeared to him that this argument was almost beside the question, for were the tonic cheap, it would be one of the reasons which would make it as a medicine more advantageous to the public. Now, with regard to the question of the bottle, he ventured to submit that this was a point that had been quite explained away so far as his friend's case was concerned; its having been proved that the bottles were used for economy's sake. Let him next consider the mode of sale. There was no evidence that the tonic was prominently exhibited in the window, that it was even made up and ready bottled for immediate use. On the contrary, he (Dr. Rollit) believed that the person purchasing it had to call two or three times before he could obtain it. Surely, had this been a mere beverage which people were asking for day by day, had Mr. Staning been selling it as a medicine, as a mere subterfuge for breaking the law, surely his object would have been to have had bottles ready and even exposed for sale. He submitted that the mode in which it was dispensed was the same as in the case of all other medicines supplied by Mr. Staning, and that this was a strong argument in his favour. Now, with regard to the question of its being a dram. If it were a mere public-house bitter, no one would question the legality of the course the Inland Revenue had taken; but it had been proved in the witness box, with regard to the taste, colour, and by the residuum, that there was not an atom of similarity between the bitters on the one hand and this tonic on the other. The conclusion to be come to on this head was that the publicans' bitters were found to contain a great quantity of saccharine, while in this tonic the chief ingredients were bitters which are unacceptable to the taste. Next, with respect to the question of the dose, he must draw his Worship's particular attention to the reading of the label. He contended that it was not too large, and would be the same practically as prescribed by a physician, the tonic not being so concentrated as some of the tinctures that had been named. Then as to the label, the words "morning tonic" were the prominent words upon it, and moreover, gave it its name. Surely a "morning tonic" could not be twisted into something to be taken in the evening. They must construe the other directions on the label with the words he had quoted, and judge of the implication that was suggested; whether it did not mean that it was a tonic to be occasionally taken in the morning as the patient thought desirable. A "morning tonic" could not be thought to mean something to be taken three or four times a day. Then as to the words, "when taken in a little sherry it forms a very agreeable tonic," that implied that it was not agreeable to the taste taken alone. Dr. Rollit referred further to the evidence of Mr. Hunt—than whom there was not a more abstemious man in Hull—and said he had taken it for its curative properties and with advantage. In conclusion, he submitted that there was not the slightest ground for saying there had been any evasion of the law, that the dose was not such as would be deleterious, that his witnesses had been unanimous in describing it as a medicine and not as a beverage, that it had been proved there was less spirit in it than in ordinary tinctures, and that it was entirely different from the bitters sold by the publican. He asked his Worship to put a reasonable and liberal construction upon the Act of Parliament, and to say that the sale of a medicine, or what should be properly described as a medicine, was no breach of the Act.

Mr. Summers said, in reply, that the contents of the bottle had been analysed, and it was found that the "morning tonic," so called, was nearly similar in character to the bitters sold by publicans and others, so that a license would be required to sell it.

Mr. Travis: There is no spirit licence taken out for bitters.

Mr. Micks (collector of Inland Revenue): No person could get a special licence for bitters; only a person to sell them must have a licence for the sale of liquors.

Dr. Rollit: That makes it a public house.

Mr. Travis: Supposing a man wanted to sell bitters exclusively, would not that require a licence?

Mr. Micks: Oh, certainly.

Dr. Rollit: I think that is admitted.

Mr. Summers said that under the 16th George II., Chap. 8, Sect. 12, it was provided that the law as to licences should not extend to any physicians, apothecaries, surgeons, or druggists, with respect to medicines made up for lame, sick, or distempered persons. The question there was whether this was a medicine or not.

So far as this bottle was concerned, various witnesses called said it was a medicine and not a beverage, but the label certainly would lead any person to a different conclusion, for, as it says, this tonic taken in a glass of sherry is a very agreeable tonic. The Inland Revenue should have no desire to strain this matter as against the defendant, or the trade to which he belonged, so long as their business was carried on properly, but his Worship would see at once that in the event of a chemist or druggist being permitted to make up tonics of this kind in simply a little colouring matter, so as to take away from them the character of pure spirits, the chemist and druggist might carry on business when public houses were closed and at other times, and a person would go into a druggist's shop who would not go into a public-house.

Mr. Travis said he did not think it mattered what was the quantity of spirits contained in the liquor. If it was not made up as a *bonâ fide* medicine, the defendant would be liable. He (Mr. Travis) could not lay down a principle which would regulate all cases of this nature, as each case—if any more were put before him—would depend upon a separate class of facts. The label on the bottle was a most condemnatory label, and he agreed with Dr. King that it was not wise to leave to the discretion of the patient the taking of a wine-glassful of a preparation at any time he thought proper. Whatever was the result defendant must thank himself for what had occurred. This was the first case of the kind, and it was hardly one in which he thought the Excise would press severely.

Mr. Micks said that whatever was the decision of the Magistrate it would be satisfactory.

Mr. Travis, in intimating that he would give his decision in a few days, remarked that if he agreed to respite judgment, it must be understood that loose labels of this sort should not be used, perhaps opening the door to evasions of the law.

The Alleged Poisoning by Corrosive Sublimate.

Mr. Holl, acting for Mr. Carter, coroner for East Surrey, resumed at Saint Thomas's Hospital, on Monday, the inquest on Celine Marin, a French woman, who was alleged to have died from the effects of corrosive sublimate administered by mistake under circumstances already narrated in this Journal. The inquest has been three times adjourned, chiefly owing to rumours prevalent in the neighbourhood, which the police, directed by Inspector Cook, of the E division, were instructed to sift. The only additional evidence given on Monday was that of Eugene Bonis and Jean Putzera, both of whom spoke briefly of having seen or heard of a woman serving in the shop on former occasions.

In reply to an inquiry by a juror a medical certificate was handed in stating that Mr. Kupitz, the assistant, was unwell and unable to attend. In support of his statement when under examination that he was "a member of the Pharmaceutical Society," Mr. Kupitz sent the Registrar's acknowledgment of the receipt of his claim to be put on the Register of Chemists and Druggists, sent in before the 31st December, 1868.

The Coroner remarked that Mr. Kupitz's name did not appear on the Register of Chemists and Druggists for 1874; but he did not think that fact pertinent to the present inquiry. As to Mrs. Kant, he did not think that she had committed an offence against the Pharmacy Act, since she did not keep an open shop for the sale of any of the poisons included in the schedule to that Act; neither had it been shown that she was in the habit of selling those poisons. She had apparently sold soaps, scents, glycerine, and such simple articles, in the absence of the qualified assistant, and it was whilst endeavouring to serve a customer with a substance that was not in itself poisonous that the mistake was committed which led to the fatality. He would now put it to the jury whether the case was not one of misadventure which might have happened to anybody. The time that had been spent in its investigation, however, was not lost, as the attention called to the matter might be the means of preventing the deplorable practice of drugs being served by persons not properly qualified.

The jury returned a verdict of "Death from misadventure."

Reviews.

Materia Medica and Therapeutics. Vegetable Kingdom. By Charles D. F. Phillips, M.D., F.R.C.S.E, —London: J. and A. Churchill. 1874. (8vo., pp. 584.)

There already exist so many treatises and text-books with titles more or less similar to that which stands above, that one is naturally inclined to somewhat critically examine the claims to notice of any addition to their number. The title tells us but little; we are equally prepared to find in the book anything or everything comprehended in the departments of the technical botany of medicinal plants, the history, chemistry and physical properties of drugs, and the action of medicines. However, what we discover the book actually to be is a treatise on therapeutics. The author tells us in his preface that he has aimed at "bringing together in a moderate compass a more extensive series of facts respecting the action of drugs, and especially a more enlarged view of what has been done in other countries, than will be found in the ordinary text-books," and it is certainly a sufficient justification for the *prima facie* crime of adding a new "materia medica" book to our shelves, that it gives us, instead of the usual *réchauffé* of old-fashioned botany and chemistry, extended information about medicines from the point of view of a modern physician, familiar himself with their use and conversant with the observations and researches of others.

It seems at last to be becoming recognised that the attempts so long and persistently made in lectures and text-books to say everything that can be said about medicines in all their various aspects, are futile. It cannot be too strongly insisted upon that the botany of drug-yielding plants, the composition, nature, and preparation of the drugs themselves, and their action on morbid states of the human organism, are all subjects of separate inquiry. Their forced union has been most unfortunate for the student of medicine, who has had his attention directed away from the, to him, all-important study of the therapeutical action of medicines, by a heterogeneous mass of facts and fiction quoted at second hand, presented to him in an unattractive and disconnected form, and obviously serving no useful purpose in his education as a practitioner.

How interesting the study of Pharmacology may become it is unnecessary to say; the pages of Messrs. Flückiger and Hanbury's 'Pharmacographia' have just given us fresh evidence of it, if any were needed. The botanist and the chemist, too, do not require to be told of the various problems and questions of interest as to the origin and chemistry of drugs which still remain to be solved at their hands. What is contended is, that these are special lines of research, and have no necessary or close connection with therapeutics.

The author of the present book has, we think, fairly succeeded in carrying out the object expressed in the above extract from the preface, but he has not been able to entirely give up botanical and chemical descriptions. He has endeavoured to retain their "useful parts" and omit the "superfluous," and the result does not appear to us very satisfactory. We find the plants placed, indeed, under the Natural Orders, but these Orders follow no recognised sequence; this the author considers a point "of little importance," but it was surely going out of his way to set at nought every principle of arrangement by placing, for instance, *Smilaceæ* between *Myrtaceæ* and *Simarubeæ*, and *Melanthaceæ* flanked by *Corylaceæ* and

Salicaceæ. Surely even alphabetical order would have been preferable to such meaningless juxtapositions. We are, on the whole, also inclined to think that the book would have lost little by the omission of the section headed *Description*, which commences each article. This gives a very short and meagre account of the aspect, characters, and native country of the plant; though usually correct, the information here is too slight to be of value; in not a few cases, too, we find statements considerably behind the time, and there are a few decided blunders. Under the second head, *Active ingredients*, we have a brief notice of the constituents of importance in a medicinal point of view, inert substances being omitted.

It is the sections devoted to *Physiological and Therapeutic Actions* which constitute the bulk of the volume, and in which the value of the treatise lies. In the more important drugs these remarks extend to the length of many pages. The first portion states the results of experiments and observations on the effects which the drug is capable of inducing in the healthy body, and the second deals with its therapeutic action in disease. This Journal is not the place to speak in detail on medical matters; it is sufficient to say that the whole subject seems to be well brought up to date, recent researches, both at home and abroad, being quoted and discussed. Many original observations on the employment of medicines will be found scattered through the book, and as not a few of these relate to drugs which are not in common use in this country these practical remarks have a special value. It is to be wished that definite references to the sources of information had been more systematically given. The therapeutical uses are arranged under the heads of the various diseases in which the medicine has been employed. A fifth section enumerates the various preparations and doses.

Two very full and complete indexes complete the volume, which will be read with profit and interest by both students and practitioners of medicine.

Obituary.

Notice has been received of the death of the following:—

On the 7th January, 1875, Mr. T. E. Edwards, Chemist and Druggist, of Widcombe, Bath. Mr. Edwards had for twenty-one years occupied the post of dispenser at the Bath Royal Hospital.

On the 7th January, 1875, Mr. Henry Tomlinson Todd, Chemist and Druggist, of Newcastle-on-Tyne.

On the 10th January, 1875, Mr. Owen Lloyd Jones, Chemist and Druggist, of Bettws-y-Coed. Mr. Jones had been a member of the Pharmaceutical Society since 1871.

On the 13th January, 1875, Mr. Richard Oakley, Chemist and Druggist, of Gornall Wood, Staffordshire.

On the 19th January, 1875, Mr. Edward Cotterell Darby, Chemist and Druggist, of Broad Street, Worcester.

In the announcement, on p. 579, of the death of Mr. Forbes, he is erroneously described as "of Reading;" it should be "of Reigate."

THE HOURS OF BUSINESS IN PHARMACY.

Sir,—I was not at all surprised to hear of the illness of "Veritas," as it was a natural consequence of the close confinement he underwent as an apprentice and assistant in an atmosphere contaminated with the noxious emanations from poisonous drugs, which has undermined many a strong constitution. This is testified by the pale and emaciated faces of the majority of pharmaceutical chemists, and if no other argument could be brought forward in support of the early closing movement, that would be sufficient to show that it justly claims the consideration of every pharmacist.

I am not the only one who, in the opinion of "Veritas," does not evince "intelligence" in seeing no difference between a chemist's business and that of grocers, etc., in the matter of early closing, as he will see by reading the latter part of an editorial article on page 491.

The experience of "Veritas" in modern pharmacy must be very limited indeed if he thinks a sleeping draught cannot be procured when the shop is closed. At most of the pharmacies in the town I write from, as at Bedford, the principal, or one of his *employés*, is always on the spot after the shop is closed to supply medicine required in urgent cases. Sometimes medicine is required in the night, and according to the method of reasoning adopted by "Veritas," the shutters should be down and the gas flaring, otherwise the patient cannot have the prescription dispensed. Certainly your correspondent "does not evince intelligence," to use his own expression, in bringing the "sleeping-draught fact" forward as an argument against early closing; on the contrary, it is one of the strongest arguments in its favour, for when a grocer, draper, or ironmonger is closed, his day's labour is ended.

He also cannot, or will not, see, that in many businesses an assistant could frequently have an hour or so for study without injuring his employers. If he reads the advertisements in the *Pharmaceutical Journal* he will frequently see such phrases as the following:—"Duties light; time for study," "Would suit a man studying for the Minor." Under such circumstances many have acquired sufficient knowledge to pass the Minor examination in a creditable manner, and I venture to assert that if some such arrangement as that mentioned in my "second stipulation" could be more generally adopted it would do more towards crushing the giant "Cram" than any scheme which has hitherto been proposed, and the Society would doubtless have less cause to complain of so few candidates for the non-compulsory examination.

"Veritas" wishes to know why many employers prefer not to have a "Square" man. I answer: first, they would in many instances have an assistant whose scientific knowledge exceeded their own. Second, the services of one who has not passed the examination may be obtained for a smaller salary.

As the remainder of his letter has no bearing whatever on earlier closing, or opportunities for study (the subjects of my former letters), it is unnecessary for me to make any further comments upon it.

AN EXAMINED ASSISTANT.

Sir,—In replying to the query of "Veritas" in last week's Journal, I have much pleasure in informing him that I spoke "to the card" with regard to the number of assistants kept in Bedford. Most of the chemists have three or four young men to assist them, *i.e.*, assistants and apprentices. Perhaps "Veritas" will say you cannot call an apprentice an assistant. I beg to inform "Veritas," however, that each apprentice is equal to a junior assistant after being there a short time, and to prove my words I can assure him that one of the apprentices passed his "Minor" in honours before he was out of his time, and another soon after, without going anywhere to study, thanks to the early closing movement. How could they have done so if they had had to work in the shop late at night? My opinion is that it is not necessary to keep pharmacists' shops open later than seven o'clock, and that one assistant is sufficient to stop in, when ordinary business is over, to dispense sleeping draughts or any medicine required. It is not necessary to keep all in for the sale of sponges, sponge gloves, tooth-brushes, powder, etc., and a number of things that the public could wait for until the following day, quite as well as the gent who wants a book or the cook the lard. By serving only medicine you would relieve two out of three assistants every night, and hence give them the evenings for study, which would enable them to pass their examinations.

A. W. Waring.

January 19th, 1875.

Sir,—I think the first query of "Veritas" as to why many masters prefer not to have a "Square" man can easily be answered. Of course the apprentices of the good old times (say twenty or twenty-five years ago) are apprentices no longer, but many of the masters of the old school are existing, hale and hearty as ever, and retaining their prejudices for old customs. They did not pass examinations, but served stringent apprenticeships, and having acquired a thorough practical knowledge of their trade, think that that is all they require in their assistants.

With regard to the preparation of night draughts, which "Veritas" speaks of in his third paragraph, they could be prepared and left at the patient's house in the day, and in a serious case the physician would probably let the druggist know what medicines the advanced stages of the ailment would require. A doctor is not in the habit of knocking up a chemist nightly with a fresh prescription to be got ready in an hour.

Anyone who is cognisant with the pharmaceutical world can affirm, without fear of perjury, that the average number of chemists who begin with £200 or £300 and retire with £500 a year at forty, would be nothing like a twentieth part of the community.

A. Warren.

Sir,—"Veritas" seems, in keeping his shop open to a very late hour, to be actuated by a very laudable desire to alleviate the "sufferings of distressed humanity." "Two sleeping draughts," he says, "will not be taken the next night, to make up for the one missed on this."

Certainly not, but as sleeping draughts may be required as likely at four o'clock in the morning as at nine o'clock in the evening, parties by calling at their chemists' house can have their medicines prepared, without the chemist or his assistant waiting a whole evening, in expectation of a draught being required. When people know that druggists' shops are kept open very late they are, of course, in no hurry to procure their medicines, for it is a well-known fact that patients who feel unwell all day, in many cases wait till the last moment, expecting to get better, and, then, when they find that all places where medicine can be procured are about to be closed, they suddenly discover that they require the attendance of a medical man, and consequently require medicine. But if "the last moment" at which medicine can be procured be fixed at an hour earlier, the result will be that parties will call an hour earlier.

I believe in an improved future for druggists in the shape of early closing, without taking the very sarcastic advice which "Veritas" gives us. Nearly eighteen months ago in our town we got the hour for closing changed from 9 p.m. to 8 p.m., and no inconvenience has arisen from the change. A petition was drawn up and signed by the assistants and apprentices, and presented to the medical men, requesting their assistance, which (all honour to them) we received. Armed with the promised assistance of the doctors, we then waited upon our masters, who, like the medical men, granted our request. It was then advertised in the local paper for three weeks, and no one has suffered from it. The same plan has been successfully carried out in some of the neighbouring towns.

"Veritas" certainly gives young men very little encouragement to study. It seems rather strange that a young man who employs his leisure hours in study, and who succeeds in passing his examinations, is informed upon applying for a situation "that the preference would be given to one who has not passed the examinations."

A Country Student.

Sir,—As a careful reader of the Journal I have perused the letters upon the subject introduced by "An Examined Assistant," and think one important point to consider in this matter is the danger which would result from the estrangement of thought advocated by "An Examined Assistant." The accidental substitution of poisonous medicaments is unfortunately not unknown in the trade, and is probably due to "absence of mind."

I quite agree with "Veritas" that in any well-appointed pharmacy there is sufficient work to employ the assistant, if he is not a mere articulating machine requiring to be reminded continually of the work to do, or content to attend behind the counter and supply only that which is asked for.

The remark of "Veritas" that a pharmacist may commence with £200 or £300, and retire in twenty years with a fortune of £10,000, will probably astonish "An Examined Assistant," and does certainly refer to some very exceptional case, nevertheless if "your heart" is in the business it can be carried on with advantage, and with half the manual labour of the trades referred to.

Observer.

Sir,—I trust young men who, like myself, have entered the business of a chemist and druggist, will not be led to overrate the pecuniary advantages of the business by the remarks of "Veritas" in the last issue of the Journal. He says a young man with £200 or £300 to commence with, may confidently hope to retire on £500 a year by the time he is forty, or on £1,000 a year by the time he is fifty.

There is no doubt it will be an easy matter for him to "confidently hope," but he must not trust to the above, or in ninety cases out of one hundred he will be disappointed. This will be seen by the daily advertisements of businesses for disposal, which are generally to the effect that the incoming must be equal to the returns or nearly so; therefore according to "Veritas" a young man who invests £300 in a business, and receives returns, as we presume, adequate to the ingoing, must lay in store the whole of the returns to produce results as stated by "Veritas," which he could not accomplish if the returns were £600, double the ingoing, after deducting cost of rent, taxes, housekeeping, and other incidental expenses. Of course a realization of £500 a year may be effected in the drug trade by the time a man attains forty years of age, but not with an expenditure of £200 nor yet £300.

"A Young Observer."

January 19th, 1875.

A Problem.

*Suggested by the letter of "*Veritas*" in the* 'Pharmaceutical Journal' *of January 16th.*

A pharmaceutical chemist commences business at the age of twenty-five years with a capital of £300. He retires with £10,000 (or as much as may suffice to being him in £500 a year) at the age of forty: what must his average yearly returns be, supposing his profits to be 50 per cent. of his returns, and his personal and household expenses 50 per cent. of his profits?

H. J. C.

Cambridge, January 16th, 1875.

Sir,—"Veritas" must indeed believe in an improved future condition of the drug business when he speaks of a chemist commencing with £200 or £300, and retiring at the age of forty upon £500 a year, and at fifty upon £1,000 a year.

If there is any chemist living who has done this clever trick I should like to make his acquaintance.

R. Huggins.

MIST. GENTIANÆ COMP.

BY CHARLES SYMES, PH.D.

This preparation, after having undergone some amount of transition, both in character and name, has become a comparatively popular medicine, being daily prescribed by many practitioners; it still, however, admits of some improvement.

In the P. L., 1851, it consisted of

Inf. Gentianæ Co.
Inf. Sennæ Co.
Tinct. Card. Co.

Banished in name from the B. P. of 1864, it existed there in composition as Infusum, not the old mixture, not the infusion of the P. L., but that of the U. S. Pharmacopœia, which in the present B. P. receives the name of Mist. Gentianæ Co.

Now there can be no objection to copying from the Pharmacopœias of other countries, either continental or transatlantic, but we certainly should show our discretion by avoiding their faults. When we copy Pulv. Glycyrrhizæ Co. from Prussia, we improve it into something which the bulk of the profession object to prescribe; but when we copy the U. S. Inf. Gent. Co. we take it, faults and all, even though dissatisfaction had been expressed concerning it in the country of its origin, and although some slight modification is introduced, it tends rather to increase than diminish its unsatisfactory appearance.

When this preparation has been kept a few days it commences to throw down a flocculent pectic-like deposit, which floats near the bottom of the containing vessel; the upper half of the fluid might be poured off moderately clear, but the lower portion will be exceedingly turbid, unless it is filtered through paper, after which slow process it is too bright to correspond with the former, and thus two mixtures made with these portions respectively will have a somewhat different appearance. This, perhaps, is only a small difficulty, but one which causes frequent annoyance to the dispenser, and is quite worth surmounting. To do this satisfactorily it is necessary to consider, first, the characters of the materials we have to deal with—gentian, orange-peel, coriander seeds, and as menstrua or solvents, proof spirit and water. From the gentian we desire to extract the bitter principle soluble in both the latter; from the orange-peel a small quantity of aromatic bitter principle and some volatile oil, and from the coriander, volatile oil, both sparingly soluble in water, more so in proof spirit. To accomplish this we are instructed, first, to macerate the ingredients with the proof spirit for two hours, and then to add the water and continue the maceration for a like period, resulting in the preparation above described. If the proof spirit and water be divided respectively into three portions and the three ingredients are treated with these separately, according to the Pharmacopœia directions, and the strained liquors are placed in separate bottles, the coriander solution is clear, the gentian and the orange *slightly* turbid. In a few days a flocculent deposit begins to form in the latter, so that on slight agitation it will be seen that the turbidity has much increased; the gentian changes very little, the coriander not at all. From our experience in the manufacture of Tinct. Aurantii, we know that proof spirit dissolves nothing from the peel which produces this deposit, and we conclude that the water subsequently added does this. Experience thus gained points us to another experiment as follows:—In one vessel place the coriander seeds and orange peel, pouring on them the proof spirit; in another place the gentian, pour on it the water; at the end of two hours strain off separately and mix. Mist. Gentianæ Co. is thus produced in one half the usual time, possessing the full aroma of the flavouring ingredients, the bitterness of the gentian, and a brightness similar to that of its infusion. Samples which have been kept two months have undergone no change, other than the very slight deposit which always occurs in fresh infusions after standing a few hours, and from which the clear liquid is readily decanted.

It might require some caution on the part of one decidedly opposed to *concentration* of infusions to recommend it here; but giving my readers credit for readily distinguishing between things which so widely differ, I do not hesitate to point out that in the case of Mist. Gent. Co., not only is it unobjectionable, but positively beneficial. In treating the gentian by the B. P. process, or by the modification indicated above, a quantity of mucilaginous matter is dissolved by the water, which to say the least is undesirable; by concentration in the following manner this is readily got rid of. To produce one pint—

Take of bruised coriander seeds } of each 240 grains.
Bitter orange peel . }
Pour on proof spirit . . . . 16 ounces,

and set aside to macerate.

Gentian root very thinly sliced (or better in coarse powder) . . . . 2 ounces.

Pour on this, distilled water, rather more than sufficient to cover it, allow to stand one hour, pour off the liquor, and repeat the process to the third or fourth time, when less than a pint of fluid will be obtained, and the exhaustion will be completed; evaporate to four fluid ounces, and mix with the tincture previously strained from the coriander and orange peel. The mucilage is precipitated by the spirit, and by filtration a bright concentrated liquid is produced, which keeps as well as any tincture, and on dilution in the proportion of one part to three of distilled water forms Mist. Gentianæ Co. that will compare favourably with, and contain nothing which is not contained in that freshly prepared by the Pharmacopœia process, and over which it possesses the decided advantage of keeping a longer time without change.

Liverpool, January 20th, 1875.

THE PRESENCE OF LEAD IN OIL OF LEMON.

BY HARRY NAPIER DRAPER, F.C.S.

In common with many others for whom the subject must have had interest, I read Dr. S. Macadam's paper (*Pharm. Journ.*, Jan. 16th) "On the Presence of Lead in Aërated Waters." Some of the author's experiments, and the deductions made from them, struck me as worthy of more attention than was given to them in the discussion which followed the lecture.

One or two of these I shall mention presently, but I wish more especially to comment upon the statement that "oil of lemons is often loaded with lead."

I think I shall be able to show that while we have to thank Dr. Macadam for indicating that lemon-oil may contain lead, we have not any reason whatever for anxiety on this score, or for fear that from this cause lemonade may be harmfully contaminated with lead.

I fortunately happened to have the means of making the following experiment:—

An ordinary copper of superfine lemon-essence, shipped at Messina in February 1874, had remained unopened until the 20th inst.; that is, its contents had been in contact with its metallic lining for at least eleven months. This copper was opened, and a pint (= ·567 litre) of the essence removed and treated as follows:—The essence was mixed with 25 grammes of acetic acid, strong enough to dissolve in it without turbidity, and after standing for an hour, 100 grammes of distilled water were added, so as to withdraw the acid. The supernatant essence was separated by decantation and a wet filter from the acid liquid, which was next evaporated to about 10 c.c., again acidulated with acetic acid, pure sulphuric acid added, and double the volume of the whole liquid of alcohol. The mixture was now allowed to rest for twenty-four hours, and the precipitate which had formed collected on a filter, which when dry was with its contents ignited and weighed with the usual precautions. The lead sulphate thus obtained weighed 0·0248 grammes, which represents 0·0182 grammes of metallic lead. Reduced to English weights and measures, we have thus the result that a pint of essence of lemon contained 0·281 grain, that is a little more than a fourth of a grain of lead. Mr. Umney (*Pharm. Journ.*, p. 584) assumes that the quantity of essence used in making lemonade syrup seldom exceeds 0·15 per cent., and as published formulæ support this statement, I will take it as a fair basis of calculation.

Thus we find that a pint of essence would make 83 gallons of syrup, and as a volume of this usually makes ten volumes of lemonade (Parrish), the quantity of lead found would be distributed over 830 gallons, or 13,280 ordinary half-pint bottles!

I next cut open the copper and examined the alloy which lined it. It contained 81·03 per cent. of tin, and therefore a maximum of certainly not more than 19 per cent. of lead.

Looking at these figures, one can scarcely avoid the conclusion that even were the lining of the copper lead alone, and even were the contents of a partly emptied copper exposed to atmospheric oxidation, which are the worst conditions I can suppose probable, the quantity of lead which could be thus introduced into lemonade would still be absolutely unimportant, and for my own part I cannot wonder that Mr. Umney should feel a doubt as to whether the statement was really made in earnest.

Two other points in Dr. Macadam's paper I shall shortly dismiss. He seems, if I have read rightly, to account for finding more lead in lemonade than in other aërated waters by the solvent action of the acid and saccharine liquid upon leaden vessels or pipes. He certainly does not directly say so, but if this be not the view he takes, the experiments upon the solvent action of lemonade upon lead have no significance. All who are practically conversant with the subject will understand me at once and see (what Dr. Macadam himself must well know) that as the syrup is only mixed with the aërated water *in the bottles*, its previous contact with lead could only arise from the grossest ignorance or carelessness.

Again I must, on behalf of all who value accuracy in chemical work, enter a protest against the serious setting forth of the indications of a colour test, such as that described, as worthy of the slightest confidence in a case like this. Several commonly occurring metals, other than lead, give coloured precipitates in acid solution with hydrogen sulphide.

The analyst suspects the presence of lead in a water; he makes a standard lead solution, applies his colour test to this, and to the suspected water, and reads the result as indicating so much lead. There is no reason whatever, beyond a preconceived opinion, why a standard *copper* or *silver* solution should not be used, and the result read as copper or silver. *Dilettante* chemistry is a pretty amusement enough, but it may be as well not to import it into such serious matters as charges of lead contamination involve.

I cannot think, however, that a quantitative colour test for lead will gain much favour, because perhaps the first time that it is relied upon as good chemistry or fair evidence, it may be demonstrated beyond doubt that it is neither one or the other, and in that case I am not aware that there is any especial ægis for sheltering the analyst from the consequences.

SOME PHYSICAL PROPERTIES OF QUININE.*

BY JULES REGNAULD.

Several chemists have during recent years published the results of their experiments upon the solubility of the salts of quinine, and they have specially occupied themselves with the substitution of the ordinary sulphate of quinine by a compound more soluble in water and better adapted for hypodermic use. The author proposes to test the correctness of the frequently discordant statements by means of well-defined salts prepared by himself from perfectly pure quinine. In the present preliminary note he treats of the solubility of the free alkaloid in water, alcohol, chloroform and sulphuric ether.

Solubility in Water.—Pelletier and Caventou, in their 'Analyse chimique des Quinquinas,' say simply, "Boiling water dissolves about 0·005 of quinine; cold water dissolves still less." From this it might be inferred that the solubility of quinine in water is pretty considerable; for, calculating according to the coefficient 0·005, one gram of quinine would dissolve in 200 grams of boiling water, and would require a larger, but undetermined, quantity of cold water. The greater portion of French standard treatises give different numbers, but unfortunately do not indicate their origin. The disagreement may be illustrated by the following examples:—

Quantity of Water required to Dissolve one gram of Quinine.

According to	At + 15° C.	At 100° C.
Dumas	——	200 grams.
Gerhardt	350 grams	400 „
Pelouze and Frémy	400 „	150 „
Wurtz	400 „	350 „
	At + 19° C.	
Berthelot	480 „	200 „

According to the same authors one gram of ordinary sulphate of quinine, $(C_{20}H_{24}N_2O_2)_2H_2SO_4$, requires about 750 grams of water (the author has found about 755) at 15° C. to dissolve it. From which it would result that an aqueous solution of quinine upon being neutralized by sulphuric acid, throws down, under the form of a deposit of insoluble sulphate, nearly half the alkaloid it contained: an inference manifestly incorrect. In fact, the figure

* *Journal de Pharmacie et de Chimie* [4], vol. xxi., p. 9.

given for the solubility of quinine in water by Pelletier and Caventou, and other French chemists, is exaggerated.

Dragendorff, in his 'Toxicologie,' represents the solubility of quinine in water as 1 in 1667; this number, though widely differing from the preceding, is still, according to the author's experiments, considerably beyond the true one. Three experiments were made by him with pure quinine, from which all traces of the other cinchona alkaloids had been carefully removed. This quinine was anhydrous, and presented the appearance of vitreous, amorphous, completely colourless and transparent scales. Finely pulverised in a glass mortar and then agitated during twenty-four hours with a large excess of pure distilled water, previously made to boil, it yielded a solution which after being kept during two hours at a temperature of 15° C., gave the following results:—

	Saturated Solution at 15° C.	Pure Quinine dried at 110° C.
	gr.	gr.
1st Experiment .	49·8278	0·025
2nd " . .	49·9780	0·024
3rd " . .	49·6950	0·025

These figures give for each 100 grams of saturated solution at 15° C.—

	Pure Quinine dried at + 110° C.
	gr.
1st Experiment	0·0501
2nd "	0·0480
3rd "	0·0503

Or a mean of 0·0494 gram of quinine in each 100 grams of solution; from which the author concludes that the coefficient of solubility at that temperature is 1 in 2024; or that one gram of pure quinine requires for its perfect solution at 15° C. rather more than two litres of distilled water.

The solubility is considerably increased at 100° C., as stated by most authors, and as is shown by the following experiments:—

	Water saturated at 100° C.	Pure Quinine dried at 110° C.
	gr.	gr.
1st Experiment .	64·5430	0·0870
2nd " .	65·5265	0·0840

Or a mean for each 100 grams of 0·1314 gram; from whence the author concludes that the coefficient of solubility of quinine in water at 100° C. is 1 in 760. Therefore water saturated with quinine at 100° C. deposits in cooling to 15° C. nearly two-thirds of the alkaloid originally dissolved.

Solubility in Alcohol.—The author used absolutely pure and anhydrous ethylic alcohol. One carefully conducted experiment gave a result so nearly concordant with what is stated in chemical treatises that it was not repeated.

Absolute alcohol saturated at 15° C.	Quinine dried at 110° C.
gr.	gr.
41·454	19·428

This is equal to 46·866 grams to 100 grams of solution, and the coefficient of solubility at 15° C. would be 1 in 1·133; in other words, 1 gram of pure quinine will dissolve in 1·133 gram of absolute alcohol at 15° C. Several chemists have mentioned the great solubility of quinine in alcohol. Dragendorff and Wurtz have it as 1 in 2, which is too low. The difference, however, probably depends upon a slightly hydrated alcohol having been used, for the solubility of quinine in alcohol decreases rapidly with the smallest addition of water.

Solubility in Chloroform.—100 grams of chloroform saturated at 15° C. gave 34·177 grams of quinine dried at 110° C., being equal to 1 in 1·926. This number is substantially in agreement with Pettenkofer's statement of 55 per cent., or 1 in 1·801. The coefficient 1 in 6·58, corresponding to 15·2 per cent. (Schlimpest), mentioned by Dragendorff, is evidently erroneous.

Solubility in Sulphuric Ether.—The ether used in these experiments was entirely free from aldehyde, alcohol, and water.

	Ether saturated at 15° C.	Quinine dried at 110° C.
	gr.	gr.
1st Experiment. .	32·3545	1·3990
2nd " .	18·6590	0·7965

Or a mean equal to 4·2314 of quinine to each 100 grams of solution. From which the author concludes that the coefficient of quinine in pure sulphuric ether at 15° is 1 in 22·632. This value is very different from that indicated by Dragendorff, who, according to Pettenkofer, supposes that 100 grams of ether dissolve 1·66 grams of quinine, or equal to 1 in 60, instead of 1 in 22.

Observations upon Aqueous Solution of Quinine.—The determination of the exact composition of the aqueous solution afforded the author opportunities for making numerous experiments upon some of the reactions of this alkaloid. The solution of 1 part in 2000 is bitter, and presents very clearly the emerald green coloration under the influence of chlorine and ammonia. Gallo-tannic acid causes an abundant precipitate. By means of mixtures consisting of definite proportions of this solution and distilled water the author ascertained that it is necessary to dilute one part of this solution of 1 in 2000 with ten parts of distilled water before the opalescence resulting from the formation of the tannate ceases to be visible in the sunlight, gathered in the focus of a convergent lens; 1 part in 20,000 is therefore the extreme limit of the sensitiveness of this reagent. This experiment shows that the solubility at a temperature between 10° C. and 20° C. is extremely slight, and that some statements that have been made upon this point are incorrect.

The fluorescence of the aqueous solution of 1 part of pure quinine in 2000 is almost invisible if the solution be examined in the direct sunlight. It is, however, perceptible up to an extreme limit of 1 in 20,000, if according to the method proposed by Stokes,* the rays converging from a lens or a concave metallic mirror be thrown upon it.

It is known that the presence of an excess of sulphuric acid increases the fluorescent power of quinine, and the author has found that this singular influence renders the solution of 1 in 20,000 twenty times more energetic. In fact, he has found that a solution of 1 part of quinine in 500,000 of water, when sulphuric acid has been added, possesses still a visible fluorescence, which is instantly destroyed upon the addition of hydrochloric acid, as stated by Stokes.†

From the fact above stated the author deduces the following propositions:—

(1). The solubility of quinine in water is at 15° C., 1 in 2,024, and at 100° C., 1 in 760; in absolute alcohol, at 15° C., 1 in 1,133; in chloroform,

* *Philosophical Transactions*, 1852, p. 463. † *Loc. cit.*

at 15° C., 1 in 1,926; in pure sulphuric ether, at 15° C., 1 in 22,632.

(2). The solubility of tannate of quinine in water is below 1 in 20,000.

(3). The fluorescent power of quinine becomes twenty times more energetic under the influence of an excess of sulphuric acid.

(4). By means of this exalted fluorescence, it is possible to recognize the presence of the alkaloid in a solution containing quinine only in the proportion of one part in five hundred thousand; a degree rather beyond that stated by Flückiger who recommends this reaction. The author finds it to surpass in delicacy, in the ratio of 5 to 4, the opalescence caused by the double iodide of mercury and potassium, which however furnishes no clue as to the nature of the alkaloid of which it reveals the existence.

ON SOME SUBSTITUTIONS.*

BY JOHN M. MAISCH.

Agaric, or *White Agaric*, is a drug which was formerly much more frequently employed than at present, but is still occasionally used in the United States, particularly in domestic medicine, and mainly as an ingredient in several bitters, which, among a portion of the German population, enjoy some popularity. The drug consists of the pileus, or cap of a fungus, named *Polyporus officinalis*, Fries, s. *Polyp. laricis*, Roques, s. *Boletus laricis*, Jacquin, s. *Bol. officinalis*, Villars, s. *Bol. purgans*, Persoon. It occurs in the market in irregular masses of the size of a fist and larger, is occasionally semilunar in shape, or resembles the section of a cone. It is of a white colour, light and friable, nearly inodorous, and possesses a taste which is at first sweetish, but soon becomes bitter and acrid.

Recently a sample of a so-called white agaric, which had been obtained in New York, was sent to me; it was in the form of a coarse white powder, intermixed with some larger, irregular white pieces, none of which exceeded a quarter of an inch in length or thickness, but, on superficial examination, possessed the physical characters of true agaric. The powder was of a sweetish, subsequently bitter, acrid taste, which, however, was much less marked than in the genuine drug; the larger pieces, freed from the adhering dust, were nearly insipid and entirely devoid of bitterness. A section placed under the microscope showed it to consist of the peculiar filamentous cells of the fungi; but on searching a number of works on materia medica, I found no adulteration or substitution mentioned, except by Wiggers, who states that agaric is occasionally mixed with pieces of *Polyporus igniarius*, Fries, made to resemble agaric by covering it with the powder of the latter. The substance in question, however, is not derived from a *Polyporus*, which genus is characterized by having the hymenium or gills concrete with the pileus or cap, and consisting of subrotund pores.

Some of the pieces have fragments of lamellæ still attached, showing the substance in question to be most probably the cap of a species of *Agaricus*, from which the lamellate gills have been almost completely removed, and which was afterwards broken into small pieces and mixed with some powder of the larch agaric, to impart a bitter taste. The substitution can easily be detected by examining some of the larger pieces in the manner indicated above.

Gossypii radicis Cortex of the U.S. Pharmacopœia, is the bark of the root of the cultivated species of *Gossypium*. The woody, conical, nearly simple root of the cultivated cotton plant is covered with a thin bark, about half a line to one line in thickness, rarely thicker. Externally, the bark is of a brownish-yellow colour, with larger irregular patches of a brownish-orange, caused by the abrasion of the outer layer of cork, and smaller ones more scattered, of a nearly black colour. The yellowish portion has a slight satiny lustre, the other parts are dull. The thin, corky layer which adheres well to the bast layer, forms shallow longitudinal ridges, often becoming confluent into narrow, elongated meshes. Suberous warts or their scars are scattered over the surface, at first circular in shape, ultimately forming short transverse, black lines. The inner surface is of a whitish, or reddish-white colour, a silky lustre, and finely but, to the naked eye, distinctly striate in a longitudinal direction. A pocket lens reveals these striæ as thin, medullary rays penetrating into the bark. The bast fibres are long and tough, and arranged in tangential rows, on account of which the inner bark may be separated into very thin, almost transparent layers without difficulty. The bark is without odour; the bast possesses scarcely an acrid taste; the corky layer is in the main rather feebly astringent.

Some months ago, in one of our wholesale stores, I met with a so-called cotton-root bark, which had been obtained from the State of Georgia, and which is so entirely different from the root bark of our cultivated *Gossypium*, as to leave no doubt whatever in regard to its origin from a different plant. The bark is in quills or curved pieces, several inches to a foot or more in length, and one-eighth to one-fourth inch in thickness, inodorous, of a slight astringent, afterwards bitterish and distinctly acrid taste; pale brown to rust-brown throughout in colour, and destitute of silky lustre, except the bast fibres upon a fresh fracture. The exterior surface is deep brown, the younger bark with shallow, longitudinal suberous ridges, the older bark with the soft cork more or less fissured, and exfoliating in small patches. The interior surface is of a dark brown or blackish-brown colour, and striate by the rather coarse bast fibres. The bark breaks transversely with little difficulty, and exhibits a coarse, splintery fracture from the numerous bast fibres, which are disposed in tangential rows; the inner bark separates in the same direction in rather thick layers. Some of the coarser pieces of bark are found with a clayey earth adhering in the grooves and bends.

The characters described are, with very insignificant variations, observed in the bark of the root of cotton plants, which some years ago were furnished me from several varieties grown in four or five of our Southern States, and for which I am indebted to the kindness of Dr. Robert Battey, of Rome, Ga., and Mr. Gallagher, of Washington, North Carolina.

It will be observed that the description agrees in several important points with the characteristics of mezereon bark, to which cotton-root bark bears a close resemblance, if colour and taste are not considered; the thin, ribbon-like appearance, the silky lustre of the internal surface, the transverse scars of suberous warts and the toughness of the bast fibres are common to both.*

What is the origin of this bark? It can scarcely be doubted that it is derived from the root of a tree, and it is not unlikely that it must be referred to one or more species of *Populus*, several of which are popularly known as *cotton-wood*, on account of the cotton-like filaments found in the fruit. This name is more particularly applied to the following three species: *Populus angulata*, Aiton, the western cotton-tree which is found from Pennsylvania to Wisconsin, and further southward; *Pop. monilifera*, Aiton, cotton-wood or necklace-poplar, from Western Vermont to Illinois and southwestward to Louisiana; *Pop. hetero-*

* *American Journal of Pharmacy* for January.

* After the above was in type, I have received, through the kindness of Dr. A. W. Miller, a sample of cotton-root bark collected by Wallace Bros. and Stephenson, of Statesville, North Carolina. This agrees in every respect with my cotton-root bark, except that it is more or less quilled, showing that it has been taken from the recently collected root, and dried without endeavouring to prevent its quilling; my bark was stripped from nearly dry roots and purposely kept in bands. I have not noticed any striking difference in the root-bark of the long and short staple cotton.

phylla, Lin., cotton-tree or downy-poplar, found in about the same localities, though rarer than the preceding in the New England States. The three species grow along river banks and in swampy localities, and it does not seem unlikely that one or all three yield at least a portion of the so-called cotton-root bark of commerce.

I am not aware that authentic specimens of the bark of *Gossypium* or of these species of *Populus* have been submitted to analysis, but as far as can be judged from the taste, and other sensible properties, I am inclined to the belief that at least a considerable portion of the commercial fluid extracts of cotton-root bark have *not* been made from the officinal *Gossypii radicis cortex*, but from this substitute.

The question then presents itself to which cotton-root bark must be ascribed the reputed emmenagogue properties, upon the strength of which *Gossypii radix* and afterwards *Gossypii radicis cortex* were admitted into the Pharmacopœia? The writer would be thankful to manufacturers of fluid extracts, to wholesale druggists, and particularly to physicians and pharmacists of the Southern States where *cotton-root bark* appears to be principally used, for authentic specimens of the plant and of its root, to which the medicinal properties are ascribed.

OS SEPIÆ.*

BY THOMAS S. WIEGAND, PH.G.

There are many among those who daily handle, and even sell the common cuttle-fish bone, as it is ordinarily termed, who would be quite surprised to learn that it is not a bone at all, at least in the same sense that the term bone is used in speaking of the vertebrate animals, the frameworks of whose bodies are bony. This "fish-bone," which is frequently found floating in the Mediterranean Sea, and in much greater quantity on the shores of Australia, is of an oblong oval shape, from three to ten inches long, and its breadth is about one-third of its length, hard upon its upper surface and edges, but soft on its lower side, both surfaces being convex; its specific gravity is about ·935. Its composition, though calcareous, is quite different from bone, being about 83 per cent. of carbonate of calcium, with some magnesia and common salt, and but little animal matter. The structure of the bone is quite peculiar; a fresh fracture, when examined, shows the layers of the calcium salt, supported by pillars of the same material, arranged in regular rows, likened by Wood, the naturalist, to a miniature giant's causeway.

The *Sepia officinalis*, for this is the title of the fish which furnishes the little songsters with their tiny grindstones whereon to whet their bills, belongs to the class mollusca and order Cephalopoda; this term alluding to the feet being attached close to the head. Its generic name *Sepia* is in consequence of the colour which it ejects when chased or angered. It is most commonly found on the Australian coast, though most of the commercial supply is derived from Europe.

The various names of great polypus, colossal cuttle-fish, gigantic squid, kraken, devil-fish, etc., will appear to be well deserved when some of their performances, for which very truthful observers vouch, are narrated. Montfort has described their habits fully, and shows them to be very dangerous and disgusting, even when so small as not to be dreaded for their size and strength; their activity and determination is very remarkable. The attack of one upon a ship, sailing from St. Malo, a seaport in France, is celebrated by a painting, hung up in the church of St. Thomas in that city, representing the vessel with the arms of the fish clasped about the masts and sides of the vessel which was only freed from the monster by the vigorous efforts of the crew in cutting away the encircling arms. The reader must remember, however, that the *Sepia officinalis* are not to be held answerable for these performances, they belong to other branches of the family; the smaller members are generally peacefully inclined, but when irritated they become exceedingly annoying to those who molest them. The rocks and coast of Madagascar is shunned by the natives who wish to swim on account of the rock squids fastening upon the persons of the swimmers with their suckers, if they venture too near the shore. One of the most recent accounts which appears well authenticated, is contained in a late number of the *London Spectator*, which tells of a cuttle-fish that appeared off the Newfoundland coast, in Conception Bay; some fishermen supposing it, from its size, to be a portion of a wreck, pulled out for it, and striking at it, they so enraged it that it raised its beaked head and encircled the boat with two of its slimy arms; instantly the men cut them away with their axes, and the fish, finding the fight too severe for him, sailed away, inking the sea for several hundred yards. The arm, which was of a pale pink colour and entirely cartilaginous, was preserved in St. John's Museum, and was found to measure nineteen feet; this report, so well authenticated, gives some show of truth to the marvellous story which Victor Hugo has so graphically depicted in his tale of the "Toilers of the Sea."

The use to which *Os sepiæ* is put in pharmacy proper is but trifling, it furnishing when levigated and dried, a very fine variety of carbonate of calcium, but is more generally employed in the fabrication of tooth powders, being the basis of Betton's dentifrice, and the cuttle-fish powder of Piesse, formulas for which are appended to this article.

There is one other product of the cuttle-fish which is used in the arts, a substance called sepia, a colouring matter of black colour, and when well prepared highly prized by artists. This substance is secreted by the fish from a bag or sack, which it can contract at will, and thus discharge some of the colouring matter into the surrounding water, and staining it for the purpose of preventing its enemies from seeing it so as to be able to pursue it.

A few words about the proper method of making the class of powders mentioned will perhaps be useful to the readers of the Journal. It is of the highest importance that the basis of all tooth powders should be so free from all sharp, gritty particles that there will be no danger of abrasion to the enamel of the teeth. This fineness, of course, is to be obtained only by careful pulverization and passing the powder through a sieve of fine bolting cloth, all the various materials being reduced to an equal degree of fineness. When colouring matter is to be added, and this generally is some shade of pink, the finest colour is obtained by washing the calcareous powder with a solution of carmine in aqua ammoniæ, and exposing the powder to the air until free from ammoniacal odour and moisture; to this prepared calcareous base the remaining powders are added, and the whole thoroughly incorporated by sifting together.

Betton's Dentifrice.

Take of—

Powdered cuttle-fish,	
,, orris root, each	4 pounds.
,, prepared chalk	1 ,,
Musk	8 grains.
Oil rose and lavender (Mitcham), each	48 drops.
Carmine, No. 40	2 drachms.
Aqua ammoniæ	5 fluid drachms.
Water	6 fluid ounces.

Rub the carmine with the aqua ammoniæ diluted with the water, and with this solution imbue the prepared chalk and powdered cuttle-fish bone. After the moisture has all disappeared, sift the orris root, perfumed with the essential oils, together with the coloured lime salts.

Piesse's Cuttle-Fish Powder.

Take of—

Powdered cuttle-fish	½ pound.
Precipitated carbonate of lime	1 ,,
Powdered orris root	½ ,,
Oil lemon	1 ounce.

* *American Journal of Pharmacy.*

Oil of neroli	½ ounce.
Carmine	⅓ drachm.
Aqua ammoniæ	2 fluid drachms.
Water	1½ fluid ounce.

Proceed as in former recipe.

THE VOLUMETRIC ESTIMATION OF IODIDE OF POTASSIUM.*

BY M. PERSONNE.

M. Personne has proposed a method of titration of iodide of potassium, which has been favourably reported upon by a committee of the French Academy of Medicine. It is based upon the following reaction: If solution of bichloride of mercury be added, a little at a time, to a solution of iodide of potassium, chloride of potassium is formed, together with a soluble compound of iodide of potassium and biniodide of mercury. But when one-half the iodide of potassium has been decomposed by the bichloride of mercury, the smallest further addition of that compound produces a persistent red precipitate. Thus, if to a solution of iodide of potassium, containing two-tenths of an equivalent or 33·20 grams per litre, ten cubic centimetres of a solution of bichloride of mercury, containing one-tenth of an equivalent or 13·55 grams per litre, be added, the red precipitate, which is at first formed, disappears, and is only reproduced upon the addition of a drop of the mercurial solution.

To prepare the test liquor 13·55 grams of bichloride of mercury and 8 or 10 grams of chloride of potassium or sodium are dissolved in 300 or 400 grams of distilled water; afterwards sufficient water is added to bring the quantity up to 1000 c.c. In another vessel 33·20 grams of the iodide of potassium to be tested are to be dissolved in sufficient distilled water to form a litre of solution. Ten c.c. of the solution of iodide of potassium are then placed in a glass vessel, and the mercurial solution is added drop by drop from a burette, graduated to tenths of a cubic centimetre, the mixture being continually shaken. The reaction is terminated when the mercurial solution produces a perceptibly red and persistent precipitate. It is only necessary then to read off from the burette the number of divisions employed to ascertain the richness of the iodide.

M. Personne has ascertained that the presence of carbonate, chloride, or bromide of potassium, is no obstacle to this application of volumetric analysis.

* *Repertoire de Pharmacie*, vol. ii., p. 737.

RIVERS POLLUTION COMMISSION.

The Rivers Pollution Commission, appointed in 1868 to inquire into the best means of preventing the pollution of rivers, having now completed its examination of the principal running waters of England and Scotland, has presented a fifth report. The report is rather lengthy, extending through fifty folio pages, and contains much interesting and valuable matter. The following is an abstract:—

"Former reports have described the evils arising from the discharge into river channels of town sewage; drainage waters from cotton, woollen, silk, flax, and jute works; from print and dye works; from tanneries, paper mills, and bleach works; from alkali, chemical, and soap works; from distilleries, starch, and sugar works, and from paraffin oil works. In every case the Commission has reported that efficient remedies exist and are available in sewage irrigation and intermittent filtration. But those remedies depend for their efficiency on the action of the air within the soil in oxidizing putrescible matters, and are applicable therefore only in cases where river pollution is due to the presence of matters of animal or vegetable origin. Many rivers and streams in the country, however, owe their polluted condition to mineral matters suspended in them; and in such cases it is by prevention rather than by cure, that a remedy must be sought. The Commission has accordingly recommended that the discharge of all solid refuse matters into the river channels be strictly forbidden under adequate penalties.

In the present Report the Commission deals with river pollution arising from mining operations, and from various kinds of industry connected with metals.

In describing the nature and extent of injury to rivers caused by mining operations, the following classification of sources of pollution has adopted:—(1) Pollution by collieries and coal-washing; (2) iron mines; (3) lead, zinc, copper, and arsenic mines; (4) tin mines; (5) manganese mines; (6) baryta mines; (7) china-clay works.

The first, second, fifth, and seventh classes contribute polluting matter which, though in many cases very unsightly, is, as a rule, not directly injurious to health, but the waste matters discharged into rivers from the third, fourth, and sixth are frequently of a character to produce injury to the health of persons using the water for domestic purposes, or of cattle grazing in fields which have been flooded by water so fouled. The polluting matters are nearly always in suspension and scarcely ever in solution; and as water polluted by mining refuse is almost invariably too muddy and repulsive in appearance to be used for drinking, it very rarely happens that injury to health arises in this way. Many of these refuse matters, however, are very destructive to fish.

1. *Pollution by Collieries and Coal-washing.*—Although coal is commonly termed a mineral, it undoubtedly consists chiefly of organic matter resulting from the very slow petrefaction of certain plants which flourished at a period of the earth's history inconceivably remote. The variations of quality are almost infinite, but all are commonly classified under the four following heads:—Cannel coal, bituminous coal, Welsh or smokeless coal, anthracite. The difference between these four descriptions is found to depend upon a difference in the chemical composition of the organic part of the coal, as is seen from the following analytical table:—

COMPOSITION OF VARIOUS KINDS OF COALS.

Constituents.	Cannel Coal.	Bituminous Coal.	Welsh Coal.	Anthracite.
Carbon ...	79·23	82·64	88·66	94·18
Hydrogen ...	6·08	5·31	4·63	2·99
Oxygen ...	7·24	5·69	1·03	·76
Nitrogen ...	1·18	1·35	1·43	·50
Sulphur ...	1·43	1·24	·33	·59
Ash (mineral matter)	4·84	3·77	3·92	·98
	100·00	100·00	100·00	100·00

The sulphur is present chiefly in the form of iron pyrites, a compound of sulphur, iron, and a variable but usually small proportion of arsenic. This compound is also rarely absent from the rocks in immediate contiguity to the coal; indeed it is sometimes found there in very large proportion. Until it is exposed to the air in the mine, iron pyrites is quite insoluble in water, but, in contact with atmospheric oxygen, it undergoes a slow oxidation and becomes transformed into sulphate of iron, which readily dissolves in water. It thus happens that the water discharged from those mines in which iron pyrites abounds is often much polluted by sulphate of iron. Such water is recognized by becoming turbid on exposure to the air and depositing an orange-yellow ochrey sediment of basic persulphate of iron, which adheres to and colours rocks or stones over which the polluted water flows. Water so contaminated is very fatal to fish, because the transformation of the protosulphate into persulphate of iron is effected, like that of the original iron pyrites into protosulphate of iron, by the absorption of oxygen. The water is thus deprived of its dissolved oxygen, which is absolutely necessary to fish life.

Analysis shows that whilst coal-pit waters are contaminated with but a small proportion of organic matter (organic carbon and organic nitrogen), they are occasionally acid, and frequently contain a considerable proportion of iron. The metal is in the state of carbonate in the water pumped from the Rainton meadow colliery, but it generally exists in the condition of protosulphate; both compounds are very fatal to fish, and may be injurious to cattle. This polluting agent also renders river water turbid and unsightly until the precipitated matter has had opportunity to subside. After subsidence, however, the river water is often considerably purified by the precipitation of a portion of its dissolved organic constituents.

The effects of ferruginous coal pit water are, therefore, partly deleterious, and (in the case of already polluted rivers) partly beneficial. But vast volumes of non-ferruginous or but slightly ferruginous water are pumped from collieries and discharged into rivers with unmitigated benefit to the latter. Colliery water is indeed occasionally sufficiently pure to be used for all domestic purposes.

Another pollution of water by collieries is that which arises from coal-washing, a process which has assumed important dimensions during the past ten years. In addition to the large masses or "cobs," and the smaller fragments or "nuts," there is always a considerable percentage of coal raised from the pit in the form of "slack," or even dust, mixed with the shale which is commonly found interstratified with coal. This latter material was, to a great extent, formerly regarded as waste; it was sometimes "tipped" into any convenient watercourse, but more frequently it was slowly burnt in vast heaps at the pit's mouth. Attempts to utilize this small coal, when it was of a bituminous nature, by coking it in ovens, and thus transforming it into coherent masses, failed on account of the large proportion of shale and of iron pyrites with which it was mixed. Coal has a much lower specific gravity than either shale or pyrites, and it was found that if the refuse material was placed in a stream of water, the coaly matter was carried forward by the stream whilst the shale and pyrites were left behind. The principle here involved is applied in a variety of ways; sometimes the refuse coal is placed upon large sieves of wire or perforated zinc, through which a stream of water is forced upwards in a succession of powerful pulses by the action of a steam pump. The coal is thus carried to the surface, and is washed off, or can be scraped off, from the shale below. The water after use is made to run through settling pits in which a considerable quantity of valuable coal dust is deposited, and after the water has become very black and turbid, it is run off, to the fouling of any stream into which it may run.

Vast quantities of refuse are piled upon the banks of the streams, with the obvious purpose of getting rid of it during floods, and thus rivers are silted up and caused to overflow their banks, grievously injuring the neighbouring meadows by covering them with coal dust, which kills the grass. Streams are also sometimes seriously polluted by arsenic derived from the pyrites of the coal.

2. *Pollution by Iron Mines.*—In iron mining there are no operations requiring the use of water. The ore is sold as it is raised from the pit, but the water discharged from the mines is usually contaminated by the trampling of the men in the passages underground. The pollution of water by iron mining arises therefore almost exclusively from matter in suspension, and as the suspended material is chiefly peroxide of iron, and not in any way injurious to health, this form of river pollution may be regarded as of comparatively little importance.

3. *Pollution by Lead, Copper, Zinc, and Arsenic Mines.*—Of all forms of mining industry carried on in this country, lead mining is the one which causes the most serious pollution of rivers. This arises not only from the essentially poisonous character of the ores themselves, but also, and chiefly, from the elaborate treatment, involving the use of large volumes of water, which these ores require before they are ready for the market. The lead ore raised from British mines is almost exclusively galena (sulphuret of lead).

Lead	86·6
Sulphur	13·4
	100·0

With the exception of the mines of Leadhills in Scotland, where a considerable proportion of the ore is phosphate of lead, all the lead mines visited yield only galena. In several of these mines, however, the occurrence of small quantities of carbonate of lead was noticed, which, being a virulent poison and not capable of profitable extraction for the market, plays, in all probability, a conspicuous part in the injury to cattle which is alleged to arise on the banks of streams polluted by the waste from lead mines.

Galena is met with in masses or nests, which are sometimes lenticular and sometimes nearly globular in shape; it also occurs still more frequently in lodes or veins. In almost all cases it is found deposited upon or embedded in a crystalline matrix, which usually consists of quartz, fluor spar, sulphate of baryta, or more rarely, carbonate of baryta. The galena and its crystalline matrix are found chiefly in the most ancient stratified rocks of the transition series. The proportion of lead ore in the crystalline matrix, as well as the comparative amount of metalliferous material to waste rock, varies excessively in different mines, and not unfrequently exercises an important influence upon the comparative pollution of the neighbouring streams, by producing in some cases but a small proportion, in others a very large one, of waste material per ton of ore.

The orey stuff is first sorted by hand into waste rock and useful lumps, the latter are then crushed either by chilled iron rollers or stamps. The next operation is technically known as "jigging;" it is performed by putting the crushed ore into horizontal sieves, which are then lowered into troughs of water and subjected to sudden jerks, communicated to them either by machinery or by levers worked by hand. The effect of these sudden movements is the subsidence of the galena to the bottom of the mass, and the accumulation of the rocky matrix near the surface; the latter, termed "skimpings," is removed by scrapers, and is sometimes deposited in heaps which attain a vast size; too frequently, however, the skimpings are tipped into the nearest stream.

The process of jigging is rarely successful in extracting the whole of the ore from the rocky matrix; indeed, where the operation is carelessly performed, or where the ore is disseminated in small particles throughout the mass of the rock, a very large proportion of ore is wasted. Such metalliferous skimpings usually find their way into the nearest watercourse, whence they are carried down the river, causing great destruction to fish and to poultry. In some cases, however, it is the practice to preserve skimpings, as far as practicable, from being carried away by rivers; and there can be no doubt that this consideration for the riparian proprietors below will receive its merited reward, since such skimpings, containing as little as 1¼ per cent. of galena, are now being profitably worked over again at the Wheal Wray mine, near Liskeard, in Cornwall.

The lower portion of the contents of the jigger sieve consists chiefly or entirely of galena, which is sometimes sufficiently pure for the market; more frequently, however, it requires to be again crushed or stamped, after which it is washed upon a slightly inclined plane; the heavy galena is left upon the plane, whilst the rocky matter, which is now reduced to the condition of mud, is carried along by the water to settling pits, where the coarser and more metalliferous portions are deposited, whilst the finer matters, which frequently contain, in addition to galena, carbonate of lead and blende or sulphuret of zinc, are allowed to escape into the nearest watercourse. The mud collected in the settling pits, technically called "slime pits," contains sufficient galena to render the further operations upon it remunerative. It is mixed with water so as to make it capable of flowing upon certain machines termed "buddles," the construction of which varies at different mines. The principle is, however, the same in all: the creamy mud is received upon a slightly inclined plane, which is sometimes stationary and sometimes revolving: here it is subjected to a comparatively sluggish stream of water, by which a more or less complete separation of the heavy galena from the lighter mud is effected. The latter is in some instances again run into slime pits to be once more "buddled," but more frequently it is allowed to flow directly into the next watercourse, although it often contains a large per-centage of galena. Such mud is distributed over the riverside land in time of flood, producing much mischief, if not absolute ruin, to the herbage, and occasionally poisoning cattle, if the latter be turned to graze upon the recently flooded lands.

In addition to galena, lead mines not unfrequently yield blende or sulphuret of zinc, copper pyrites, which is a double sulphuret of iron and copper, and mundic or arsenical pyrites, a compound of iron, arsenic, and sulphur. Of these, the first and last are not unfrequently disregarded by the miner; the blende being washed away with the waste slimes from the buddles, and the mundic being either thrown into the nearest watercourse or stacked in immense heaps, where by its gradual decomposition it yields, after rain, an arsenical drainage. Both blende and mundic contribute, therefore, in an important degree to river pollution; but copper pyrites is too valuable to be thus wasted, and its specific gravity is too low to allow of its being separated from its rocky matrix by washing. It is, therefore, picked out by hand, and does not, after its removal from the mine, pollute running water. Copper pyrites is, however, subject to slow oxidation by which some of it is converted, in the mine, into the sulphates of copper and iron which dissolve in the underground waters and reach the surface by pumps or adits. But even in this case the copper is only rarely allowed to escape into rivers, being precipitated by scraps of old iron.

At the Devon Great Consols the water pumped from the mine contains, besides arsenious acid and sulphate of iron, a proportion of sulphate of copper so considerable as to render the extraction of the metal remunerative. The water is first filtered through sand, by which an ochreous deposit, consisting of basic suphate of iron, is separated. The filtered water is then brought into intimate and prolonged contact with refuse scraps of iron. The copper in the sulphate of copper thus becomes replaced by iron, but the contact with scrap iron requires frequent repetition before the last traces of copper are removed from solution. By this method copper in a pulverulent or spongy condition, and of a high degree of purity, is obtained, whilst the polluting character of the mine water is very greatly mitigated The effluent water from this mine was reasonably free from all objectionable matter, except arsenic. Although the drainage is not discharged directly into the river, but is first mixed with a very large volume of water, the actual discharge from this mine into the *Tamar* was found to contain no less than ·6 part of arsenic in 100,000 parts of water, the standard of the commission permitting only ·05 part in 100,000 parts of water. The mundic or arsenical pyrites is utilized for the manufacture of arsenious acid. It is roasted in a current of air, and converted into marketable arsenious acid or white arsenic, of which, at the time of the visit of the Commission, as much as 165 tons, sometimes rising to 200 tons per month, was being sold. It is a startling reflection that, even at the lower rate of sale, there leaves this single mine every month an amount of white arsenic competent to destroy the lives of more than 500,000,000 of human beings. Stored in its warehouses, ready packed for sale, was seen a quantity of white arsenic, probably sufficient to destroy every living animal upon the face of the earth. It is, perhaps, still more startling to reflect that there is at present no efficient law to prevent many fold this amount of this deadly material from being cast monthly into the rivers and watercourses of this country; not, it is true, to expend its poisonous energy at once, for the mundic is insoluble in water, but, by its slow decomposition, to render rivers so treated poisonous and uninhabitable by fish for many generations.

4. *Pollution by Tin Mines.*—Tin occurs in nature both as sulphuret and oxide, but it is the latter one only, commonly called "tin stone," which interests the miner. This tin stone is hard, and nearly seven times as heavy as water. In colour it varies from grey to yellow, red, brown, and black. The Cornish ore occurs sometimes in veins or nodular masses, and sometimes disseminated throughout porphyritic rock or alluvial deposits. It is frequently associated with a large amount of friable peroxide of iron, which communicates to the effluent water from the dressing floors a dark red tint. Copper pyrites is often found along with tin in the same mine, the copper being usually nearer to and the tin further from the surface. It is, therefore, no uncommon thing for a Cornish copper mine to be gradually transformed into a tin mine, to the great enrichment of the adventurers.

The treatment of the tin ore varies at different mines, but the principle employed is the same in all; the tin stone with more or less of its rocky matrix is stamped in water to fine powder under large wooden pestles shod with iron; and the tin stone is then separated from the refuse slime by the action of water upon the mixed materials which possess widely divergent specific gravities. The effluent water from tin mines is polluting only by reason of matters in suspension. Amongst numerous samples analysed there was not one which even approached the transgression of any of the Commission's proposed standards relating to dissolved matters; indeed in most cases, mere subsidence leaves the supernatant water much purer than the average of potable water supplied to towns, the only objectionable constituent in solution being arsenic, which is present, however, in but very small proportion. On the other hand, these waters grievously pollute and silt up the rivers into which they flow, by the suspended matters contained in them. Each 1,000,000 gallons of water issuing from the Dolcoath mine, for instance, carries with it more than 80 tons of suspended rubbish, 200 lbs. of which are metallic arsenic, equivalent to 264 lbs. of white arsenic. Nearly the whole of this suspended matter is easily deposited when the water is quiescent. None of the samples contained copper in solution or exhibited any marked acidity.

5. *Pollution by Manganese Mines.*—Peroxide of manganese is an important mineral used in alkali works for the manufacture of chloride of lime. It is rarely met with, however, in this country, and only one instance of river pollution arising from mines of this description is mentioned. At Chillaton near Tavistock, peroxide of manganese is found in large bunches in a siliceous and ferruginous rock known by the name of "capel." The ore on being brought to the surface is washed and sometimes crushed. There is a small quantity of ochre associated with the ore which imparts a strong pink tint to the water issuing from the washing apparatus. The crushed peroxide of manganese is retained in catchpits, but the pink ochre, crushed siliceous matrix, and a considerable amount of the manganese ore find their way into a stream which, after a run of about five miles, joins the Tamar.

An unpolluted upland stream enters the mine and is used partly for power and partly for washing. It leaves the washing floors badly polluted with suspended matter, and contains also a small proportion of arsenic in solution. In the bed of the stream a considerable amount of mud is deposited. A sample of this mud contained 52·94 per cent. of siliceous rock insoluble in acids, 16·16 per cent. of peroxide of manganese, and a trace of tin. It can scarcely be doubted that so considerable a proportion of peroxide of manganese, worth about £6 per ton, would repay the expense of more elaborate subsidence than that employed at this mine.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, JANUARY 30, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

IRREGULAR MEDICAL PRACTICE.

ONLY a few weeks ago we ventured to congratulate our readers that there were indications of a healthy advance in opinion respecting the line of demarcation which should divide the doctor and the druggist. It is, therefore, with very much regret that, after so short an interval, we record this week a case in which that line has been ignored and overstepped, and the regret is enhanced by the fact that the person whose conduct is challenged is a registered chemist and druggist.

The main portion of the evidence given during the two days' inquest at Redruth, briefly reported at p. 617, was intended to clear up the points whether a club doctor, who found unexpectedly that his instructions respecting the treatment of a patient were being set aside in favour of those of another person, was justified in retiring from the case, and whether the treatment of either or both prescribers contributed towards the death of that patient. Neither the question of etiquette nor that of practice can be discussed in these pages; on neither do we assume to offer an opinion. When such disputes arise medical gentlemen have their own tribunals to which they can carry their grievances, and the freedom with which they have recourse to them seems to imply that they find them sufficient. But we remain quite within our province when we express an opinion—and that a very decided one—that the second person called in had no right to meddle with the case at all. For the fact that Dr. ROWE's name does not occur on the Medical Register, and does occur on the Register of Chemists and Druggists, warrants us in inferring that he possesses no legal qualification for carrying on medical practice in Great Britain. In our opinion, therefore, the—in this respect—minor question as to whether Dr. ROWE had a right, without consultation, to alter the treatment of the medical man originally in charge of the case, is decided by the more comprehensive fact that he did wrongly in interfering and prescribing in the case at all. And we quite agree with Mr. HITCHEN in the surprise that Dr. ROWE should take such a case, since he was not legally qualified to treat it.

Of course we are aware that it does not fall to the lot of pharmacists to carry out the provisions of the Medical Act, notwithstanding that this has been roundly asserted on at least one occasion in a medical journal. If the Medical Council feel unable or unwilling to enforce the penal sections the Act in this respect must remain a dead letter. But there can be little doubt that the true interest of the pharmaceutical body will be promoted by every individual member of it acting as far as possible in accordance with the spirit of that Act, and refraining from trespassing upon the ground sacred to medical men. And it is in this that we find our justification for condemning the conduct of Dr. ROWE, that he has acted antagonistically to the welfare of the body of which he is a member.

There is another occasion for regret in connection with this case, which may however be due to the officiousness or ignorance of a reporter. In one newspaper report which has reached us the words "Member of the Pharmaceutical Society" are appended to Dr. ROWE's name in a manner very suggestive of the title being intended to do duty in the absence of a medical qualification. For the reason before given, that it was possibly the result of an accident, we refrain from saying more than that the introduction of the title was most inopportune; for although Dr. ROWE is at present a Member of the Pharmaceutical Society, nothing could be more opposed to the policy hitherto advocated by the Society than his conduct as described in the evidence given at the inquest on JAMES CARKEEK.

TAXES ON PHARMACEUTICAL SPECIALITIES

HOW to impose taxes in a manner that shall be least irritable to the taxed is a study that has been carried to great perfection by British financiers, but they have hardly yet arrived at the pitch of consulting their intended victims as to the most agreeable way of conducting the operation. In France, however, several propositions having been submitted to the National Assembly for the imposition of a tax upon pharmaceutical specialities and new and special remedies, the Government, in August last, applied to the Academy of Medicine, in which pharmacists are well represented, for assistance in framing a definition of such articles that would be satisfactory. The subject was entrusted by the Academy to the consideration of a Committee which has recently issued its Report.

The first and main difficulty encountered by the Committee lay in the great variety of articles that might be denominated pharmaceutical specialities or special remedies, ranging from an ordinary article of the Pharmacopœia, the preparation of which has become a special feature of a particular house, to articles of food recommended for remedial properties. But the Committee came to the conclusion that although many specialities have their origin in a desire to perfect the art of pharmacy, it is characteristic of them all that their preparation is carried on for the purposes of profit. Deploring that at the present these special medicines nearly everywhere take the place of normal medicine, and recognizing that this result has been brought about mainly by advertising, the Committee chose advertising as the distinguishing mark which would best indicate the taxable article.

But there are advertisings and advertisings, and although the puff direct would be easily recognized, the puff oblique might give rise to greater difficulties. The Committee evidently feared that an obtuse officer of revenue might fail to discriminate between the puff contained in the newspaper or handbill and that uttered in the course of scientific discussions, even such as might take place within the Academy walls. It therefore recommends that the latter class of advertisements should be specially exempted, but that, with this exception, all medicines advertised in the journals, by handbills, or circulars, or by any other method of giving them publicity, and all substances, however prepared, or of whatever composed, which are so advertised to possess medical properties, should be deemed pharmaceutical specialities, and liable to the tax.

Even after five months' labour the Committee has failed to obtain perfect acquiescence in its conclusions; for, although the report was adopted by the Academy of Medicine, it has been sharply criticized by pharmacists outside. A writer in the *Répertoire de Pharmacie* suggests that the Committee having recognized the difficulties of its task, might have gone a little further with advantage and pronounced it impracticable. He also points out that the quotation of such an article as cod-liver oil in an ordinary trade list would bring it within the Committee's elastic definition of being advertised. On the other hand, it is asserted that a considerable trade might be carried on in an article that would otherwise be fairly deemed a pharmaceutical speciality without bringing it within the proposed definition, provided that the advertising be limited to the form of scientific memoirs and discussions, and the reports of them.

There appears to be some plausibility in these objections; but it may be that the French Government will consider them to be but manifestations of "ignorant impatience of taxation" of any kind whatever. It is rather curious that, judging from a statement made at the last meeting of the Philadelphia College of Pharmacy, some of our American brethren are giving vent to a similar outburst of impatience, the provocation in their case being the conduct of the Excise officers in rummaging their stores in search of unstamped "patent medicines."

THE "MORNING TONIC" CASE.

It is stated that the magistrate will not give his decision in the case of the prosecution at Hull of a Chemist and Druggist for the sale of "Morning Tonic," until the 2nd of February.

At the next Evening Meeting of the Pharmaceutical Society, which will be held on Wednesday, February 3, Mr. F. Sutton will bring forward the subject of the Construction of an International Pharmacopœia. There will also be a paper read on a New Variety of Senna, by Mr. E. M. Holmes. The Chair will be taken at half-past Eight precisely.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

The annual entertainment was held on Friday, January 15th, 1875. There was a crowded meeting, and a good programme of readings, songs, and recitations, rendered the evening a very enjoyable one. Mr. Hester presided, and was supported by Messrs. Masters and Druce; the vice-chair being occupied by Mr. Osborne, supported by Mr. Wallis.

A special meeting of this Association was held on January 22nd, 1875. Mr. Hester presided. Mr. Druce (the Secretary), after reading the minutes of previous meetings, said that Mr. Sutton had sent the Association a quantity of prescriptions, and that in answer to their appeal a fair number of chemists in the town had become honorary members. He was very pleased to add that two of them had promised to read papers before the Association shortly.

Mr. Hester thought that the meeting should pass a vote of thanks to those chemists who had joined as honorary members, and the motion having been proved by Mr. Kemp, and seconded by Mr. Wallis, was unanimously carried.

Mr. Druce then read a paper on the English Cruciferæ, first describing the characteristics of plants of the order, dwelling particularly upon the uses they were put to, and their general wholesomeness. He then proceeded to show specimens of the greater portion of the order, describing their uses, the effects of cultivation upon them, their habitat, and other points of interest; as, for instance, the erratic occurrence of *Sisymbrium sophia*, which in 1873 he could not find in Northamptonshire; but in 1874 he found it not uncommonly in places as far distant as Daston and Higham Ferrers, Rothersthorpe and Brampton. *Brassica oleracea*, the origin of cultivated cabbage, cauliflowers, brocoli, etc., had been cultivated from very remote antiquity, the Greek poet attributing its origin to the circumstance that Zeus being troubled one day in an attempt to reconcile two conflicting oracles, perspired, the cabbage growing from that perspiration. The cabbage was probably first grown in England by the Saxons, who were so fond of it that they called February "Sprout Kale." The preparation of saurkraut in Germany was then described, and the peculiar growth of kohl rabbi, and the enormous size of the Jersey cow cabbage noticed. The mustards, *Sinapis alba* and *S. nigra*, with their principles, having been touched upon, Mr. Druce alluded to the falling away of the parenchyma in the leaves of the horseradish when young on dry soils, and the establishment for the last few years upon the Nene banks of *Lepidium draba*. He concluded his paper by saying that out of the 1600 species included in the order, some 60 or 70 of the Cruciferæ were found in England, and of these, perhaps, a dozen had been added to our Flora by long cultivation for food, ornament, or medicine. The order was not generally a favourite one, as with few exceptions the plants were not distinguished by striking beauty or odour; but to the pharmacist it could not fail to be interesting and suggestive. The formation of oil of mustard, the composition of oil of horseradish, the occurrence of iodine in water-cress, the colour in woad, the trimethylamine smell of *Brassica incana*, the seed coats of *Sinapis*, the geographical distribution of *Hutchinsia petrea*, the bulb-producing growth of *Dentaria*, were subjects which would take up much time before their wonders were exhausted.

After the usual vote of thanks the meeting adjourned.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSOCIATION.

The fifth general meeting of the session was held on the 20th January. Mr. John Currie, President, presided. In the course of the usual preliminary business donations were announced from The Glasgow Apothecaries' Company and Messrs. Frazer and Green, W. and R. Hatrick and Company, James Taylor, etc.; and several new members were enrolled. Arrangements were also completed for the annual festival (supper and ball), which will take place on the 3rd February.

Dr. Campbell Black was the lecturer of the evening, who chose for his subject, "Some Aspects of the Glasgow Medical Charities." Dr. Black reviewed, in a racy and interesting manner, the institution and progress of the various charitable dispensaries and infirmaries connected with the city, and pointed out what he considered some of the circumstances connected with them, more especially as affecting the retail drug trade. The address was listened to with attention, and at the close, on the motion of the chairman, Dr. Black was awarded a hearty vote of thanks. It is understood that Dr. Black leaves Glasgow for London very shortly.

Mr. Paul's motion for the admission of lady chemists and druggists as members of the Association, was lost by a large majority.

The Secretary (Mr. Fairlie) intimated the result of the special meeting of the trade on the question of prices and examinations. The price list committee were instructed to confer with the Edinburgh committee, and a committee was also appointed to draw up a memorial to the Council of the Pharmaceutical Society, drawing attention to the examination question.

BRIGHTON ASSOCIATION OF PHARMACY.

At an ordinary meeting of the above Association, held on Friday evening, the 22nd inst., W. D. Savage, Esq., J.P., in the chair, that gentlemen read the following paper:—

"At the opening of a session it has been usual to commence with a review of the work done in the past, and, when circumstances permit, to foreshadow the future; but on the present occasion a supper inaugurated the session, and except that some kind friends have promised to read papers, we have no systematic teaching or lectures to anticipate; the few assistants and apprentices in the town that can avail themselves of any aid the Association might render are insufficient to justify any great outlay. It seems to be a complaint general throughout the country that such associations are not, as a rule, prosperous. Some noteworthy exceptions do occur, where local talent and energy combine to ensure success; but, as a rule, after a few years of struggle such efforts as most towns can command become exhausted through want of time or appreciation by the young men, and die out. Several circumstances combine to produce such results. It may be that the young men will not unite to make efforts for themselves; but rather trust to a few of their employers to initiate and carry forward any movement, although it must, in the nature of it, be more for their advantage than it can possibly be for the masters'. Judging from past experience, the young men who have succeeded in passing their own examination, and are therefore most capable of conveying practical information to those who look forward anxiously to pass the minor and major, do not put in an appearance at our meetings. This is much to be regretted, but it is none the less true. Moreover, it happens in some cases that as the principals take an active part the assistants cannot leave business during their absence. In the new order of things it was only reasonable to expect a great effort would be made to meet the educational requirements of the Council, but I am afraid that some are calculating on spasmodic efforts for six weeks or two months in London, instead of the steady acquisition of knowledge so essential for permanent success. The Council of the Pharmaceutical Society are most willing to help all local associations that are capable of giving evidence of vitality and which show their anxiety by practical work to help themselves.

"Having said thus much as preliminary, I will now endeavour to interest my young friends at least in the following remarks in connection with the *Pharmacopœia*. In Nuremberg a young student, named Valerius Cordus, whilst on a short visit showed the results of his assiduity by producing a collection of medical recipes, which he had carefully collected from the works of the most eminent writers. The physicians of the city were so struck with the value of the selection that they urged him to print it for the benefit of the apothecaries, and having obtained for his work the sanction of the Senatus, the first known Pharmacopœia was published at Nuremberg in 1542. Previous to the publication of a Pharmacopœia, we are told that Avicenna and Serapion's work on 'Simples,' the 'Liber Servitoris,' the 'Antidotarum,' and similar works by different authors, arranged alphabetically, furnished such general information as could be obtained bearing on Pharmacy, or, as its name implies, 'Drugs.' In the early days of pharmacy, there were so many strange combinations of snails, woodlice, frogs, toads, puppy dogs, foxes, etc., etc., that the term pharmacy as now understood would scarcely apply; for in a comprehensive sense it means the department of natural science which treats of the collection, preparation, and preservation of medicines, and also the art of dispensing them according to the Pharmacopœia and the prescription of medical practitioners. In other words, 'Pharmaceutical Chemistry' and the Pharmacopœia consist of the materia medica, simple or compound, with characters and the tests for the determination of purity, together with directions for preparing articles of the materia medica and chemical compounds in accordance with approved prescriptions. Bearing in mind these characteristics, all civilised nations have national Pharmacopœias; those of the United States, France, and Germany are best known to us. In tracing the progress of pharmacy, we find that seventy-six years intervened between the date of the appearance of the Nuremberg Pharmacopœia and that of the first English one in 1618. We must not lose sight of the remarkable changes that have been effected since then by railways and the telegraph, which have brought nations into as near proximity now as Brighton was in those days to the metropolis. Subsequently we find that the next English Pharmacopœia followed in 1627, or nine years after; another edition followed in 1635, or eight years after; another in 1650; and then there was an interval of 27 years, or until 1697; then 24 years, to 1721; then another 25 years, to 1746. Then followed the longest interval, being 41 years, which brought the date up to 1787; then 22 years, to 1809. From this date shorter periods intervened; 1824, 1836, 1851, 1864, and 1867. So that if we compute the 14 editions in 249 years, we shall find an average of 18 years or nearly so (17y. $9\frac{6}{14}$m.) intervening betwixt each publication.

"It is not my intention to take a review of the different editions of the Pharmacopœia; it would occupy much more space and time than I can afford to give, at the same time would scarcely repay for the trouble. However, I shall make some selections so that we may be enabled to judge of the progress that has been made from time to time.

"In the first edition of 1618, after the introduction, follows an address to the candid reader, and a *brief* of His Majesty (James I.), assuring him (as all subsequent editions do) of the care and industry of the College of Physicians in compiling the work—that it is now perfect and will greatly tend to the public good. It requires that the apothecaries, to whom the book is addressed, shall in future abolish all uncertainty; that all medicines and medicinal receipts, the distillation of all waters and oils, and other extractions, be prepared according to the said book and according to the weights and measures that are or shall be therein limited, and not otherwise, under pain of the royal displeasure and the incurring of such penalties and punishment as may be inflicted for contempt of royal authority; and all majors, sheriffs, justices of the peace, constables, etc., are required to aid and assist in carrying out the law. Then follows the special privilege of printing and publishing the Pharmacopœia to John Marriot, of London. Any offender against this law was to pay a penalty of £5. Then follow the weights—of grains, scruples, drachms, ounces, and pounds (of course 12 oz.). Amongst the measures, a spoonful of syrup was to be ½ oz.; whilst the same quantity of water is ʒiij; a glass or cup, 1½ oz. Then comes *Hemina* ℥ix, or ¾ of a pint, a lb., and a sextarius or double heminos, ℥xviij. Then the gallon, or six sextarii, or 12 oz. short of our present gallon. In the order of publication follow a catalogue of simples, embracing 146 roots, 33 barks, 14 woods, 287 herbs, 81 flowers, 212 fruits and seeds, gums, juices, plants, animals, etc., etc., and it is curious to see the arrangement. For instance: five flowers, cordials; five herbs, emollient; four seeds, carminative, etc., etc. There are no less than 180 distilled waters, besides 26 compound waters with more or less spirit. A remarkable contrast is presented on endeavouring to compare the first Pharmacopœia with the last, and the most striking peculiarity will be observed in preparing 'the simples,' as the materia medica of 250 years ago was called. There were then no less than 62 syrups, and whilst some of the names are now familiar with us, the mode of preparation was very different. For instance: there was syrupus è papavere, minus compositus, which, besides the capsules of the black and white poppy, contained seminum lactucæ, and flor. violæ. Again, the same capsules, with maidenhair, liquorice, mallow, and quince seeds, formed the papavere magis compositus. Syr. papav. erratico was recent red poppies, lbiij; water, lbiv: sugar, lbiij. There was a syrup of roses and another of violets; also simple oxymel and oxymel of squills, differing in no essential from our present preparations. Syrupus augustanus vel de rhabarbaro was anything but rhubarb, there being besides a little rhubarb fifteen other articles in it. After these follow six robs, or inspissated juices with sugar, some lohochs—a preparation, as its name implies, to be licked up; 61 condita, or preserves; 53 conserves; some aromatic powders for electuaries. Amongst the powders I find pulvis ad scabiem, and it is satisfactory to find that amongst other things, our present useful friends, sulphur, nitre, and hellebore had a prominent place. A compound powder of senna, cream of tartar, cloves, cinnamon, etc., etc., was called pulvis sanctus, and pulvis sennæ was senna, cream of tartar, mace, ginger, etc. Electuaria are numerous. Lenitive electuary appears four times with different ingredients, amongst which are senna, rhubarb, rasins, and tamarinds. But amongst the preparations with sugar, honey, or treacle, is one extraordinary compound called 'antidotus magna,' with something like *one hundred and fifty simples,* a rival to the well-known 'mithridate.' Such a compound would, if placed on the examiners' table in Bloomsbury Square, puzzle the examiners as well as the examined. Hiera picra, of two hundred and fifty years ago, was composed of cinnamon, wood aloes, mastic, saffron, etc., but was in the form of an electuary. Amongst the surviving names of pills are —aloes and mastic, rhubarb, pil cochiæ, and assafœtida; but in no single instance the same as now. Take, for instance, the pilulæ de rhabarbaro: rhuharb, liquorice, mastic, hiera picra, etc., etc. Another peculiarity amongst the pills is 'laudanum,' containing ext. opii, castor, croci, etc., etc. So that the poor, asking as they sometimes do for liquid laudanum, are not so absurd as we sometimes think.

"There were only three preparations with white wine, viz., wormwood, antimony, and squills. With white wine vinegar there were six, the acet. destil. and acet. scillæ being amongst the number. There are nine recipes for decoctions, one of which is for decoc. sennæ, containing, besides senna and ginger, eight other articles, and one curious compound called 'lac vergineum,' consisting of crude alum, lytharge, and wine vinegar. Amongst the forty varieties of troches is a curious one, 'trochisci de vipera,' and the better to understand the value then supposed to be in the viper, Mr. J. Miller, in his new course of chemistry (1753), describes the method of distinguishing the true viper from the common snakes, and adds, 'We generally meet with the vipers skinned, gutted and dried; but the people who sell them are apt to mix snakes of the common kind among them; it is best to buy them alive, and see them skinned and prepared for drying at home.' Just imagine a pharmaceutical chemist receiving from the country a few of these venomous reptiles to skin for a strumous patient, as per ℞. The number of expressed oils from seeds is much more in agreement with what we now have than anything else, although of course there are many others that we know not now. There were other oils made from infusions and decoctions, but these for the most were from such vegetables as did not readily part with their oils, being first infused and then subject to the action of fire on an alembic. Sometimes we are told that it was necessary to add sea-salt, or even its acid spirit. In some preparations fixed oils were added to vegetables and pressed out. A simple oil of scorpions was, thirty scorpions to lbij, bitter oil of almonds. Amongst the recipes for compound oils is 'the blessed oil,' another the oil of Exeter, and also one of foxes. In the order of arrangement follow, ointments, plaisters, and cerates. Amongst the ointments are unguentum basilicon, majus and minus, with forty-five others. Thirty-eight plaisters then follow. Amongst them is the old well-known oxycrocium, a very different thing, however, from what some of us may recollect under that name. The succeeding pages of this Pharmacopœia of 1618 are occupied with some chemical oils and other great chemical preparations of iron, cream of tartar, antimonials, etc., etc. One cannot help being struck with the absence of *all* tinctures, with the old preparations, and the great complexity of what were called simples, which in the form of infusions and syrups were not always made with water, but sometimes contained white wine. There were no extracts at all analogous to what we now have; indeed I think we must all confess that there has been progressive improvements in Pharmacopœias, not only in their arrangements but in the definite character of the different preparations.

"As I have said before, I shall not attempt to review the successive editions of the Pharmacopœia; it would occupy too much time, and would scarcely repay the effort. However, it may perhaps be as well to show the progress made so early as thirty-two years after the first edition, passing two intermediate editions. Let us just glance at the one of 1650, as given in a copy of 1668. I find seven spirituous preparations and *ten* tinctures in the former; the only *name* familiar to us is sp. lavend. co., a very different compound, however, for besides lavender and santalum rubrum, it contains thirty other articles, some of which are now unknown in medicine. As it may be interesting I will give the names of the tinctures then ordered:—they were castor, celandine, saffron, strawberry, east arrow (*ononis*), sun-dew (*rosa solis*), water germander (*scordium*), treacle and verdigris. As you will perceive, only two, castor and saffron, are well known to us. The others like these are not simple tinctures, but are compounds supposed to have analogous effects, although in the case of the treacle I cannot trace any likeness. Besides treacle and other things, there is mithridatium, an article with forty-eight constituents. I should remark, by the way, that the 1618 Pharmacopœia is a large book, 12 in. by 7½ in., whilst the 1650 is a small pocket edition of 5 in. by 3¼ in.

"Again I will ask you to pass over a period of one hundred and fifty years, and consider with me the textbook of our trade one hundred years ago. It is more than that time, but, as in 1864, we enter upon a new era when the British Pharmacopœia was produced, it will be well to consider the editions of 1747 and 1787 as compared with 1851. The pretty pocket edition still continues, and presents a remarkable progress. The weights and measures are the same. The simple extracts are 12 altogether: 7 of them will be found in the Pharmacopœia of 1851, viz., gentian, liquorice, jalap, logwood, cucumber, bark and chamomiles. The only compound extract, extract of coloc. co., is essentially the same as now. The mineral dilute acids are recognized, and the alkalis (kali and natron), and the preparations of sulphur, antimony, iron, mercury, lead and tin; then follow distilled waters and no less than 17 spirits. The decoctions, of which there are 11, contain hartshorn, one for enemas, and one of mallows and chamomiles for fomentations. The mucilages are starch, gum and quince. The infusions are gentian, senna and roses. The wines are aloes, antimony, iron, ipecacuanha and rhubarb. Perhaps the most important progress after all is manifested in the tinctures, 37 in all; 33 of which re-appear in 1851. The 4 omitted are tinct. bals. peruv., tinct. rhei sx., galbani and savine co. It is somewhat remarkable that the Inland Revenue should now for the first time pounce upon one of our trade for selling bitters, simply because they are called 'morning tonic,' when I find that in 1747 tinct. amara was composed of gentian, orange-peel, cardamoms and proof spirit; and for 127 years this compound, or one very similar, has been sold without let or hindrance. It seems strange that the susceptibilities of the Excise should be so unexpectedly aroused, but I hope only to subside, with a conviction that the proper province of the druggist is the sale of tonics, and if any have infringed the rules of trade it is surely the publican, who takes such a portion of our trade, legitimately our inheritance. When the apothecaries in 1624 were accused by the grocers of usurping their trade by buying and selling all drugs and distilled waters (spirits), King James said, '*I do allow it*, that the grocers are only merchants and unskilled;' so I think the 'King Public' might now say the publicans are unskilled, whilst the chemists have the requisite knowledge: and at any rate I do trust that we shall all, as far as we can, avoid infringing the law. I must apologise for this digression. In the so-called mixtures were camphor, chalk, and musk, with milk of almonds and ammoniacum; musk is the only one withdrawn. Of fifteen syrups, three only are left out, viz., cloves, black currant, and raspberry. Out of nineteen formulæ for powders, eight only survive: pulv. aloes co., pulv. antimonialis, pulv. cretæ compositus, pulv. cretæ opio, pulv. ipecac. co., pulv. scammonii co., and pulv. tragacanth co. Of six recipes for pills, four only are retained, aloes, aloes and myrrh, blue pill, and squill. Amongst the curiosities of the London and Edinburgh Pharmacopœias of that time may be mentioned, crabs' claws (*chilæ cancrorum*), literally, the black tips of the common great sea crab; then follows crabs' eyes (*oculi cancrorum*). How they could have obtained that name seems a mystery, for they are said to be concretions (like small stones), found in the stomach of the cray fish, and as counterfeits, made of pipe-clay and chalk, were sometimes substituted, a means of testing them is supplied; for whilst vinegar or the stronger acids diluted, will entirely destroy the spurious articles, the genuine remain unaltered in shape, but become soft and transparent. They formed the basis of a powder as well as a lozenge. Another article of the Pharmacopœias of London and Edinburgh was millipedæ, *alias* wood lice, hog lice, slaters, once highly commended for suppression of urine, obstructions of the bowels, jaundice, etc. Millar says they are best prepared for medicinal use by being held over the steam of hot spirits of wine. One more illustration: bezoar, another of these animal concretions from the goat family. There were two kinds, *oriental* and *occidental*, the first was of the greatest value, and came from the East Indies; the Arabians considered it effective against poisons (alexipharmic), others as a sudorific, but as it was insoluble in the gastric juice we may safely question its virtues. Before leaving this subject I must advert to one other article, because it is sometimes met with in old works, and it is well to know what kermes, London and Edinburgh, is. My notion was that it was a metal, and to a certain extent I should be right, but the kermes of the Materia Medica of 1747 was a round grain about the size of a pea, which was found in Spain, Italy, and south of France, adhering to the branches of a tree, and full, when fresh, of small reddish ovula, or animalcules, of which they were the nidus. To preserve them, vinegar was sprinkled over them to prevent the exclusion of the ova and to kill such of the animals as were already hatched, otherwise the change into a winged insect would leave the grain an empty husk. Pills composed of kermes, etc., are said by Geoffroy to prevent miscarriage and to make a joyful mother. But I must now bid adieu to ancient pharmacy, and consider briefly the most important epoch in our pharmaceutical history. The difficulties which dispensers had up to this period to contend with were mainly due to the different Pharmacopœias of the London, Edinburgh, and Dublin Universities. To obviate this difficulty the Medical Act of 1858 was obtained, and eight English, five Scotch, and five Irish physicians, together with six nominated by the Privy Council, constituted the first executive of the British Pharmacopœia of 1864. To alter and assimilate the different preparations of the different countries was a task of considerable difficulty, involving much time and great labour, and when finished it was by no means perfect. The change from the troy to the avoirdupois weight occasioned much difficulty, as the ʒj and ℈j were abandoned—so that the lb., oz. and gr. were the only recognized weights. Although the symbols for measure were plain and distinct, as fld-oz., fld-dr., etc., few could be induced to adopt them. Who cared to represent half an oz. as $218\frac{1}{2}$ grs? The change was not an improvement. Amongst the chemical nomenclature we have our old friend calomel as hydrargyri subchloridum (1750, mercurius sublimatum dulcis), whilst its dangerous relation, sublimate, is called hydrargyri corrosivum sublimatum (1750, mercurius sublimatum corrosivum). These changes perplex, and are at all times unsatisfactory. As our chemical knowledge is constantly altering it is far better to have a definite fixed name than such frequent alterations. As the result of the joint labours, of the *excluded* articles 72 were from the E. P., 46 from the L. P., and 36 from the D. P. Comparing the B. P. with the L. P. of 1851, 51 new organic substances were introduced. The arrangement, having the materia medica in one division, and the preparations in another, caused a good deal of dissatisfaction. In one place you look for the process, and have to refer to another for characteristics and tests. One illustration will suffice. Ammoniæ acetatis liquor, in alphabetical arrangement, is found in page 15, whilst the method of making, under the head of liquor ammoniæ acetatis is found at page 267. This first effort of the combined wisdom of the three universities was doomed to an early and unregretted end, for in the next edition of 1867 more interest was manifested in obtaining public opinion, by submitting proof impressions to those willing and able to give an opinion, so that when suggestions likely to improve the work were offered, they were adopted before the final issue, and the result has proved the wisdom of the course adopted. Valuable suggestions from Mr. D. Hanbury, Mr. Haselden and others, were not lost sight of, and with the able co-operation of Dr. Redwood in the committee, a work was produced, that, although having still some faults, we may well be proud of. Subsequently we have added to the B. P. those new and well-recognized preparations which in the progress of events must be constantly cropping up, and will have to be provided for. I will not, however, trespass much longer on your time and patience; all recent events are so well known that it would be wearisome to dwell upon them. But I must just advert to the change of names again, especially in mercurials. We have to recognize calomel as *hydrargyri subchloridum* and sublimate as *hydrargyri perchloridum*. I do hope that our familiar friends may now be permitted to enjoy their new names for a long time to come. In taking a retrospective view of the changes that have occurred, one cannot help being struck with the old and popular names that have survived so long, such as pil cochiæ, hiera picra, milk of sulphur, lenitive electuary, paregoric, etc., etc. Curious enough is a recipe for *nepenthe*. Homer's nepenthe, by which Helen diverted the melancholy of those who entertained her, must have given rise to a preparation of bugloss, saffron, opium, etc., by the which others hoped to accomplish a like object.

Mr. Savage also exhibited two copies of Pharmacopœias, one 200 and another 100 years old.

Mr. Cornish proposed, and Mr. Haddock seconded a vote of thanks to Mr. Savage for his interesting paper, with a request that it be sent to the *Pharmaceutical Journal*, which was carried unanimously.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

The third meeting of the session was held December 15th, 1874, Mr. A. P. Brown in the chair. Professor Maisch, on behalf of Messrs. Kurlbaum and Co., presented two samples of crude material from which borax is prepared: tineal, from the East Indies, which is no longer used for refining in the United States, and Hayesine, called after the mineralogist, a native borate of calcium from Peru. Professor Remington, on behalf of Messrs. Powers and Weightman, presented a basket, consisting of a beautiful crystallization of copper sulphate, coated with dammar varnish, thus protecting the salt from atmospheric influences.

Mr. A. P. Brown stated that he had found the market supply of oils of Ceylon cinnamon adulterated with oils of sassafras and cloves. Several of the members present stated that they had noticed the same adulteration.

Professor Maisch read a paper by Mr. George W. Kennedy, upon the occurrence of arbutin in *Kalmia latifolia*, an Ericaceous plant, from which the following is an extract:—

"The genus takes its name in honour of Peter Kalm, a distinguished Swedish botanist. The *Kalmia latifolia* is known by the names of calico bush, mountain laurel, and spoonwood, the latter name being given because the Indians made spoons from the wood. It is an evergreen, and is found abundantly from Maine to Ohio and Kentucky, growing on hillsides and mountains, preferring damp soil; the leaves are mostly alternate, bright green on both sides, ovate-lanceolate or elliptical, tapering to each end, and tenaceous. It grows from four to twenty feet high, its growth being influenced by the locality; on level grounds and small hills it is scarcely ever found above ten feet high, whereas in mountainous regions it grows as high as twenty feet, presenting a tree-like appearance.

"The process adopted for the extraction of arbutin was that of Kawalier, and was conducted in the following manner: Three pounds of the fresh leaves were collected by the writer and carefully dried in a room, when they were found, upon reweighing, to have lost sixty-three per cent. The dried leaves were coarsely powdered and treated with boiling water for several hours, strained and expressed, and again treated in a similar manner. The mixed decoctions were precipitated with acetate of lead and filtered, the filtrate was then submitted to the action of sulphuretted hydrogen to remove all the lead; the liquid was then again filtered and evaporated to the consistence of a soft extract. The evaporation in the first experiment was carried too far, leaving a viscid, reddish-coloured mass, in which, after standing several days, no crystals of arbutin were perceptible. Another similar experiment was made, with the exception that the liquid, after being treated with acetate of lead and sulphuretted hydrogen, was not evaporated so much; this time the arbutin separated in crystals, repeated experiments giving the same satisfactory results. A few crystals were separated from the mass to which they were adhering and dissolved in water. The solution was made alkaline by ammonia as directed by Jungmann, and phosphomolybdic acid added, when immediately the beautiful blue colour characteristic of arbutin was produced. Quite a weak infusion of *Uva ursi* was at the same time made and tested as above, which gave the same blue colour. If an impure solution is examined, which with ammonia will make an orange colour, the phosphomolybdic acid added to this will change it to a bluish green. *Kalmia latifolia* does not contain arbutin so largely as *Uva ursi*; the yield from the mountain laurel was so small that I did not separate it from the adhering mass. The process of Kawalier is certainly a very good one as to simplicity of extraction, with the exception of acetate of lead, for which the basic salt may be substituted with advantage, to separate gum and colouring principles, the presence of which will retard the crystallization of the arbutin. Besides arbutin, the presence of gum, tannin, lime and iron were noticed incidentally."

Professor Maisch remarked that this paper was of much interest, and that he had himself suggested the prevalence of arbutin in many Ericaceous plants (*Am. Jour. Phar.*, 1874, p. 314). Professor Maisch also read a paper by himself on substitutions lately found in the market of agaric and *Gossypii radicis cortex* (see page 604).

This paper was received with much interest, general surprise being expressed that the cotton-root bark of commerce was of uncertain origin.

Mr. W. H. Walling said that during a sojourn in the South he had been told by physicians that it was the root of the cotton plant they used.

Mr. R. V. Mattison said he had prepared fluid extract of gossypium, and recently, in conversation with a manufacturer of fluid extracts, was shown a large bale of cotton-root, as being probably the root bark of a *Populus*.

Mr. E. M. Boring had seen a fluid extract, light in colour, which deposited until very little was left in solution.

Professor Maisch remarked that, in going over the reports, he had found no instance in which physicians had made experiments with cotton-root bark of the true origin of which they appeared to be aware.

A paper by Mr. F. B. Power, on elaterin, was read.

Dr. Miller wished to caution against the purchase of cheap sugar-coated quinia pills. He said there were in the market 45,000 such pills which do not contain a trace of quinia. They were made from muriate of cinchonia, furnished by a New York house as sulphate of quinia to some of the makers of sugar-coated pills, and by them thrown back on the hands of the dealer upon the discovery of the fraudulent nature of the article.

Mr. Blair called attention to the construction which the Internal Revenue officers place upon the law. They claim the right to go through premises from garret to cellar, whether they have reason to believe the law relating to the stamping of articles was being evaded or not. Those who are familiar with the construction and intention of the law, are of the opinion that it did not apply to the retail apothecary, but was intended for liquor and segar manufactories. The Government officers further claim, that a refusal on the part of the apothecary to permit such domiciliary examination makes him subject to a fine of 500 dols. Where there is reason to believe the law is being violated, and the officer is refused admission, it seems but proper that he should report to his superior, and procure a special warrant to examine the premises. Another understanding is that goods exposed for sale only must be stamped. The fact that these officers have, or assume, the right to make these visits, is subjecting apothecaries to an annoyance which is unjust, and a suggestion was made that they should use their influence, individually, with their representatives in Congress to have this law repealed or modified.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture II.

The Alcohol Group of Organic Bodies—Actions of different Alcohols.

(*Concluded from page* 594.)

Action of Methylic Alcohol.

Methylic alcohol, pyroxylic spirit or wood spirit, as it has been differently called, the spirit contained in the liquid got by distilling wood, has been known for about sixty-two years. It was discovered by Mr. Philip Taylor, in 1812, and was soon applied for lamps and for other purposes as a spirit. It was probably first made commercially by Messrs. Turnbull and Ramsay, of Glasgow. Its properties were investigated and reported upon by Sir Robert Kane, of Dublin, in 1836, and it was also analysed by Messrs. Dumas and Peligot, who determined that it contained 37·5 per cent. of carbon, 12·5 per cent. of hydrogen, and 50 per cent. of oxygen. When it is pure it remains clear in the atmosphere. It has an aromatic smell, with a slight acidity. The specimen I have used for my research had a specific weight of 810, water being 1000, and it boiled at 140° Fahr.

The spirit has been much used in the arts in the place of alcohol for making varnishes. Having a lower boiling point it is more volatile than common alcohol. It is now also largely used in museums for preserving purposes, and it yields on oxidation a very powerful preservative vinegar. For the sake of economy it is often employed in the manufacture of other compounds called methylated.

Owing to the volatile nature of this alcohol it may be exhibited freely by inhalation in the same manner that chloroform is administered. It then enters the blood by being carried with the air that is inspired into the pulmonary tract, and thus into the air vesicles. Here it is absorbed into the circulation by the minute blood-vessels which make their way from the heart over the lungs, and which ramify upon the vesicles. By administering the vapour of methylic alcohol in this way its effects are rapidly developed, for it condenses quickly in the blood, is carried rapidly into the left side of the heart, and thence is distributed by the arteries over the whole body as quickly as it is condensed and absorbed.

The alcohol may be administered in the same way, that is to say, in combination with water, hot or cold. In this way it is not unpleasant to the taste, and in one instance, as I am informed by a veteran member of my profession, this alcohol was invariably drunk by a well-known physician, in preference to common alcohol. He was accustomed to make it into toddy, with water and sugar, and considered that while it was as pleasant to take as ordinary spirituous drinks it was less injurious than they are. I have myself, of late years, when compelled to allow the administration of alcohol in some form, recommended this methylic lighter spirit, and, I am satisfied, with better results than if the heavier or ethylic spirit had been employed. I have ventured also to suggest that in many instances other physicians might follow the same practice with advantage; for methylic alcohol is much more rapid in its action, and much less prolonged in its effects than in common alcohol, so that it produces its effects promptly, and what is of most importance, it demands the least possible ultimate expenditure of animal force for its elimination from the body. This latter fact, I repeat, is of great moment, for, in the end, all these alcoholic fluids are depressants, and although at first, by their calling vigorously into play the natural forces, they seem to excite, and are therefore called stimulants, they themselves supply no force at any time, but cause expenditure of force, by which means they get away out of the body and therewith lead to exhaustion and paralysis of motion. In other words, the animal force which should be expended on the nutrition and sensation of the body, is in part expended on the alcohol, an entirely foreign expenditure.

The lighter the alcohol therefore, *cæteris paribus*, the less injurious its action, and so we may put down methylic alcohol as the safest of the series of bodies to which it belongs. But it is not without potency of effect, and the phenomena it produces are sufficiently demonstrative. Its effects are developed in four distinct stages.

The first stage is that of excitement of the nervous organisation; the pulse is quickened, the breathing is quickened, the surface of the body is flushed, and the pupil is dilated. After a little time there is sense of languor, the muscles falling into a state of prostration and the muscular movements becoming irregular. Thereupon the second stage follows, if the administration be continued. In this second stage the muscular prostration is increased, the breathing is laboured, and is attended by deep sighing movements at intervals of about four or five seconds, followed by further prostration, rolling over of the body upon the side, and distinct signs of intoxication. From this condition the subject passes into the third stage, which is that of entire intoxication, complete insensibility to pain, with unconsciousness of all external objects, and with inability to exert any voluntary muscular power. The breathing now becomes embarrassed and blowing, with what is technically called "bronchial rale," or rattle, due to the passage of air through fluid that has accumulated in the finer bronchial passages. The heart and lungs, however, even in this stage, retain their functions, and therefore recovery will take place if the conditions for it be favourable. Also, if the body be touched or irritated in parts, there will be response of motion, not from any knowledge or consciousness, but from what we physiologists call "reflex action;" that is to say, the impression we have made by irritation upon the surface of the body has travelled by its usual route through the nerves, to its nervous centre in the brain, and uncontrolled there by the consciousness has rolled back again, stimulating in its course some muscular fibre to motion. Probably the reason why the heart, which is a muscle, and the breathing muscles, continue to beat while all the other portions are at rest is due to this fact, that the blood which the heart drives to the brain and other nervous centres conveys to the centres which supply the heart a wave of motion that rolls back upon these vital muscles, and sustains them still in their rhythmical motion.

During all these stages there is no violent convulsive action from this alcohol, and no distinct tremor; but one phenomenon has been step by step more marked, and that phenomenon is a reduction of the animal temperature. Even though the body of the subject be exposed to a temperature of 84°, that is summer heat, it will begin to cool, from the first, and continually decline through all the stages, so that at last the loss of heat will become actually dangerous; for the body cannot throw off water freely, and therefore fluid collects in the lungs, and there is risk of what may be plainly considered suffocation like as from drowning. I have seen this decline of temperature from methylic alcohol, in animals narcotized by it, proceed to the loss of eight degrees of heat on Fahrenheit's scale when the insensibility was at its extreme point.

Presuming that the administration of the methylic spirit be continued when the third degree has been reached, there is a last stage, which is that of death. The two remaining nervous centres which feed the heart and respiration cease simultaneously to act, and all motion is over. After the death the blood throughout the body is found charged with the alcohol. The circulation of blood over the lungs has continued to the last, and so the lungs are found containing blood in both sides of the heart; the vessels of the brain are engorged with blood, as are the other vascular organs. The blood itself is not materially changed in physical quality, but

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

coagulates or form into clots, rather more slowly than usual.

If at the third stage of insensibility the administration of methylic spirit be stopped, recovery from the insensibility and prostration will invariably take place on one condition, that the body be kept dry and warm. From four to five hours, however, are necessary before the recovery is complete, and under the best conditions the restoration of the animal temperature is not perfect under a period of seven hours.

Happily we have no data to guide us that will show the effects on the animal body of the long-continued use of methylic alcohol, for men have not as yet steadily plied themselves with it as a drink to induce phenomena of chronic intoxication from it. The above-named facts, however, drawn from careful observations, in which the effects of the agent were seen on the inferior animals, and in one instance where the fluid was taken by accident by the human subject, show that methylic alcohol, though it may be less potent than its allies, is sufficiently potent, and the inference is fair, indeed, irresistible, that if the use of it were persevered in for long periods of time, it would lead to structural change in the body, just as all other chemical agents do that modify and pervert the natural mechanism. An agent that causes congestion of the brain cannot be employed many times without destroying the delicate organization of the vascular structure of the brain, neither can it influence the other vascular organs in the same way without prejudice to their structure; neither can it destroy the function of the nerves, of the muscles, and of the organs of the senses, without prejudice to their functions. In many respects this, the highest and least injurious of the alcohols, resembles chloroform in the ultimate action it produces on the body. It still more closely resembles ether, although recovery from the effects of both these agents is very much more rapid than from the spirit. It may consequently, as a chemical agent possessing a specific power of action over the living organism, be fairly classified with these agents. It is quite as artificial as they are, it is quite as dangerous in the long run, and its effects are more prolonged.

Action of Butylic Alcohol.

I pass over the second alcohol of our series, viz., ethylic alcohol, the common alcohol of wines and spirits, because that will of itself engage our attention for the remaining part of the course, after this lecture is concluded. I pass over propylic also for the reason that it is not easily separated as an alcohol, and is less perfectly studied than the other members of the group before us. Thus I am brought to what is called butylic alcohol.

With this spirit we arrive at one of the heavier bodies of the group in which, as our table shows, there is an increased proportion of carbon and hydrogen over those that are placed above it in the scale. Compared with common alcohol the weight of its vapour is as 37 to 23. Its weight, as a fluid, is 803 to 792, and its boiling point 230 Fahr. to 172. It is a heavier fluid; it mixes indifferently with water, but it is not unpleasant to take when diluted and sweetened. Applied to the lips and tongue when in a pure state it creates a sensation of burning, in the same way as common spirit, but with more intensity, and there is this remarkable fact connected with the sensation, that after the burning effect has passed away an extreme numbness of the part where the fluid was applied remains. I made this observation originally in 1869, and I have since often applied the knowledge with effect, in relieving, by the application of the agent, local pain. Toothache, for instance, is very quickly soothed by it.

The alcohol is not obtained by special process of distillation; it is produced with other alcohols in the process of fermentation, and is obtained by what is called fractional distillation, that is, by distillation of it at certain fixed temperatures, from fusil oil, or from the oil of beet-root, or from molasses after distillation of ethylic spirit.

The action of butylic alcohol on the animal body is divisible into four stages, the same as we have seen in respect to methylic spirit, but the period required for producing the different stages is greatly prolonged; and when the third stage, that of complete insensibility, is eached, there is added a new phenomenon which does not belong to any of the lighter alcohols. In this third degree, after the temperature of the body is depressed to the minimum by the butylic spirit, distinct tremors occur throughout the whole of the muscular system. These come on at regular intervals spontaneously, but they can be excited by a touch at any time, and in the intervals where they are absent there is frequent twitching of the muscles. The tremors themselves are not positively muscular contractions, but are rather vibrations or wave-like motions through the muscles, and are attended with an extreme deficiency of true contractile power in the muscular fibre. An electrical current passed through the muscles, which would, in health, throw them into rigid contraction, will now excite the tremors and keep them proceeding, but will not excite complete contraction. So long as the tremors are present the temperature of the body is depressed, falling even half a degree; but when they cease the temperature rises again, not to the natural standard, but to or near that which existed before the tremors were excited. After the tremors are once established, they continue without further administration of the alcohol for ten and twelve hours, and so slowly do they decline, they may remain in a slight degree even for thirty-six hours. They subside by remission of intensity and prolongation of interval of recurrence. One fact of singular significance attaches itself to these muscular tremors. They are the tremors which occur in man during the stage of alcoholic disease, when there is set up that malady to which we give the name of *delirium tremens*. An ordinary intoxication with a lighter alcohol is insufficient to produce this extreme perversion of nervous and muscular power, but the introduction of one of these heavier alcohols, or it may be the excessive saturation of the body with a lighter spirit, for on this point I am not sure, is sufficient to cause the tremulous motion. What the nature of the muscular movement is, what unnatural relationships exist between the nervous system, the muscles and the blood, to lead to them, are questions still unsolved. Involuntary, developed even against the will, excited by any external touch, attended with great reduction of temperature, and remaining as long as the temperature is reduced, they indicate an extreme depression of animal force; a condition in which all the force of life that remains has to be expended on the mere organic acts of life, on the support of the motions of the heart, the muscles of respiration, and the functions of the secreting glands. The voluntary systems of nerve and muscle are indeed well-nigh dead, and recovery rests entirely on the maintenance of the organic nervous power. Still recovery will take place if the body be sustained by external heat and by internal nourishment.

In the extreme stage of intoxication from butylic alcohol the red blood in the arteries loses its rich colour, and the blood, which flows with difficulty from the veins, is of a dirty hue. The blood coagulates readily, but the clot is loose, and the fibrine of which it is composed separates in a coarse network or mesh. The little corpuscles of the blood run into each other, forming rolls or columns. Indeed it is wonderful how the blood circulates through the structures it should nourish. The vascular membranes of the brain are found charged with this tarry blood; the brain structure is softened, and gives the odour of the poison, and the muscles, when divided by the knife, cut without firmness, yielding from numerous points the same tar-like blood. The vascular organs—spleen, liver, lungs, kidneys—are equally changed, and in a similar manner. Their fine structures are infiltrated with the deteriorated vascular fluid which was intended for their maintenance, and even the secretions and cavities of the body are perverted by being charged with fluid derived from the unnatural blood. This is the state of the body of one who dies insensible after the delirium and tremors which mark even the human malady, self-inflicted and terrible, known as *delirium tremens.*

Action of Amylic Alcohol.

Amylic alcohol, the next of our series, is obtained by the fermentation of potato starch, or starch of grain, and when pure is a colourless fluid. Its weight compared with water as 1,000 is 818, and it boils at 270° Fahr. It is from this alcohol that the active substance, nitrate of amyl, to which I have before referred, is derived. The odour of amylic alcohol is sweet, nauseous, and heavy. The sensation of its presence remains long. In taste it is burning and acrid, and it is itself practically insoluble in water. When it is diluted with common alcohol it dissolves freely in water, and gives a soft and rather unctuous flavour, I may call it a fruity flavour, something like that of ripe pears. From the quantities of it imported into this country it is believed to be employed largely in the adulteration of wines and spirits.

Amylic alcohol, when it is introduced as an adulterant, is an extremely dangerous addition to ordinary alcohol, in whatever form it is presented, whether as wine or spirit. Its action on the body is the same as that of butylic alcohol. It produces three stages of insensibility, ending in the profoundest narcotism, or coma, followed by reduction of temperature and by muscular tremors. These tremors recur with the most perfect regularity of themselves, but they can be excited at any moment by touching the body, or blowing upon it, or even by a sharp noise, such as the snap of the finger. In all other respects the phenomena induced are the same as are observed from butylic alcohol, except that they are much more prolonged, from two to three days being sometimes required for the complete restoration of the animal temperature. The reason of this prolongation of action lies in the greater weight and the greater insolubility of this spirit, that is to say, the force required to decompose it, or mechanically to lift it out of the body when it has once entered it, is so much greater than is required for the lighter spirits, which can diffuse readily through the secretions, volatilise by the breath and possibly undergo rapid decomposition. The odour of the substance remains for many hours in the animal tissues. Amylic alcohol acts upon some resins and resinous substances, I believe, dissolving certain of them more easily than the lighter spirits, but its peculiar odour prevents its application on a large scale.

Action of Sodium and Potassium Alcohols.

The action of the sodium and potassium alcohols is exceedingly interesting in a physiological point of view, and in this I think only, except in respect to their varied uses as chemical re-agents. They act on the living animal tissues as caustics, and will one day be considered of great service to the surgeon. Brought into contact with blood in solution, there is produced by them an almost instant crystallization of needle-like crystals spread out in beautiful arborescent filaments. This arborescent appearance is identical with a crystallization which can be induced in the alcohols themselves, but there are also formed smaller radiant crystals due to the crystallization of the crystalloidal matter of the blood cells, and singularly like the forms which, since the time of Dr. Richard Mead, have been described as occurring in the blood after infection by the poison of the viper.

These metallic alcohols are powerful antiseptics, like common alcohol, over which they have an advantage in that they more thoroughly harden soft structures. I have taken advantage of this action to employ them for the preservation of nervous matter, which is rapidly prone to decomposition.

I should add that, by some chemists these alcohols are called ethylates of sodium or potassium, a term which is thought to define more correctly their chemical construction.

Action of Mercaptan or Sulphur Alcohol.

I have already referred briefly to this most curious body of the alcohol series, describing it as an alcohol in which oxygen is replaced by sulphur. In experimenting with it a solution containing 5 per cent. is sufficient, and the vapour of it may be inhaled in order to produce its effects. These are most remarkable.

I found, by direct experiment, that the vapour is not irritating to breathe, but that its influence on the system is speedily pronounced. There is a desire for sleep, and a strange, unhappy sensation, as if some actual or impending trouble were at hand. This is succeeded by an easy but extreme sensation of muscular fatigue ; the limbs feel too heavy to be lifted, and rest is absolutely necessary. There is, at the same time, no insensibility to pain, and no intoxication. The pulse is rendered feeble and slow, and remains so for one or two hours, but, in time, all the effects pass off, and active motion in the air helps quickly to dispose of them.

On the inferior animals the action of mercaptan is equally peculiar. Frogs exposed to its vapour fall asleep, and seem to pass into actual death, except that the eye remains bright. They may be left in this apparently lifeless state for half an hour, then, removed into the air, in the course of an hour and a half or two hours they commence to breathe again, and gradually recover, precisely as if they were awakening from sleep. The action of this alcohol on the animal body, though it produces these extreme effects, is less injurious than that of the other alcohols. It escapes mainly by the breath, and in some new form, as a sulphur compound. It thus communicates to the breath an odour which is by no means uncommon in persons who indulge to a great extent in the use of ordinary alcohol. This observation suggests a most important explanation of certain phenomena connected with the action of common alcohol. It appears to me that in some states there is actually produced in the living organism, by the vital chemistry, sulphur compounds, derived probably from the bile, a substance rich in sulphur, which compounds, distributed by the blood to the nervous matter, create the phenomena similar to those I have described as following upon the inhalation of mercaptan. Thus, under unnatural modes of life, the body actually makes its own poisons, and the doctor is often asked to remove what the patient, if he were a better chemist and a wiser man, would never produce for the exercise of the doctor's skill.

Parliamentary and Law Proceedings.

Irregular Medical Practice.

An inquest was commenced on the 11th instant, at Redruth, respecting the death of James Carkeek. From the evidence, it appeared that the deceased having fallen and hurt his elbow was attended by his club doctor, Mr. Hitchen. The deceased or his wife being dissatisfied with Mr. Hitchen's treatment, Dr. Rowe, a registered chemist and druggist, was called in. Of this fact Mr. Hitchen was not informed until he noticed that his instructions were not being followed. He then refused to attend any longer. Dr. Rowe continued to attend, and the deceased was afterwards visited by Dr. Hudson, but eventually died on the 8th inst. The jury returned a verdict of "Accidental Death," adding their opinion that Mr. Hitchen was perfectly justified in withdrawing from the case when he found his directions were not followed out.

Charge of Poisoning.

A domestic servant named Matilda Alberta Foreman is in custody at Diss, Norfolk, on a charge of attempting to poison an infant named Robert Balls, by administering to it tea with which arsenic had been mixed. The accusation against the prisoner is that she was instructed by her mistress, Mrs. Balls, to make some tea, and that she put into the teapot some arsenic which was lying in a cupboard for the purpose of destroying rats, and which she had been cautioned not to touch. The child drank some of the tea which the prisoner had made, and almost immediately became very ill, and vomited into his mother's lap. The prisoner was immediately accused by Mrs. Balls of having put arsenic into the tea, and she admitted having done so, being unable, at the same time, to give any reason or explanation for her conduct. The contents of the teapot were poured by Mrs. Balls into a basin, and the girl threw the poisoned tea away when her mistress's back was turned. When Mr. Balls returned home he destroyed the remainder of the poison. The child eventually recovered.—*Daily News.*

Review.

Report by Dr. M. C. Cooke, on the Gums, Gum-resins, Oleo-resins, and Resinous Products in the India Museum, or produced in India. Prepared under the Direction of the Reporter on the Products of India. London: India Museum. 1874.

Any fresh information concerning the natural products of India, more particularly those of a medicinal or economical character, cannot fail to be interesting. Few countries produce such a varied assortment of gums and gum resins, yet comparatively little is known concerning the origin of many of them, and the little that is known is surrounded with more or less of uncertainty. The difficulties in the way of obtaining reliable information from the natives who collect these products, is very great, every inquiry relative to these natural productions being met by the natives with replies intended to throw the inquirer off the scent, and to prevent his causing injury to their trade. Added to this, the difference in the native names and districts is very wide, as will be seen by reference to the list of native names in this report. A further difficulty arises from the fact that many of these substances are not produced in, but imported into India from other countries. For these reasons neither a botanical nor an alphabetical arrangement of these products is possible.

Hence the only convenient one has been followed, and the products treated of and arranged under four heads, viz.:—Gums, Gum-resins, Resins, and Oleo-resins.

These, again, are divided into lesser groups, according to the necessities of the case; thus Gums are arranged under True Gums, Bassorin or Pseudo-Gums, and Astringent Gums. Each article is placed under the botanical name of the plant supposed to yield it, or where that cannot be ascertained, the name of the article is substituted, and these names are arranged alphabetically, references to plates, a list of botanical synonyms, and of the native names in different dialects, a short botanical description, and in the better known articles, such as myrrh, gamboge, etc., an account of the bibliography, and tables of the exports from and imports into the Bombay Presidency alone, are given, while copious extracts from various works are quoted.

By this means the different and often contradictory accounts of the sources of the products are thus laid before the reader at one glance; but the large space so occupied might perhaps have been more advantageously used for practical information upon the properties and possible uses of many of the articles, original information of this kind concerning a large number of them being exceedingly scanty. This is acknowledged in a prefatory note by Dr. Watson, who states that a very extended series of experiments is necessary to determine their commercial value and possible uses, and to this end gives a few practical hints to those who send home specimens to be reported upon, and these hints it may be useful to briefly quote here.

"1. In most cases 20 or 25 pounds are sufficient for the purpose; but it is comparatively useless to send quantities so small that when diminished by five or six samples to brokers and traders sufficient is not left for analysis or experiment.

"2. Samples should be sorted into different qualities, as this can be done more economically in India, and would find its return in the prices obtained.

"3. The botanical source should be accurately indicated, and specimens of leaves, flowers, and, when possible, fruits of the plants yielding them should accompany each sample.

"4. A first unfavourable report should not be taken as decisive, as subsequent trials and experiments might show a before unthought-of use."

A few curious facts appear from the tables of imports and exports.

Thus, with regard to gum Arabic in 1871-2, 120 tons were exported to Japan, or twice as much as to America during the same year, although during the two years previously none had been exported to the former country. Bissabôl, commonly known as East Indian myrrh, and which is imported chiefly from Aden, appears to be exported to China alone.

Gum Bdellium, which is also produced in Scinde, is imported from the Red Sea. It is not stated whether this be African or Indian Bdellium, although the botanical source is given as *Balsamodendron Mukul*, Hook. One of the uses to which it is put is to mix the decoction with plaster in building so as to give it durability.

Benzoin and Olibanum do not appear to be exported to any extent direct to Italy or Spain, and very little to France, although they must be used as incense to some extent in these countries.

Amongst the gums of the gum arabic class the more remarkable appear to be those of *Buchanania latifolia*, Roxb., or Chironji gum, which is said to be more adhesive than gum arabic, but otherwise resembling Bassorah gum; the Dhowra gum (*Conocarpus latifolius*, Roxb.), which is used in "cloth printing," and could be obtained in large quantities at a low price, but which is only partly soluble; Jumrasi gum (*Elæodendron paniculatum*, W. and A.), which yields a tenacious mucilage of a sherry colour; that of *Feronia elephantum*, Corr., said to form a portion of East Indian gum Arabic, and which is stated to be the best gum for using in the manufacture of ink, as it readily dissolves and leaves no residue; that of the mahogany tree (*Swietenia Mahogani*, L.), a beautiful silvery gum of superior quality, produced in great abundance; and a kind resembling Senegal gum, yielded in large quantity by one of the Myrabolans trees (*Terminalia belerica*, Roxb.). The gum of *Swietenia chloroxylon* (Roxb.) is said to have this remarkable peculiarity, that it becomes covered in an hour or two with a thick pellicle, the upper part of which becomes quite dry, and which when broken rapidly forms again. Among the Bassorin gums may be noticed that of *Cycas circinalis*, L., used to promote rapid suppuration in malignant ulcers; of *Macaranga tomentosa*, W., of a light crimson colour, used for taking impressions of leaves, coins, medallions, etc. When the gum is pure the impression is said to be as sharp as that of sulphur, while it is without its brittleness. Of the astringent gums may be noticed that of *Pterocarpus indicus*, Willd.; it has a somewhat disagreeable odour, but might be used in making ink.

The exudation of *Garcinia cambogia* is said to form, when dissolved in turpentine, a very beautiful yellow varnish for metal, etc., although it will not form an emulsion like true Camboge.

The resin of *Terminalia angustifolia*, W. and A., is of an agreeable scent, between benzoin and olibanum, and contains benzoic acid; it is used as incense or in powder as a cosmetic.

Among the resins the notice of piney resin gives some interesting particulars. It differs from copal in being soluble at once in turpentine and drying oils. The turpentine solution is turbid and milky, but by the addition of powdered charcoal and subsequent filtering, it yields a varnish which dries with a purity and whiteness not to be surpassed. Candles are made of it, which in burning diffuse an agreeable fragrance, and give a clear light with little smoke; they consume the wick without snuffing.

One curious substance called Pwai-ngyet, and which is usually considered to be a kind of black dammer, appears to be the nest of a kind of bee (*Trigona læviceps*). The insect collects different resins, and oleo-resins, such as wood oil, and makes its nest in hollows of trees, of cells which lack the geometric regularity of those of the honey bee. The nest has a remarkable entrance protruding from the tree of the shape of a trumpet flattened, the mouth being a foot long by three or four inches across; of this curious structure an illustration is given.

Canarium Bengalense, Roxb., is said to yield in quantity a very pure, clear amber-coloured resin, like copal, which fetches but a low price in the Calcutta bazaars.

Of natural varnishes that of *Melanorrhœa usitatissima*, Wall, is used by the Burmese as a lacquer, for gilding, as a writing fluid, and internally as an anthelmintic. It is soluble in alcohol, turpentine, and benzole. The pericarp of the marking nut, *Semecarpus Anacardium*, L., yields a resinous juice, said by Dr. Bridwood to be the black varnish of Sylhet. It is this which has lately been recommended as a marking ink. Either of these native varnishes properly diluted would probably make excellent ink for documents in which the permanence of colour is an object.

Some excellent turpentine is produced by *Pinus Khasyana*, Brandis, and *P. Massoniana*, Lieb. and Zucc., but their present prices can by no means compete with those in European commerce. An appendix to the report contains Dr. Birdwood's paper on the genus *Boswellia*, published in the Linnean Transactions in 1869, together with four plates of *B. Carterii*, *B. Frereana*, and *B. Bhaudajiana*.

The Graduation of Glass Measures.

Sir,—Allow me to draw the attention of your readers to a small matter, which, however, as it stands at present, is a source of inconvenience, and even of danger to life.

In common with many others it is my habit in prescribing mixtures containing active remedies, to direct that the medicine be taken out of a glass measure. But in two instances which have recently occurred to me each of the patients swallowed three tablespoonfuls instead of one, as directed. The cause of this I found to be the mode in which many of the graduated glass measures sold by pharmaceutists are inscribed. The word tablespoon is placed on the glass opposite to the line intended to indicate three tablespoonfuls. In one of the cases spoken of the medicine given to the patient consisted of chloral hydrate, and as the three tablespoonfuls were repeated after a short interval, somewhat alarming results followed. In the other case the medicine contained strychnia, and the mistake was discovered by the unexpected development of its constitutional effects.

All this it may be said was due to stupidity in not recognizing that each mark on the glass indicated a tablespoonful. But we must take people as we find them, and unless a change is made in the glasses spoken of it will be far better to trust to the actual tablespoon, variable as it is, than to the measures used when accuracy of the dose is vainly supposed to be insured.

Arthur Leared, M.D.

The Drug Trade and Late Hours.

Sir,—The glowing descriptions we have lately seen of the trade and its prospects induce me to trouble you with a little of my experience. The late work after shop hours is a serious drawback to the business and might be reduced very much without inconveniencing the public. I find on an average that three-fourths of the calls after shop is closed are for articles that might have been purchased during the day, such as Epsom salts, castor oil, pills, seidlitz powders, etc.

In such cases I remind the customers of the late hour and suggest their taking several doses, to save them the trouble of coming again at this time of night, and this plan has already brought some of the old and regular offenders into better habits.

If chemists in large towns would combine together and not serve anything after shop hours except new prescriptions, that would lessen the hours of labour very much for many assistants. Why should Mr. or Mrs. So-and-so make a regular habit of waiting until the servant comes to post, or is dressed for the evening, to send to the chemist's for the usual mixture, or pills, or night draught. Sometimes I find new prescriptions, written about 11 a.m., are kept at the house until 8 or 9 p.m. and then sent down to be made up, with a message to be sent directly.

When this happens I generally ask the messenger to wait or call again, as my porter has gone for the night and I have not anyone to send. Many of us are veritable slaves to our businesses, and it behoves us, as a matter of health and duty to ourselves, to make a protest against such excessive and unjust demands on our time and attention.

A clergyman, doctor, and chemist, are popularly supposed to be always at hand, and ready to render assistance in case of need.

The two first-mentioned receive that consideration and respect to which they are justly entitled by their position in society; but the chemist is only looked upon as a tradesman, and has the duties and responsibilities of a professional man, without either his position or any adequate remuneration.

I look upon the present time as a very trying period for principals and assistants, and think both are feeling the effects of "The Pharmacy Act" rather acutely just now, but hope the state of affairs will improve, and that we shall all be able to employ examined assistants at more remunerative salaries. At present the returns of many businesses are so small that keeping an assistant is out of the question, and taking everything into consideration, one cannot help recognizing the fact that the education required is too expensive for the business, if looked at in a commercial point of view. I do not wish to see our business made too exclusive or purely dispensing; what I maintain is that for such responsible and skilled labour as the preparation of medicines the public ought to pay a fair, reasonable price, and they should not expect powerful remedies dispensed at the same rate of profit as sundries sold retail.

The labourer is worthy of his hire, and to us time is money; a fact which, unfortunately, many of our customers do not seem to be aware of.

Frater.

Sir,—I am afraid that "Veritas," if he has not yet arrived at the age of forty, has been labouring under the great disadvantage of looking through a glass darkly, and at some time will have to awaken to stern reality. If, however, I am wrong in my surmises, and "Veritas" has passed the "shady side of forty," surely with such a nice little income as he must be possessed of, 'tis making "much ado about nothing." "Veritas" says: "A young man with £200 or £300 to commence with may confidently hope to retire on £500 per year by the time he is forty, and on £1,000 a year by the time he is fifty, and he is not nearly so likely to do that in either the hat, drapery, tea, or ironmongery trade; but there is one qualification necessary to accomplish this, he must be a man of business." Now, Sir, I ask did any one ever hear of such a Utopian idea? Can "Veritas" really mean what he writes, and does he hold it out as a stimulus to the 64 unsuccessful candidates who have presented themselves for examination since October to December last, or is it a sketch of imagination, or has he himself proved by practical illustration that such is the case? If the latter, I strongly recommend the Secretary of the Pharmaceutical Society to write him for a magnificent donation to the Benevolent Fund; but if the former, I am sadly afraid that those who are looking forward to the good times when they shall have reached the age of forty, and hoping to retire into private life, taking Shakespeare's advice, and "throwing physic to the dogs," will have found the old saying true, "that hope deferred maketh the heart sick."

Now, let us in the first place look at the case from a business point of view. If a person invested money at 5 per cent. per annum, to bring in an interest of £500 per year, he would have to invest £10,000, and if to bring in an interest of £1,000 per year, of course £20,000 would have to be invested. Now, will "Veritas" look through the advertising columns of the various trade journals and see what kind of a business can be bought for £300? Generally one with a return of about £400 yearly. But suppose a young man were especially fortunate, and happened to meet with one returning £600 per year, and that he takes it when he is twenty-three years old, and having very excellent business capacities, he manages the first five years to average £800 per year returns, and the next five years £1,000 per year, and the last seven years £1,200 per year (this, of course, would be a rather unusual case, but for the sake of making out a case, we will look at the bright side of the picture). He will then have arrived at the age of forty, and will have taken money to the amount of £17,400. This, of course, would average £1,024 per year. Well, what reasonable profit might we suppose to be made on that, say £500 (which I very much doubt in these days of mutual supply associations, co-operative stores, and Civil Service stores, could be made on that return), and out of that there is rent, rates, taxes, bad debts, education of children, and placing them to various trades, perhaps sickness, for none of us are proof against that; relief to oppressed brethren, the salary of assistants, the wages of servants, and many other expenses would, I think, leave little margin to save anything at all. How, then, is the £10,000 to be made in the seventeen years? Something might possibly be saved the first few years, but if the said young man thinks, with Scripture, that it is not well for man to live alone, he will soon find that his expenses increase and multiply. But "Veritas" says, work for ten years more, and you will be able to save what will bring in £1,000 yearly. Whatever "Veritas" thinks, my candid opinion is, that if his picture were a true one, we should not hear quite so much taunting about "ekeing out a miserable existence," the large number of applicants for the Benevolent Fund, the cry of the assistants that the prize is not worth the struggle, and the reason why chemists' assistants are not better remunerated, because the employers cannot afford to pay higher salaries. As to the idea of making less in either the tea, drapery, or ironmongery trade, the thought is not worth the paper it is written on, for though chemists as a rule hold as high a standard of respectability as any tradesmen, I think, that looking in a financial point, they are about the worst remunerated of any.

Look through the advertisements, and you will find it a perfect El Dorado where the returns are £1,000 yearly; but to reach £1,500 is the seventh heaven of bliss. Why, sir, 'tis making the trade into a perfect gold mine, and to hear of persons retiring on £1,000 per year when they have arrived at the age of fifty; if it were true I fancy that instead of being short of assistants we should be overstocked, and everybody would be working might and main to pass the Examinations, and get into business.

In conclusion, I do not wish to have said anything to hurt the feelings of "Veritas," but I trust with a careful examination of the subject, he will let such ideas pass for ever from his mind, like the "baseless fabric of a dream."

AMOR VERITATIS.

Sir,—Allow me, through the medium of your columns, to congratulate my fellow assistants upon the El Dorado into which we have entered unawares.

From the letter of "Veritas" in your last I hear for the first time the following satisfactory fact, that a business-like young man with about £300 may hope to retire from the drug trade at the age of 50 with an income of £1,000 a year. Of course "Veritas" is aware that to retire with £1,000 a year requires about £20,000 to have been saved, and assuming a young man to set up in business when 25, there must be an average annual saving of £800. Add to this £300 for expenses of living, and we have nett profits £1,100, which means returns of about £4,000.

Surely there must be an average number of business-like young men who enter the drug trade, but if a return could be obtained of the returns of drug businesses in Great Britain, would the result bear out the foregoing figures?

E. NUTHALL.

Bank Plain, Norwich.
January 19, 1875.

Errata.—The Genus Pilocarpus.—Page 583, col. i., line 21, *for* "originally defined by Vahl," *read* "defined by De Candolle." In foot-note to same column, *for* "Vahl, Eclog. i., p. 20," *read* "De Candolle, Prodromus, vol. i., pp. 7, 8."

A. D.—Straining is the only mode of making such an incompatible mixture present an elegant appearance, but that would not be justifiable. The prescriber ought to have been communicated with, if possible, before it was dispensed in the first instance.

E. J. C.—We know of nothing to prevent the widow of a chemist and druggist from taking an apprentice; but whether she would be able to fulfil the terms of the indenture would depend upon the nature of those terms.

J. E. Doo.—Your communication has been handed to the Secretary.

A. C. W.—The *Lotio Calcii Sulphurati* of the University College Hospital Pharmacopœia.

"Slaked Lime . . . . 4 ounces.
Sublimed Sulphur . . . . 4 ,,
Distilled Water . . . . . 35 ,,

Boil together, evaporate and filter to produce one pint of the solution."

"*A Puzzled Dispenser.*"—*Ung. Acidi Boracici Co.* (Gibbon or Rick). We are not acquainted with either of these formulæ, but think it probable that some such preparation as Professor Lister's Boracic Acid Ointment, described before, p. 439, is intended.

J. Wood.—About thirty.

W. Dale.—We think the sale would still be subject to the regulations pertaining to the sale of fireworks.

X. Y. Z. is referred to the regulations respecting anonymous communications.

J. Gerrard.—Try the formula given on p. 579.

H. B. Atkinson (Sheffield).—The report published was in all essential particulars consistent with the one sent by yourself. We do not agree with you in considering the latter a more detailed account, or that it would have given the public any further explanation than the report we published.

"*A Grower.*"—We know of no work which is specially devoted to the subject you mention.

"*A Student.*"—(1) It would be about 55 over proof. (2) A Table is given in Griffin's 'Chemical Testing of Wines and Spirits,' published by Griffin and Co., Long Acre.

Mr. J. Taylor.—We are obliged for the letter you have forwarded. It appears to contain only ignorant abuse that deserves no notice.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Pocklington, Messrs. Low and Co., Mr. J. C. Hunter Mr. Munro, "Veritas," "Spes."

ON THE CONSTRUCTION OF AN INTERNATIONAL PHARMACOPŒIA.*

BY FRANCIS SUTTON, F.C.S.

The purpose of this paper is not in the first instance to attempt any strict definition of the principles upon which an International Pharmacopœia should be constructed, but to open the question for discussion among English pharmaceutical chemists, to whom the matter has been hitherto somewhat of a novelty.

However the idea of a Universal Pharmacopœia may have originated in the first instance, it seems to have assumed a definite shape during the second meeting of the International Pharmaceutical Congress at Paris in 1867, and there and then the Pharmaceutical Society of Paris was formally commissioned to arrange such a work in manuscript, and submit it as a basis of operation to the next meeting of the Congress at Vienna in 1869. It was not, however, ready at that time owing to the considerable amount of labour and time required on such a work, then the sad Franco-German war still further delayed both that and the meeting of the Congress, so that five years passed away and brought the Congress of St. Petersburg in August last year. At that meeting the finished manuscript copy of the proposed work was presented to the Congress, together with a Preface written by M. Boudet, President of the French Commission, explaining the rules and principles by which they had been guided in the construction of the work. It would be too long to insert the whole of this Preface here, but important parts of it will be given further on.

The French Commission was composed of thirteen members, and included the names of the highest authorities in chemistry and pharmacy to be found in the Empire.

It would only seem right, whatever our opinions may be about either the necessity of or the mode of construction of such a Pharmacopœia, to acknowledge with thankfulness the labours of these gentlemen, and to assume that theirs has been no light task, but one which has required delicacy, tact, and judgment in their attempt to satisfy the claims of other nations than their own.

There being only one copy in existence at present of the proposed Pharmacopœia it is of course impossible to criticize it in detail, but as one of your representatives at the last meeting of the Congress, I had the opportunity in a slight degree of inspecting the work, and I now propose to give a short history of its contents.

The Codex of 1866 is tolerably well known to some of us, and it may perhaps hardly be necessary to say that the outline and general features of the new work are the same; but there are also great differences.

The Codex is a book of 830 printed pages, royal octavo size, while the proposed work consists only of 534 pages of manuscript, post quarto, many of which are not half filled.

The printed book would therefore be less than half the size of the Codex of 1866, and as will be seen from the list of contents, is shorn of many preparations of a trivial and local character contained in the Codex, such as syrups, electuaries, tisanes, broths, wines, beers, vinegars, etc.

It is evident that the Commission have largely consulted the British and American Pharmacopœias in the construction of the book, and have been guided by an earnest desire to make it as cosmopolitan in character as possible. Nevertheless, it would be unreasonable to expect the work to be entirely free from national tinges.

When this manuscript was presented to the St. Petersburg Congress, a special committee of the delegates was appointed, and a certain portion of the work allotted to each delegate according to his choice, upon which, with the assistance of pharmacists of his own nation, he might proceed to alter, amend or add to, as in their judgment might seem fit. The corrected work was to be returned to a standing committee in St. Petersburg in December 1874; there to be translated into Latin, and rough proofs printed or lithographed for distribution to the various governments and Societies represented at the Congress.

Before proceeding to any discussion on the merits of the compilation, it will be well to give the summary of contents:—

PART I.—PRELIMINARY MATTERS.

Tables of weights, measures, specific gravities, temperatures, alcoholic strengths, etc.

PART II.—MATERIA MEDICA.

Pharmacognostic history and description of natural products.

PART III.—THE PHARMACOPŒIA,

COMPRISING THE FOLLOWING PREPARATIONS.

(It will be noticed that these are placed alphabetically, according to the system of nomenclature adopted in the French Codex.)

Acetate of morphia.
Acetate of potassium.
Acetate of sodium.
Acid, acetic, glacial.
Acid, acetic, dilute.
Acid, arsenious.
Acid, benzoic, sublimed.
Acid, boracic, crystals.
Acid, hydrochloric, liquid.
Acid, chromic, crystals.
Acid, chromic, liquid.
Acid, citric.
Acid, hydrocyanic, medicinal.
Acid, nitric, fuming.
Acid, nitric, officinal.
Acid, phenic.
Acid, phosphoric, dilute.
Acid, sulphuric, alcoholized.
Acid, sulphuric, dilute.
Acid, sulphuric, pure.
Acid, tannic.
Acid, tartaric.
Acid, valerianic.
Aconitine.
Alcohol.
Alcohol, camphorated.
Alcoholic tinctures.
Ammonia, liquid.
Antimony, purified metal.
Silver, pure metal.
Arseniate of sodium, crystals.
Atropine.
Lard.
Lard, benzoated.
Benzoate of sodium.
Borate of sodium.
Balsam of opodeldoc.
Butter of cacao.
Butter of mace.
Bromine.
Bromide of potassium.
Cadmium.
Carbonate of ammonium.
Carbonate of calcium, precipitated.
Carbonate of magnesium.
Carbonate of lead.
Carbonate of potassium.
Carbonate, bi-, of potassium.
Carbonate of sodium.
Carbonate, bi-, of sodium.
Caustic, fused (potassa cum calce).
Charcoal, vegetable.
Calcium oxide.
Calcium oxide, hydrated.
Calcium oxide, hypochlorite.
Chloramide of mercury.
Chlorate of potassium.
Chlorhydrate of ammonium.
Chlorhydrate of morphia.
Chloroform.
Chloride of antimony, proto.
Chloride of barium.
Chloride of calcium.
Chloride of iron, per-.
Chloride of mercury, per-.
Chloride of mercury, per-, solution.
Chloride of mercury, proto-.
Chloride of gold.
Chloride of gold and sodium.
Chloride of zinc.
Citrate of magnesia.
Citrate of magnesia, effervescent.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, on Wednesday, February 3, 1875.

Codeine.
Collodion.
Collodion of cantharides.
Collodion, elastic.
Cyanide of potassium.
Decoction, Sydenham's.
Dextrine.
Digitaline crystals.
Lime water.
Phagadenic water.
Seidlitz water, artificial.
Camphorated eau de vie.
Cinnamon water, distilled.
Orange-flower water, distilled.
Cherry laurel water, distilled.
Magnesia water.
Sponges, prepared.
Plaster of acetate of copper.
Plaster of assafœtida.
Plaster of cantharides.
Plaster of cantharides, perpetual.
Plaster of hemlock.
Plaster of extract of hemlock.
Plaster of extract of digitalis
Plaster of extract of stramonium.
Plaster of extract of opium.
Plaster of dyachylon.
Plaster of mercury.
Plaster of oxide of iron.
Plaster of lead, brown.
Plaster of burgundy pitch.
Plaster of soap.
Plaster of soap, camphorated.
Plaster, simple.
Plaster of antimony (by incorporation).
Plaster of mullein.
Plaster, English blistering.
Plaster, blistering (mouches au Milan).
Species laxative of St. Germain.
Ether, acetic.
Ether, sulphuric.
Ether, sulphuric with alcohol.
Extract of aconite.
Extract of aconite, alcoholic.
Extract of aloes, aqueous.
Extract of belladonna, alcoholic.
Extract of belladonna, aqueous.
Extract of calabar bean.
Extract of colocynth, compound.
Extract of stramonium, alcoholic.
Extract of ipecacuanha, alcoholic.
Extract of digitalis, alcoholic.
Extract of henbane, alcoholic.
Extract of nux vomica, alcoholic.
Extract of opium.
Extract of cinchona.
Extract of cinchona, yellow, liquid.
Extract of cinchona calisaya, alcoholic.
Extract of rhatany.
Extract of rhubarb.
Extract of valerian.
Extract of male fern, ethereal.
Extract of euphorbium, ethereal.
Extracts, fluid.
Iron reduced by hydrogen.
Pyroxylin.
Gargle, astringent.
Glycerate of starch.
Glycerate of extract of belladonna.
Glycerate of tar.
Glycerate of iodide of potassium.
Glycerate of sulphur.
Glycerate of tannin.
Granules of arsenious acid.
Oil of belladonna.
Oil of hemlock.
Oil of henbane.
Oil, camphorated.
Oil of croton tiglium.
Oil, phosphorized.
Hypochlorite of lime solution.
Hypochlorite of soda solution.
Iodine.
Iodide of iron, proto-, normal solution.
Iodide of mercury, proto-
Iodide of mercury, per-.
Iodide of lead.
Iodide of potassium.
Kermes, mineral.
Lactate of iron.
Filings of iron.

Liniment of lime.
Lohoch, white.
Lotion of ammonia, camphorated.
Magnesium oxide, calcined.
Honey, simple.
Mellate of mercury.
Mellate of red rose.
Mercury.
Morphia.
Mucilage of gum tragacanth.
Nitrate of silver, crystals.
Nitrate of silver, fused.
Nitrate of bismuth, sub-.
Nitrate of mercury, acid per-.
Nitrate of potash.
Ointment of ammonia.
Ointment, antipsoric.
Ointment, basilicon.
Ointment of belladonna.
Ointment of digitalis.
Ointment of henbane.
Ointment of hemlock.
Ointment of stramonium.
Ointment of camphor.
Ointment of cevadilla.
Ointment of chloroform.
Ointment of calomel.
Ointment of mercury (white precipitate).
Ointment of wax.
Ointment of wax, compound.
Ointment of wax, opiated.
Ointment of wax with lead.
Ointment, citrine.
Ointment, epispastic (green).
Ointment, epispastic (by incorporation).
Ointment, epispastic (euphorbium).
Ointment of tar.
Ointment of potassium iodide.
Ointment, mercurial, of equal parts.
Ointment of mace, compound
Ointment of mercury, red oxide.
Ointment of poplar.
Ointment, simple.
Ointment of sulphur.
Ointment of spermaceti (cold cream).
Ointment of antimony.
Ointment of styrax.
Ointment of turpentine.
Gold, metallic.
Oxalate of potassium, bi-.
Oxide of antimony.
Oxide of manganese.
Oxide of mercury, red.
Oxide of lead, fused.
Oxide of iron, red anhydrous.
Oxide of iron, red hydrated.
Oxide of zinc.
Oxymel, simple.
Oxymel of squills.
Paper plasters.
Permanganate of potassium.
Phosphate of calcium, tribasic.
Phosphate of sodium.
Phosphorus.
Pill of aloes.
Pill of aloes and gamboge.
Pill of colocynth, compound.
Pill of protocarbonate of iron.
Pill of protoiodide of iron.
Pill of henbane and valerian.
Pill of mercury, simple.
Pill of rhubarb, compound.
Lead, metallic.
Potassium hydrate, caustic.
Potion, effervescing.
Potion, laxative.
Potion purgative of citrate of magnesia.
Powder of belladonna leaves
Powder of hartshorn.
Powder, gazogene, alkaline.
Powder, gazogene, laxative.
Powder of protoiodide of iron.
Powder of ipecacuanha.
Powder of ipecacuanha, opiated.
Powder of linseed.
Powder of black mustard.
Powder of opium.
Pyrophosphate of iron, citro-ammoniacal.
Pyrophosphate of sodium.
Quinine.
Resin of jalap.
Resin of scammony.
Resin of mullein.
Santonine.
Soap, medicinal.
Soap, beef marrow.
Syrup of morphia hydrochlorate.
Syrup of codeia.
Syrup of extract of opium.
Syrup of iodide of iron.
Syrup of ipecacuanha.
Syrup of cinchona bark.
Syrup of cinchona bark, vinous.
Sodium hydrate, liquid.
Sulphur, flowers of, washed.
Sulphur, precipitated.
Strychnia.
Amber.
Cane sugar.
Milk sugar.
Sulphate of aluminium and potassium.
Sulphate of atropine, neutral.
Sulphate of cadmium.
Sulphate of copper.
Sulphate of iron crystals.
Sulphate of magnesium.
Sulphate of morphia.
Sulphate of quinine.
Sulphate of sodium.
Sulphate of strychnia.
Sulphate of zinc.
Sulphide of antimony.
Sulphide of potassium, impure.
Sulphide of sodium.
Sulphide of antimony, golden.
Tablets, or lozenges, of ipecacuanha.
Tablets, or lozenges, of kermes mineral.
Tablets, or lozenges, of peppermint.
Tablets, or lozenges, of bicarbonate of sodium.
Tablets, or lozenges, of sulphur.
Isinglass plaster (English court plaster).
Tartrate of potassium, acid.
Tartrate of potassium and antimony.
Tartrate of potassium, boro-.
Tartrate of potassium, neutral.
Tartrate of potassium and sodium.
Tincture of aloes, simple.
Tincture of aloes, compound.
Tincture of belladonna.
Tincture of stramonium.
Tincture of digitalis.
Tincture of henbane.
Tincture of cinchona calisaya.
Tincture of nux vomica.
Tincture of opium.
Tincture of opium, benzoated.
Tincture of rhubarb.
Tincture of rhubarb, aqueous.
Tincture of rhubarb, vinous.

Valerianate of atropine.
Valerianate of quinine.
Valerianate of zinc.
Veratrine.
Wine of gentian.
Wine of ipecacuanha.
Wine of opium with saffron.
Wine of cinchona.
Wine of opium, compound (black drop).
Vinegar of squills.
Zinc—metallic.

In the case of most of the well-known chemical preparations found in commerce methods of preparation are not given, but simply descriptions and tests.

I will now give some freely translated extracts from the Preface, which will help to show the aim of the compilers, although they may occur in a somewhat disjointed manner:—

"We have only comprised under the title of materia medica those substances or products the use of which in one or more European countries would justify their adoption in an International Pharmacopœia."

"The third division, namely the Pharmacopœia properly so called, raises numerous and delicate questions, such as are not likely to be found in the first and second divisions.

"It is not only necessary to make a judicious choice of formularies well-known and common to all nations, but to eliminate from a vast number of established preparations, more or less empirical or arbitrary in their nature, and which help to compose the special Pharmacopœias of European nations, a selection of remedies which shall meet the general wants of the healing art, and, at the same time, conform to the precise rules which should govern the science of Pharmacology."

"With regard to compound preparations, which result from mixtures more or less complicated, such as syrups, electuaries, pills, mixtures, ointments plasters, etc., it is evident that these compositions, in former times so complicated, irrational, and arbitrary, are now in national Pharmacopœias reduced to a more simple, logical, and scientific condition, and to maintain this principle should be the effort of every pharmaceutist."

The preface contains a long and energetic denunciation of quack medicines or secret preparations so much in vogue both in Europe and America, and puts forth the hope that an International Pharmacopœia, with well-known and approved medicines, will materially tend to diminish the use of these, in many cases, very questionable preparations.

The course adopted by the commission in framing the work is given as follows:—

"The members have first compared with the greatest care the various Pharmacopœias of Europe and America, comprising those of Germany, Great Britain, Austria, Belgium, Denmark, United States of America, France, Greece, Holland, Moldavia and Roumania, Norway and Sweden, and Switzerland.

"This preliminary study was followed by discussion, the result of which was that to each member of the commission was given a share of the work for elaboration; next the work of each particular collaborateur was discussed by the entire committee and definitively adopted for final submission to the judgment of the Société de Pharmacie.

"In the choice and compilation of the various formulæ, the Commission has given preference to those which are most simple, rational, and frequently used, without distinction of origin.

"The Commission, greatly valuing the prevalent ideas of the Codex of 1866, was naturally inclined to propose a number of matters and formulæ taken from the national Pharmacopœia, but it has made it the rule, as a matter of duty, on every occasion where there was a choice between a French and foreign formula almost equivalent, to give the preference to the latter.

"It must be remembered that the work of the Commission is essentially provisional; it is in a measure only a project offered to your appreciation, and the pharmaceutical authorities of each nation are fully at liberty to criticize or combat its propositions, and to endeavour to assert their own special ideas and the methods of their own national Pharmacopœias."

This paper having necessarily extended to considerable length, I will reserve any expression of opinion in detail till the close of the discussion, contenting myself at present by saying that while anxious to give all praise and credit to the compilers of the proposed book for their self-denying and arduous labours, there are still some considerable modifications to be made to adapt it to the tastes and wants of the present age, if it is to be more than in name a Universal Pharmacopœia.

[*The discussion on this paper is printed at p.* 631.]

NOTE ON A SPURIOUS SENNA.*

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

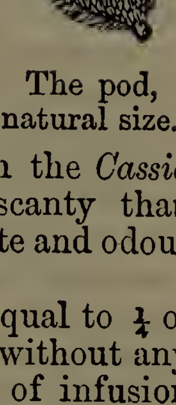
During the past month, a drug has been offered for sale in London, under the name of "fine senna," which evidently differs considerably in botanical characters from the true article, although in size and colour somewhat resembling the Tinnevelly variety. Of this "fine senna" I was informed, when I received a sample, that two bales only were in London, although no less than the enormous quantity of 200 tons was consigned to the agent here, and would probably arrive before long in this country. Hence it appeared probable that this senna might enter into commerce, and that its history and medicinal properties would therefore be worthy of investigation. With this view I examined the few leaves and pod that were first received, and found that they were evidently the produce of a leguminous plant, possibly belonging to the genus *Cassia*, but if so, certainly to a different section to that to which the officinal senna belongs. The genus *Cassia* being an extremely large one, I at once forwarded my specimen to Professor Oliver, who identified it as probably belonging to *Cassia brevipes*, D.C., a native of Costa Rica and Panama. A further supply of the leaves fortunately contained some flowers and young twigs, which were sufficient to enable me to confirm beyond a doubt Professor Oliver's opinion. The sub-genus *Chamæcrista* to which this plant belongs, contains herbs and shrubby plants with pinnate leaves and conspicuous stipules, the flowers being either solitary in the axils of the leaves, or sometimes subfasciculate on a very short common peduncle. There are 78 species in this sub-genus; but the small group of about 9, to which *Cassia brevipes* belongs, consists of plants which are so closely allied as to form an almost continuous series, the leaves being very similar throughout the group. Our plant is, however, distinguished from its con-

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, on Wednesday, February 3, 1875.

geners by its short, very hairy pod, with the hairs golden yellow and not appressed.

The left-hand figure shows an entire leaf with a flower bud in the axil of the leaf. The right-hand upper figure shows the venation of a leaflet, and the small one below it represents a stipule.

The following is a description of the drug I have received:—The twigs above-mentioned have hairy stems, and the leaves are alternate, compound, with a very short petiole, bijugate, and the rachis ends in an extremely fine short hair-like point. The leaflets, which are so closely placed as to overlap each other, are entire, unequal at the base, about 1¼ inch long, somewhat elliptic in outline, the lower margin being less curved than the upper; they are mucronate at the apex. The most marked feature, however, consists in the venation. Three principal veins start from the base of the leaf, and diverging but slightly, proceed nearly to the apex of the leaf. Each of these three veins is branched in a pinnate manner at a very acute angle (about 7°), so that at a casual glance the leaf appears furcate-veined. The two lower leaflets on each leaf are smaller than the two upper ones. The pods are brownish, about twice as long as broad, and covered with yellowish erect hairs. The stipules are lanceolate, with a cordate base, and have numerous minute veins. The flowers are large and yellow, with rigid scarious sepals, and are solitary in the axils of the leaves.



The pod, natural size.

Thinking it probable, since it belonged to the same genus, it might perhaps have the same purgative properties as senna, I made two infusions, one of *Cassia brevipes*, and the other of Tinnevelly senna, each in the proportions directed in the British Pharmacopœia for infusion of senna. In appearance the two infusions were exceedingly different, that of senna being of a rich brown, and the other scarcely darker than almond oil. Both were neutral to test paper, and with acetate of lead, tincture of galls, and solution of perchloride of iron gave similar precipitates, those from the *Cassia brevipes* being rather paler and more scanty than those from the Tinnevelly senna. The taste and odour of both were similar.

Having tried a quantity of infusion equal to ¼ of an ounce of the leaflets, I found it to be without any effect whatever, while a similar quantity of infusion of Tinnevelly senna acted as a decided purgative.

This experiment, however, only proved that *Cassia brevipes*, D.C., is not purgative in ¼ of an ounce doses. I therefore tried the effect of a quantity of its infusion equal to ½ an ounce of the leaves, but with the same result as before. Hence I conclude that this new variety of senna is useless as a purgative, and can by no means replace or enter into competition with the official senna, even if it should be offered at a much lower price; and that should it, hereafter, occur mixed with ordinary senna, it must be looked upon as an adulteration.

[*The discussion on this paper is printed at p.* 634.]

NOTE ON SALICYLATE OF METHYL.*

BY JOHN WILLIAMS, F.C.S.

The recent discovery, by Kolbe, of a method of producing salicylic acid by the combination of carbonic anhydride and hydride of phenyl (carbolic acid), in the presence of caustic soda at an elevated temperature, is not only one of the most interesting discoveries from its theoretical importance, but also for many practical reasons. As an antiseptic the acid promises to be of great importance, and being free from unpleasant taste and quite devoid of smell, and, as far as we know, possessing no poisonous qualities, it will probably be employed for preserving meat, milk, etc., and possibly may be found possessed of valuable preservative properties which may be of value in pharmacy, *i.e.*, in the preservation of infusions, ointments, etc. Of course much will depend upon the price at which it can be produced. At present many practical difficulties in its manufacture have to be overcome, but when the process is better understood, and appropriate forms of apparatus have been devised for conducting the operation, it is expected that the acid will probably be produced at the cost of a few shillings per pound.

It has long been known that the essential oil of wintergreen (*Gaultheria procumbens*) consisted almost entirely of salicylate of methyl. In fact, until lately this oil was the best and cheapest source from which to prepare the acid. It is not much employed by English pharmacists, but in America it is a great favourite, many syrups and preparations of "elegant pharmacy" being flavoured with it.

I have lately prepared some of the salicylate from the artificial acid and find it quite identical in flavour with the natural oil. We thus have the curious fact that a product of the destructive distillation of coal and a product of the destructive distillation of wood combine together to form a natural product, another proof, perhaps, that the time must come when chemists will be able to prepare artificially such bodies as quinine, morphia, or strychnia.

The salicylate of methyl is easily produced by mixing salicylic acid, pure wood spirit (or methyl alcohol), and sulphuric acid together in a retort, and distilling in an oil bath, the temperature required being about 208° Cent.

We may anticipate that it may shortly be produced at a much cheaper rate than the natural oil can be supplied at, and will probably find many uses as a scent in soap-making and perfumery, as well as pharmacy.

[*The discussion on this paper is printed at p.* 634.]

WHAT MAY A DRUGGIST SAFELY SELL?

THE reports upon another page of the proceedings during the past week in the police courts at Hull and Leeds are worthy of the serious attention of all chemists and druggists. They both serve to remind our readers that respectable tradesmen are sometimes liable to the annoyance of being summoned before a magistrate, and to the loss of time and money, for doing only what has been done without let or hindrance literally for centuries. Setting aside for a moment the question whether the arguments put forward in the one case by the Inland Revenue authorities, and in the other by the public analyst of Leeds, are sound, there can be little doubt that preparations of the nature of the "morning tonic" and the "milk of sulphur" in question have been sold by chemists and druggists so long that the maxim "*consuetudo est altera lex*" may be fairly pleaded.

In the "morning tonic" case, which had been adjourned to allow time for the magistrate to consider his judgment, a decision has been arrived at that decides nothing in respect to what is the real position of the chemist and druggist in regard to the sale of such preparations. The magistrate has evaded the difficulty in which he evidently felt himself placed by respiting judgment for six months, with a pretty clear intimation that unless he is compelled by a superior court to deliver judgment the respite will be continued *sine die.*

Nevertheless, a perusal of the remarks made by the magistrate in conveying his determination leaves but little doubt that his opinion leant strongly towards a conviction; indeed, he said that in the facts before him there were grounds for believing that a breach of the letter of the law had taken place, as charged by the Inland Revenue authorities. But that such a breach lies in either of the points instanced by the worthy magistrate we utterly deny. For it cannot be seriously contended that there should be a parody of the "*bonâ fide* traveller" farce, and that the customers of chemists and druggists should be asked whether they are "sick, lame, or distempered" before they are supplied with a medicine which probably is required for somebody else; or that a drug becomes a dram if it be sold in a particular shaped bottle, or if it contain a certain percentage of spirit, or if it be labelled "to be taken occasionally." As to the magistrate's statement, that this last point was disposed of by Dr. KING's objection to a patient being allowed to take a glassful of "tonic" when he chose, we may remark that many medical practitioners would raise the same objection with respect to tincture of rhubarb, but we should be surprised to hear that the Inland Revenue authorities were prepared to claim that tincture of rhubarb was an excisable article on that ground.

In fact, to say that there had been a breach of the letter of the law, seems to us to have been singularly inappropriate. For there was unimpeachable evidence that the article was suitable for a medicine, and that it had been sold as a medicine and used as a medicine. On the other hand, there was nothing more than an expression of opinion that the "morning tonic" resembled some concoctions sold by the publican; but might not the same be said of Mistura Spiritus Vini Gallici, B.P.? In our opinion a justifiable ground for the conviction of a chemist and druggist for selling such a preparation could only be found in the breach of the spirit of the law, by offering facilities for the purchase of drams under the disguise of drugs. And we are glad to find that the Hull case, whether judged by the quantity sold or the fact that a purchaser had to call three times before he could obtain a bottle of it, appears to be free from any appearance of such facilities having been afforded. A cogent answer to the fears of the excise lest the chemist and druggist should compete with the publican is that although, as shown by Mr. SAVAGE last week, the Pharmacopœia of 1747 contained a Tinctura Amara almost identical with publicans' bitters no particular trade in it has been developed yet.

But we venture to go further, and to question the propriety of such a prosecution being commenced without a more intimate knowledge of what a chemist and druggist may or may not sell than is evinced by the prosecutor's admitted ignorance of any tinctures being prepared with spirit above proof. This inability to look beyond certain narrow limits probably led also to the arbitrary choice of representing the spirit strength of the tinctures as equal to so much per cent. of proof spirit. Such a use of a technical term is inevitably misleading, as is shown by the fact that in most reports of this case the word "proof" has been omitted as unimportant. It is obvious that a similar misunderstanding might seriously affect a magisterial decision.

An analogous limitation to preconceived opinions is manifest in the prosecution for the sale of "milk of sulphur," reported on p. 635. The public analyst, starting with the assumption that milk of sulphur is pure sulphur and nothing else, persisted through a long cross-examination in saying that "milk of sulphur" and "precipitated sulphur" were one and the same article, and that the presence of sulphate of lime in the former should be deemed an adulteration. Pharmacopœia formulæ, the opinions of eminent authorities, appeals to the custom of the trade during more than a century,—all were quoted without the slightest effect in the way of moving him from his opinion that when "milk of sulphur" is asked for, whether the customer desires it or not, the chemist and druggist should be compelled to supply precipitated sulphur under fear of a prosecution for adulteration. Of course such a theory could not stand, and at its first collision with practical experience, in the evidence of Mr. BROOKE, it fell to the ground, and with it the prosecution.

The merits of this case are not affected by the question whether the sale of the compound known as milk of sulphur should be favoured by pharmacists. We know there are some who are of opinion that it is the duty of the pharmacist who is asked for "milk of sulphur" to represent it as an impure article or even to substitute the precipitated sulphur without any explanation. But this only has the force of an opinion, and is powerless to affect those who are opposed to it, or to render them liable to legal penalties. In many cases the public prefer, perhaps in ignorance or prejudice, the smooth comparatively odourless milk of sulphur to the stronger smelling and more gritty pharmacopœial preparation. Like Dr. REDWOOD, we do not advocate the use of milk of sulphur, much less its substitution for precipitated sulphur, for this would undoubtedly partake of the nature of a fraud. But whilst the public ask for the compound preparation, and are frequently dissatisfied if they do not obtain it, it is absurd to stigmatize its sale as a breach of the Adulteration Act.

There is an unsatisfactory feature in the initiation of this prosecution which we think is fairly open to censure. Whilst we appreciate the frankness with which the town-clerk withdrew the summons directly he became aware of the true facts of the case, we do not think his apology a sufficient one. It is not much consolation to a respectable tradesman who has had his reputation for fair trading impugned in a police court to be told by the responsible person that his subordinate officers had acted without proper consultation. But we fear that such cases are not at all singular.

We are glad to see that the action taken by the local chemists' associations, in providing for the defence in both these cases, serves well to illustrate the practical value of such societies. The trade at large are indebted to them for the example they have set, and we have also to thank them for their prompt communication of the particulars of the cases.

In conclusion, we would call attention to the fact that the absence of the alkali from soda water is mentioned in the certificate of a public analyst produced in a prosecution at Wolverhampton, although we do not gather from the report whether it had any influence in ensuring a conviction.

THE *Gardener's Chronicle* notices one of those curious mistakes which sometimes occur in attempts to affect a faithful translation of a phrase from one language into another. In this case a French scientific journal, speaking of Owens College, Manchester, calls it "Collége de Saint-Ouen."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, February 3rd, 1875.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Frazer, Greenish, Hampson, Mackay, Owen, Radley, Rimmington, Robbins, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, and Williams.

The minutes of the previous meeting were read and confirmed.

THE MANCHESTER SCHOOL OF PHARMACY.

The SECRETARY read a letter from the Secretary of the Manchester Chemists and Druggists' Association, enclosing the following resolution :—

"That the Council of the Manchester Chemists and Druggists' Association and School of Pharmacy desire to express their warmest thanks to the Council of the Pharmaceutical Society for the grant of £50 in aid of the expenses of the Manchester School of Pharmacy, and trust that the continued efforts of those interested in the School may justify the assistance which has been given to it."

THE BOARD OF EXAMINERS FOR 1875.

The SECRETARY read a letter from the Privy Council Office, approving the appointment of the Examiners whose names had been submitted to the Privy Council, in December.

RETIRING MEMBERS OF COUNCIL.

The lot being taken in the usual manner for the seven members of Council who should retire in May next, the following names were drawn :—

Bottle	Frazer	Hampson
Mackay	Rimmington	Robbins
Stoddart		

The following, who remained in by lot last year, now retire by rotation :—

Atherton	Baynes	Betty
Brown	Greenish	Radley
Savage		

The following remain in office for another year :—

Hills	Owen	Sandford
Schacht	Shaw	Sutton
Williams		

Mr. George Spratt Taylor was appointed Superintendent of the Preliminary Examination to be held in London in April next.

The following being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society :—

Gordon, John.......................... Aberdeen.
McIntyre, Ewen, jun. .... Edinburgh.
Mackay, George Duncan......... Edinburgh.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members of the Society :—

Frazer, Samuel McCall .... Glasgow.
McIntyre, Ewen, jun. .... Edinburgh.
Mackay, George Duncan......... Edinburgh.

Chemists and Druggists.

The following Registered Chemists and Druggists were elected Members of the Society :—

Brown, Alfred James .... Greenwich.
Burn, James .... Flintham.
Foster, James .... Carlisle.
Wright, Edwin Percy .... London.

ASSOCIATES.

The following having passed their respective examinations were elected "Associates in Business" of the Society:—

Minor.

Almgill, John ....Yeadon.
Blacklock, John ....Haslingden.
Holmes, Charles Joseph ....London.
McMillan, James ....Dundee.
McNaught, Archibald ....Greenock.
Nockolds, Stephen William......London.
Pearson, Charles Frederick......Liverpool.
Pidd, Arthur Joseph ....Manchester.
Rees, Samuel Lawrence ... .Hayle.
Robinson, Richard Atkinson ...London.
Symington, Thomas ....Edinburgh.
Wilson, Thomas ....Nottingham.

Modified.

Appleyard, William ....Bradford.
Archer, James ....Lechlade.
Atkinson, Robert John ....Lincoln.
Barge, John ....Plymouth.
Drane, William......................Putney.
Evans, Joseph James Ogilvie ...Teignmouth.
Hannah, John ....Abergele.
Hartley, Stephen ....Harrow-on-the-Hill.
Kirk, Snowden ....Poplar.
Ross, William ....Galashiels.
Scrase, Richard......................London.
Snell, Charles Henry ....London.
Stephen, John Wilson ....Macduff.
Wavell, Edward ....London.
Whittaker, John William ......Rochdale.

The following having passed their respective examinations were elected "Associates" of the Society:—

Minor.

Alexander, Alexander ....Aberdeen.
Bell, Thomas ....Harrogate.
Blackwell, Josiah ....St. Austell.
Cattell, Thomas Bellamy.........Coventry.
Chapman, Walter ....Newstead Grange.
Couper, Charles James............Edinburgh.
Davidson, Alexander ....Insch.
Eminson, Thomas..................London.
Forth, William Pelcher ....Ashford.
Green, Charles Henry ....Hastings.
Haysworth, William Stone ......Preston.
Howard, Robert ....Clitheroe.
Jerrett, Edward.. ....Salisbury.
Kirk, John Robert ....Leeds.
Myott, Frederick ....Oldham.
Newton, Alfred Henry.............Kenilworth.
Price, Charles William.............Abergavenny.
Reade, Joseph George Edward London.
Stephens, George Thomas ......Hereford.
Storie, Robert.........................Edinburgh.
Thomas, Harry Alma ....London.

Modified.

Bingham, Robert ....Hull.
Dodds, John Henderson ....Walsall.
Jackson, William Frazer.........London.
Logan, Francis ....Pembroke Dock.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination were elected "Apprentices or Students" of the Society:—

Adams, John..........................Glasgow.
Alden, Ebenezer Wenham ......London.
Anderson, Edward ....Limber.
Best, John William ....Darlington.
Bilton, John Walter...............Newcastle-under-Lyne.
Bletsoe, Francis Ferriman ......Nottingham.
Boa, Peter ....Stranraer.
Booth, Thomas ....Bolton.
Brayne, John William Ward ...Newmills.
Briggs, William.......................Lancaster.
Broad, Thomas Benjamin ......Macclesfield.
Brook, Charles Mytton ....Saltaire.
Brown, John Jarvey...............Glasgow.
Chapman, Leonard Parker ......Rochdale.
Collins, Robert Enos ....Boston.
Crow, William ....Berwick-on-Tweed.
Dawson, Edward ....New Cross.
Dean, Thomas William ....Linton.
Fry, Henry ....Leicester.
Futcher, Alfred James............Sandown.
Glen, Robert ....Greenock.
Green, Thomas ....Hemel Hempstead.
Holmes, James William ....Norton Malton.
Logsdail, Henry ....Lincoln.
McAlley, Robert ....Edinburgh.
McDougall, Rea Ireland ....Edinburgh.
Marshall, John David ....Boston.
Newbury, Samuel..................Dorking.
Nichols, Frederic Bulstrode......Chelsea.
Ogilvie, William ....Huntly.
Phillips, James Arthur ....Penge.
Railton, William ....Penrith.
Ray, William Frederic............Westerham.
Sandell, John Tyack ....Wellington.
Shrivell, Fredk. Wm. Edward...Hadlow.
Southgate, Wilfrid Burnham ...Hull.
Strachan, John ....St. John's Wood.
Sutcliffe, George Hargreaves ...Bacup.
Swindlehurst, Thomas Newton Preston.
Thornley, Frederick...............Devizes.
Vaughan, John.......................Newtown.
Waddell, Andrew Morrison ...Tollington Park.
Waldie, Robert.......................Innerleithen.
Walker, Robert .... Royston.
Ward, Henry Singleton ....Preston.
Warren, Richard W. ....Leicester.
Watson, Henry Gervase ...... .Sheffield.
Watson, Robert John ....Market Rasen.
Watt, George William... .... ..Huntly.
Weary, China Thomas........... Stoke.
Widdowson, William ....Nottingham.
Wildgoose, John Gratton ......Boston.
Wilkinson, John... ....St. John's Wood.
Wilks, Cuthbert Sympson ......Lincoln.

The following names were restored to the Register:—

Edward, William Wales ... ..Drumnor House, Rhynie, Aberdeen.
Jones, Hugh Lloyd ....227, Brownlow Hill, Liverpool.
Priestman, William ....2, Wellington Street, Waterloo Town, Bethnal Green.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

This Committee made the following recommendation, which was agreed to:—

That £10 be granted to the widow of a registered chemist and druggist, formerly in business at Notting Hill, having four children dependent upon her.

LIBRARY, MUSEUM, AND LABORATORY.

The Committee recommended the purchase of 'Becker's Scientific London' for the library. The attendance in the library during the month preceding the meeting of the Committee had been on the average during the day 12; evening, 9·4. The curator of the museum had reported that the average attendance of students in the museum had been during the day, 10; evening, 3; of ticket-holders, in the day, 3; evening, 1. Professor

Attfield had reported that there had been 68 entries in the laboratory since the commencement of the session, 48 students now being at work.

Mr. SCHACHT drew attention to the inconvenience arising from the rule that only two volumes at a time could be had from the library, especially in cases of works in three or four vols. In such cases he thought the rule might be relaxed.

Mr. GREENISH said it was rather an important question, and he should prefer it being referred to the Committee for consideration before any decision were come to.

Mr. WILLIAMS thought it was very satisfactory to find that so many persons availed themselves of the privilege of using the library. Seeing the Secretary of the North British Branch present he should be glad to hear from him any information as to the attendance in the rooms, library, etc., in Edinburgh.

Mr. MACKAY said he should be very happy to afford any information in his power, but the fact was these matters were attended to systematically down in the north, and statistics collected which were embodied in an annual report. Hitherto this report, though it had been regularly published in the Journal, had not, he feared, received much attention, but as the North British Branch was now coming into some prominence he had no doubt it would be read with more interest. The report would be presented at the end of the session, and would give, he believed, all the information desired.

Mr. SCHACHT asked if it would not be desirable to extend to associates the privilege, or rather the right, of having books from the library. It appeared to him that they were exactly the class of persons whom they desired to assist in this way, and they sometimes found a difficulty at present in obtaining books.

Mr. GREENISH remarked that associates could, he understood, obtain books at present.

Mr. MACKAY said that not only members and associates but registered apprentices also enjoyed the privilege of getting books from the library of the North British Branch.

Mr. SCHACHT said there was a great mistake on the part of himself or his informant, or else on the part of the librarian, if it were the fact that associates could obtain books.

Mr. ROBBINS believed the rule was that associates must apply for books through a member, which sometimes caused them inconvenience.

Mr. WILLIAMS observed that the great difficulty with regard to associates was that some of them so frequently changed their addresses.

After some further conversation the report of the Committee was adopted, and a resolution passed referring the questions brought forward by Mr. Schacht to the Committee.

HOUSE.

This Committee had met to consider what arrangements could be made for the School of Pharmacy Students' Association. Professor Attfield had attended the meeting. It was decided to give the Association permission to use the old Council room for its meetings on Thursday evenings, with the understanding that the Society would be able to use the room if occasion required. Professor Attfield had made a report as to the security of the premises against fire, but the consideration of this had been deferred for consultation with the surveyor.

The report and recommendations of the Committee were adopted.

BELL MEMORIAL SCHOLARSHIP FUND.

A letter from Mr. Daniel Hanbury was read, enclosing a cheque for half-a-year's dividend on the stock invested for the Bell Memorial, and pointing out that in consequence of the death of the late Mr. Waugh the Fund now stands in the names of two trustees only.

Mr. SANDFORD thought it would be well if the stock were transferred to the Society, to be held on the same trusts as its other funded property.

It was decided to consult Mr. Hanbury as to the expediency of adopting this course before any steps were taken.

REPORT OF EXAMINATIONS.

January, 1875.

ENGLAND AND WALES.

	Candidates. Examined.	Passed.	Failed.
Major	3	0	3
Minor	16	8	8
Preliminary	150	64	86
Total	169	72	97

Preliminary: Six Certificates were received in lieu of this Examination:—

1 College of Preceptors.
1 Law Society of the United Kingdom.
1 Society of Apothecaries.
2 University of Cambridge.
1 ,, ,, Oxford.

SCOTLAND.

	Candidates. Examined.	Passed.	Failed.
Major	3	3	0
Minor	3	1	2
Modified	1	1	0
Preliminary	22	13	9
Total	29	18	11

Mr. GREENISH asked if the Secretary could give the relative proportion of candidates who were rejected in London and Edinburgh, because it had been stated that in the latter place young men passed much more easily than in London.

Mr. MACKAY said there could be no objection to the Secretary giving any information in his power upon the subject, but he was glad to say that whatever might be the results, there was now such a reciprocity of communication between the two Examining Boards that there could not be any but the most trifling difference in the two examinations.

Mr. STODDART said he knew of one instance in which a young man who had failed in London went to Edinburgh a month or so afterwards, he believed, and passed. On asking him how it was, he said that the extreme kindness of the Examiners in Scotland encouraged him to give better answers than he could in London. It was evident the young man could not have learned much in the interval.

Mr. WILLIAMS remarked that he understood the rule to be that three months must elapse before a candidate who had failed again presented himself.

Mr. MACKAY said the list of candidates was sent up to London ten days previous to the Examination, for the purpose of being certified, so that no one could come up until the proper time had elapsed.

The VICE-PRESIDENT, as one of the deputation which went to Scotland, desired to bear testimony to the consideration shown to candidates by the Board there, and which he believed was also shown in London. With regard, however, to the Scotch Board drawing out the knowledge of the candidates better than their London colleagues, he might mention one fact which occurred during his presence. A candidate on being asked the very first question, instead of answering, asked leave to be allowed to retire. He (Mr. Bottle) spoke to the young man, who said he was so nervous that he could not answer, and could not, in fact, write his own name, though subsequent inquiry showed that he had written his name on the examination paper in a clear, round hand. He was recommended to retire for a short time and return, but the candidate did not make his appearance again.

Mr. HAMPSON said if it were the fact that a greater proportion passed in Edinburgh in a given time than in London, there must be some reason for it, though what the reason was he could not say. He knew it was the anxious desire both of the Council and of both the Examining Boards that there should be perfect uniformity in the examinations in the two places. Of course the two Boards being constituted of different elements could not be exactly the same, but he was sure the intention was to make the examinations of equal value.

Mr. FRAZER observed that not only was there a difference in the Boards, but also in the candidates. It might be that the cautious Scotch lads took care not to present themselves before they were competent, while the more impulsive English rushed in without caring much for the results.

Mr. SUTTON said he was much grieved to find that at present the degrees of B. Sc. and D. Sc. could be obtained in Edinburgh much more easily than in London. He should be very sorry if any cue were taken from that with regard to the Society's examinations, but he did not think such was the case.

Mr. HAMPSON remarked that statistics, to be of any value, must cover a somewhat prolonged period; it would be quite useless to take the figures for one month for comparison.

Mr. MACKAY said there could not possibly be any difference with regard to the Preliminary, because the questions were printed in London, and only arrived in Scotland by post on the morning of the examination. Therefore, whatever might be the result of the statistics, there could be nothing to cause any difference in the results except in the capacity of the candidates. In the case of the Major and Minor Examinations, it was of course impossible to dictate exactly what questions should be put; but in order that the two examinations in practical chemistry should be assimilated as closely as possible, he had written to the London Board for the various articles used in the laboratory since the change in the examinations in October last, so as to assimilate as much as possible the course pursued by the Board in Edinburgh with that in London.

Mr. BAYNES said this was a most serious question, and he was sorry to find that in his own neighbourhood it exercised a kind of terrorism over the young men, some of whom seemed to be losing their heads over it. He should be sorry if any invidious comparisons were made between Edinburgh and London, but comparing London with London, he found that the percentage of failures had enormously increased.

The PRESIDENT suggested that this state of things was the result of the rule allowing young men under twenty-one years of age to come up for examination. It was already beginning to improve, for at the last examination about 50 per cent. passed, instead of 20 or 30 per cent. as had happened on some previous occasions.

Mr. BAYNES said he excluded altogether the last six months, because there was then an exceptional state of things which would not occur again. He expected to see a gradual improvement take place, but there must never be a race between England and Scotland as to which should pluck most candidates.

The PRESIDENT said such a thing as that could certainly not occur now, because there was constant communication between the two boards who were extremely anxious to carry out a uniform examination.

STATISTICS OF THE SOCIETY.

The REGISTRAR presented a Report showing the present numerical strength of the Society, an analysis of the examinations during 1874, and a statement of the subscriptions to and grants from the Benevolent Fund.

Mr. WILLIAMS said this ought not to pass without an expression of thanks to the Registrar for the care he had displayed in preparing this Report, which he considered reflected great credit on the officials who had been engaged upon it.

Mr. SAVAGE suggested that the consideration of this Report should be deferred.

The SECRETARY said he had no idea of bringing it forward for discussion on the present occasion.

The Report was received and ordered to be entered on the minutes, but not to be published until it had been considered at the next meeting of Council.

PARLIAMENTARY.

This Committee had met, and considered the decision of the magistrate in the Hull "Morning Tonic" case, as reported in the newspapers. The committee were of opinion that the matter should be allowed to drop. (The decision of the magistrate is reported at p. 639).

The Solicitor had reported that Mr. J. C. Swan, of the Household Stores Association, Albert Square, Manchester, who had been proceeded against for using the title of a chemist and druggist, in breach of the Pharmacy Act, had submitted to pay into court a penalty of £5 and costs, at the rate of 20*s.* per month.

THE CONVERSAZIONE.

Mr. WILLIAMS said a motion had been put into his hands that a conversazione be held on Wednesday, the 19th May, and that application be made for the use of the South Kensington Museum on that occasion; but he really thought it was worth serious consideration whether they should hold the Conversazione this year or not. It was a very expensive affair, though it was always very successful, at any rate, so far as the numbers attending it were concerned. He thought there was plenty of time yet for its consideration, and instead of moving the resolution he would give notice of it for the next meeting.

The PRESIDENT thought this would be a good plan, and suggested that the conversazione might be held alternately at South Kensington and on their own premises.

Mr. BETTY said it would facilitate the discussion next month, if the matter were referred to a committee to consider the details in the meantime, and he would, therefore move that it be referred to the Finance Committee.

This was seconded by Mr. Schacht, and carried.

The SECRETARY asked what he should do in the case of a former member who refused to pay his subscription, and who, when applied to to return his diploma, refused to do so.

The PRESIDENT thought the better plan would be to place the case in the hands of their solicitor.

EXAMINATIONS IN EDINBURGH.

January 28th, 1875.

Present: Messrs. Ainslie, Buchanan, Gilmour, Kemp, Kinninmont, Noble, and Young.

Professor Maclagan was present on behalf of the Privy Council during the practical portion of the Major Examination on the 27th.

MAJOR EXAMINATION.

Three candidates were examined. *All* passed, and were declared qualified to be registered as Pharmaceutical Chemists. Their names are as follows:—

*Gordon, John ....Aberdeen.
Mackay, George Duncan..........Edinburgh.
McIntyre, Ewen, jun. ....Edinburgh.

MINOR EXAMINATION.

Three candidates were examined. *Two* failed. The following *one* passed, and was declared qualified to be registered as a Chemist and Druggist:—

Price, Charles William............Abergavenny.

MODIFIED EXAMINATION.

The under-mentioned was examined, and declared qualified to be registered as a Chemist and Druggist:—

Scaife, Samuel ....Manchester.

* Passed in the First Division.

Preliminary Examination.

Erratum.

Page 589, col. 1, line 13 from top, *for* "Doe, James Emile, Atherstone," *read* "Doo, James, Atherstone."

PHARMACEUTICAL MEETING.

Wednesday, February, 3, 1875.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting were read and confirmed. The following Donations to the Library and Museum were announced, and the thanks of the Society were awarded to the donors :—

To the Library :—'Report by Dr. M. C. Cooke on the Gums, Resins, Oleo-Resins, and Resinous Products in the India Museum, or produced in India,' and 'The Flora of British India,' by Dr. Hooker, parts 1 and 2, from the India Museum ; 'How to Work with the Microscope,' by Dr. Beale, fourth edition, 'Bioplasm, an Introduction to the Study of Physiology and Medicine,' by Dr. Beale, and 'Protoplasm, or Matter and Life,' by Dr. Beale, third edition, from the author ; 'Address delivered at the Twelfth Annual Meeting of the Scottish Arboricultural Society,' by Dr. Cleghorn, from the author ; 'St. George's Hospital Pharmacopœia, 1768,' from Mr. R. C. Buckley ; Tarifa Farmacéutica,' from the Sociedad de Farmacia

Argentina; 'On Ergot,' by W. Carruthers, F.R.S., from the author; 'On Winter Cough,' by Horace Dobell, M.D., third edition, from the author; 'Commentary on the British Pharmacopœia,' by Dr. Walter G. Smith, from the author; 'Papers on Leprosy,' by J. C. Lisboa.

To the Museum:—Specimen of Alabandine from Mr. Thomas; specimen of Crystals of Mercuric Iodide, from Mr. C. J. Boorne; specimens of *Plantago Isphagula*, *Juniperus oxycedrus*, *Sinapis juncea*, and *Ipomœa purga*, from Mr. D. Hanbury; specimens of *Gentiana verna*, *G. amarella*, *G. campestris*, and *Antennaria dioica*, from Mr. G. C. Druce; specimens of Anhydrous Phenol and Kosin, from Messrs. Corbyn and Co.; specimen of the fruit of Driâs, from M. Derode, Paris; specimen of the fruits of *Barosma betulina*, from Mr. J. M. Broad; specimen of a new variety of Senna, from the Curator; specimen of False Brazilian Ipecacuanha, from Mr. Allchin; specimen of artificial Salicylic Acid, from Messrs. Domeier and Co.

Mr. Greenish presented, on behalf of Professor Dragendorff, of Dorpat, a number of treatises describing the result of various investigations carried on in the laboratory of the Pharmaceutical Institute, at Dorpat. Mr. Greenish said it had been stated in that room that students did not remain in the Society's School of Pharmacy sufficiently long to undertake original research; their period of study rarely exceeding one session. In the University of Dorpat, original investigations were undertaken by the students during their second session, and the results of those investigations were embodied in theses similar to those now presented upon the application of the students for the degree of "magister" of pharmacy. These theses formed the basis of those exhaustive scientific works which are now issued from the press of Germany. He would be glad to see the highest honours of the Pharmaceutical Society of Great Britain become the reward of original research rather than the result of an examination. He hoped that at some future time there would exist a College of Pharmacy in this country which would grant degrees as the reward of original research.

A paper was then read on—

The Construction of an International Pharmacopœia.

BY FRANCIS SUTTON, F.C.S.

The paper is printed at p. 621, and gave rise to the following discussion:—

Mr. G. S. Taylor asked whether the International Pharmacopœia was intended to supersede existing national Pharmacopœias.

Mr. Sutton said that it was supposed to represent every possible Pharmacopœia which could be produced. It would be a Codex Universel, but though it might be achieved some day it would be many years before that would take place. The product of the French Commission was now before the meeting for discussion, but it would be at least twenty years before the work could be brought to fruition. The principle upon which such a work should be carried out was not a thing upon which that society could decide then. It was a question which must crop up from year to year, and all that the society could do would be to consent to the nomination of a commission for the purpose of preparing an International Pharmacopœia. Pharmaceutists in England had no vote in the construction of the National Pharmacopœia, though he had no doubt that a time would come when they would be associated with medical men in such works, as in foreign countries, where the government deputed pharmaceutists to act in conjunction with medical men in constructing the Pharmacopœias. The present position of English pharmaceutists in this respect was an anomaly.

The President thanked Mr. Sutton for his paper. The subject which he had brought forward was the compilation of an International Pharmacopœia. Whether the work was to be done by English Pharmaceutists or any other persons was another question. With reference to the anomaly referred to by Mr. Sutton, as the British Pharmacopœia was in the hands of the Medical Council by Act of Parliament, until the law in that particular was altered, it must remain so. It would be better now for those present to confine their attention to the subject of the paper which had just been read. He thought he might answer for the pharmaceutists of England that they would do all they could to carry out any International Pharmacopœia which would be useful. It would be many years, as Mr. Sutton had said, before a Universal Pharmacopœia could be adopted; but the communication between the various countries of Europe was now so rapid that it was very desirable that the pharmaceutists of those different countries should agree to the adoption of the same standards of strength for certain preparations, such as tincture of opium and hydrocyanic acid. Only eight years ago there were three different pharmacopœias even in this kingdom, and Mr. Squire put the case very plainly before them in his comparison of the London, Dublin, and Edinburgh Pharmacopœias. They were indebted to him also in this respect, for his "Companion to the Pharmacopœia." If they looked to the last edition they would see, in the case of tincture of opium, for instance, the various differences of strength of that preparation in England, Vienna, Germany, and other places. This showed the advisability of having such a common thing as tincture of opium of one uniform strength. At present, English Pharmacists must help the Pharmacopœia authorities and be as conservative as possible holding to all that was right.

Professor Attfield said that he agreed with the President that it would be undesirable for the discussion to branch off into any question as to who should construct their National Pharmacopœia, though that subject was a very important one. Mr. Taylor had asked Mr. Sutton whether it was proposed that the International Pharmacopœia should supersede all other Pharmacopœias; a question which all chemists and druggists who were interested in the advancement of pharmacy had been asking one another ever since the idea of an International Pharmacopœia had been brought forward. What really were now the aims and objects of the proposed International Pharmacopœia? Did the Congress desire to produce one Pharmacopœia for the whole world; or was the proposed International Pharmacopœia to be a sort of book of reference which a pharmacist would have upon his shelf to consult at any moment, in order to see the extent to which medicines in other countries differed in strength and mode of preparation from those which he was in the habit of using under the authority of his own Pharmacopœia? If neither, then what position would it occupy? The committee entrusted with the preparation of a manuscript International Pharmacopœia had stated most clearly at St. Petersburg what shape they hoped the book would take. The president of the committee wrote a report which was presented to the Congress as coming from the Paris Society of Pharmacy, a translation of which report would be found in the *Pharmaceutical Journal* of September 26th, 1874. In that document was put forward, in unmistakeable language, the desire of the committee on this question. They say, respecting the vote in favour of an International Pharmacopœia at the Congress of 1867, "Did it not show that the moment had come for pharmacists to establish, for medicines and their formulæ, the unity and universality which existed for other sciences, and to transform all the national Pharmacopœias into a universal Pharmacopœia, as they had already transformed collections of recipes or particular formulæ into national Pharmacopœias?" There could be no mistake about that language, and the committee went on to support that view by pointing to the universality of chemical laws and physical laws, and by suggesting that "in all European countries the principles of science and pharmacology are the same." He thought that there could be no question that the desire and aim of the authors of the manuscript Pharmacopœia were to produce such a work as should, at all events ultimately, in future editions, after pharmacists had had for a time "the free exercise of their National Pharmacopœias," supersede all others.

Mr. SUTTON and Mr GREENISH expressed dissent from that view of the intention of the committee.

Professor ATTFIELD said that there might have been a subsequent change of front, but the report most distinctly showed that the committee entertained the idea of "transforming all the National Pharmacopœias into a Universal Pharmacopœia;" and based the idea on the fact that the laws of chemistry and pharmacy, and of science generally, were everywhere the same. In his opinion no Pharmacopœia could ever take up that universal position; for pharmacy, whatever it might become, never could be an exact science. From his knowledge of natural laws he was unable to suppose that one Pharmacopœia could ever become universal. There were differences of climate, of temperature, moisture, and other conditions, which so affected drugs on the one hand and man on the other as to naturally prevent the production of such a work. He would, nevertheless, most cordially support the hope that they might have, sooner or later, a so-called Universal—or, as it had since been termed, International—Pharmacopœia. The indirect good effect of such a book would be immense. With regard to the construction of such a work there could be little or no question about substances which came under the name of definite chemical bodies, and it would be necessary only for them to be mentioned, and, perhaps, their formulæ given, together with a few words of description and some tests relating to purity. With regard to preparations of definite chemical substances and of definite drugs, he could understand that there were many such galenicals which would not differ materially in strength in different countries, and respecting which it would be desirable that one common formula should be selected by the compilers for use in all countries. He agreed with Mr. Sutton that they should thank the committee for their very arduous labours in comparing the different Pharmacopœias with each other, and for their endeavours to produce formulæ which should fairly represent the less important preparations which were used in all countries. But there was a third class of galenicals which were very active, and respecting which great differences of strength prevailed. It was in these that he should hope to see some little deviation from what he understood to be the proposed principles of the construction of the International Pharmacopœia. To make the work useful for the pharmaceutists of all countries, he should like to see the formulæ of such powerful preparations placed side by side, so as to enable pharmacists to compare strength, etc., at a glance, and, perhaps also, by way of preparing pharmacists for some closer approximation of strength in those articles in the future editions. But, before any very close approximation could be made, there must be an interregnum during which they should have for the whole of Europe a book, a portion of which, the portion relating to active galenicals, should resemble the book Mr. Squire produced from the three Pharmacopœias which formerly prevailed in this kingdom, and which doubtless much facilitated the construction of the British Pharmacopœia.

Mr. G. S. TAYLOR asked whether any opinion had been obtained from the British Medical Council with reference to an International Pharmacopœia.

Mr. SUTTON replied in the negative.

Mr. TAYLOR said that he quite agreed with Professor Attfield that there were great and serious difficulties in the way of this International Pharmacopœia; but they had met with difficulties before, and overcome them. If it was desirable that they should have an International Pharmacopœia, he did not see why they should not get over these difficulties as well as others.

Mr. GREENISH said much misapprehension existed in the minds of British pharmacists with regard to one point in connection with the proposed International Pharmacopœia, it being sometimes thought that it was intended to replace all local or national Pharmacopœias. He was not so much surprised at this when he considered that the subject has only recently been brought prominently under their notice. It might be well to commence with the first International Pharmaceutical Congress, which took place in Brussels in 1865. At that congress Great Britain was not represented, and there did not exist in the Society's library any report of its proceedings. The second congress took place in Paris in 1867, when the International Pharmacopœia first assumed a definite shape, and a committee was appointed to draw up a scheme for a Universal Codex. Of the proceedings of this congress, likewise, they had no official report, but in the 'Compte Rendu des Congrès Pharmaceutiques, 1867,' M. Boudet says:—"This Pharmacopœia would not exclude in any way the national Pharmacopœias. It would be a common ground containing the formulæ of medicines which can be used by all nations; and these forms, accepted and consecrated by their assent, would constitute the universal basis of therapeutics." The next congress was that of Vienna, in 1869, where, quoting from the report of the British delegates—for there did not exist in the library an official report of that meeting—he found, "That the Pharmaceutical Society of Paris was engaged in preparing a small work which would contain remedies most generally used in all countries, especially the more powerful, as acidum hydrocyanicum, tr. opii, etc." The next or fourth congress was that of St. Petersburg last year, where Mr. Sutton and himself attended as delegates from that society. On that occasion, in the discussion on this Pharmacopœia, they expressed their opinion that it was "very desirable that in all active medicinal preparations there should be an effort made to establish uniformity of strength," and in their report it was distinctly stated "that each country should form its own Pharmacopœia, but that the congress wished that these separate Pharmacopœias should be based on the principles of the International Pharmacopœia." These principles given at length in the report might be briefly mentioned here,—the metrical system, uniformity of nomenclature, simplicity in names and preparations, the minimum of the active principle of narcotic drugs permitted, and the maximum of impurity in a chemical preparation where absolute purity is not necessary. In the report furnished by Mr. Waldheim, who was president of the St. Petersburg Congress, to the Austrian Pharmaceutical Society, he stated that "the International Pharmacopœia is not intended to exclude national Pharmacopœias." Again, referring to the official report from the St. Petersburg Congress, it was there stated, "The International Pharmacopœia does not exclude the Pharmacopœias of the several countries, yet it is desirable that in the formation of new Pharmacopœias the general principles and directions of the International Pharmacopœia should be adhered to unaltered." It was therefore evident that the International Pharmacopœia was not intended to supersede the Pharmacopœias of the several countries, but would be a condensed Pharmacopœia embodying certain principles which he had just mentioned, and aiming at uniformity in preparations of recognised activity in all nations.

Professor REDWOOD said he had long entertained the opinion that there was a great absence of anything like a clear and uniform idea among those with whom the proposition for producing an International Pharmacopœia had originated, as to what was really the purpose and what would be the utility of such a work, and also what were the best means by which it could be carried out. No doubt the original idea of an International Pharmacopœia was the accomplishment between different civilized nations of that which had already been accomplished between the three parts of this kingdom. We had amalgamated our three national Pharmacopœias into one, and it had been thought, by some probably somewhat visionary speculators, that it would be equally practicable to amalgamate all European and other Pharmacopœias into one work. That opinion, however, as Mr. Greenish had shown, had been put very much out of sight. The bare proposition to supersede all local Pharmacopœias would be likely to set all medical and pharmaceutical authorities, or most of them, against the project. It was therefore thought to be better that they should ostensibly look only to the supplementing of local Pharmacopœias by doing for them what Mr. Squire did for the three Pharmacopœias of the United Kingdom before they were amalgamated. However, the question as to the intention of those who were promoting an International Pharmacopœia still cropped up whenever the subject was discussed. Having heard from those who had come fresh from the congress at St. Petersburg what form the work was to assume, he must confess that he felt disappointed with reference to that point. Mr. Sutton's paper was not calculated to enlighten them much upon the subject. It contained simply an alphabetical catalogue of the names of certain medicines which had been taken from Pharmacopœias from different parts of the world; and he presumed that that list contained the names of all the substances whose formulæ were to be included in the International Pharmacopœia. If so, what was to be the utility of such a work, and what good purpose could it answer? The list was either too much or too little. If, as had been stated by Professor Attfield, it was to supply to pharmacists in different parts of the world the means of interpreting prescriptions written by medical men of other countries, it utterly failed. If, on the other hand, it was intended as a selection of the best medicines used everywhere, it equally failed in that respect, for it did not contain one-tenth part of the necessary medicines employed in this country. The same remark would apply to the medicines of France and other countries. Therefore what possible benefit could result from its publication? He could conceive that some benefits would result from a work which bore the character of an International Pharmacopœia, if it were possible to have a work which would describe the principal and most active medicines which were used in every country, and, if, at the same time, it were possible to induce the medical and pharmaceutical authorities in those countries to adopt one uniform standard with reference to every medicine which bore a specific name. This brought him to what appeared to him to be the only useful and practicable first step towards such an end. Probably one half or three-quarters of the substances which were included in the present list—such as acetate of morphia and acetate of potassium—were needless in such a book. The real object of the work was to instruct those who were dispensing medicines as to the meaning of the terms that were used in ordering them. No doubt could arise in the case of definite chemical compounds such as he had mentioned. What pharmacists needed was to have a definite idea of what was meant by such terms as were applied to galenical medicines, the composition of which was not universally known. The first useful step, therefore, would be to establish something like an international copyright in certain names and formulæ. They must not attempt to apply it, in the first instance, to all galenical compounds; but they might take at first a few of the more active and important, and, when not of a uniform strength, dangerous medicines, such as tincture of opium and hydrocyanic acid, to which the president had referred. A certain list of such preparations might be taken, and if the authorities in different countries could agree to a uniform standard of strength and composition, some good would be effected; and then there should be a law that the names of these articles should be copyright, so that they should apply only to such substances as conformed to the international standard. A dozen substances might be taken to begin with, and the list could be extended from time to time; and in that way they might ultimately attain an agreement between various countries as to the composition of a large number of the more important preparations. As to the establishment of an nternational Pharmacopœia, to supersede all local ones, he agreed with Professor Attfield in believing that it would never be accomplished.

Dr. Farre said that he had come to the meeting under the impression that it was proposed to supersede the existing National Pharmacopœias by a general European Pharmacopœia. He was, however, glad to find that such was not the case. As Professor Attfield had pointed out, although the laws of chemistry and physics were universal, still human constitutions were not alike in all countries, nor the character of disease. Europe embraced an area extending through 35 degrees of latitude, and the medicines and mode of treatment which would be suitable for the inhabitants of the north might not be suited to the inhabitants of the sunny region of the Mediterranean and the half-Moorish people of the south of Spain. He was glad to hear the remarks of Professor Redwood, and he thought it extremely important that there should be some international agreement as to the strength of the more active medicines, such as tincture of opium and hydrocyanic acid. But when he saw such names in the list as phagadenic water and balsam of opodeldoc, he thought that they were dreadfully going back to names which had been long ago given up. He could not help protesting against the use of the Latin language as that in which the International Pharmacopœia should be written. Those persons who were best acquainted with Latin knew perfectly well that it was absolutely impossible to express with accuracy and minuteness, in a dead language, those details and processes which were employed in pharmacy. They had thought when the British Pharmacopœia was drawn up that they had moved a step forward in using the English language. Most of the European Pharmacopœias adopted their own vernacular. As Professor Redwood had pointed out, the greater part of the list of names contained in the paper would be useless in an international work. They need not include definite salts. They needed only to give variable galenical preparations. He noticed that in the list there were no infusions or decoctions, and only two liniments, and a hundred other common preparations were omitted without mention.

Mr. Williams called attention to the curious fact that the list contained no fewer than 33 ointments, and 20 plasters. Again he observed digitalin crystals as one of the ingredients of the work. That was an article which had been prepared by a very clever French pharmacist, but it was not in common use, being rather a luxury, or very special preparation, though the time might come when it would be generally recognized. Altogether the things which were suggested as the ingredients of an International Pharmacopœia were so out of proportion to all that they could suppose to be at present really universal, that the suggestion was at any rate premature.

Mr. Umney said that he noted the absence of ammonio-citrate of iron, ammonio-citrate of quinine, tartrate of iron, and other medicines of that class, which were used extensively throughout Europe.

Mr. Williams added that if the list was to be regarded as containing what French pharmacists considered necessary in an International Pharmacopœia, English pharmacists might congratulate themselves upon being far in advance of the French.

Mr. W. Schacht said that he thought that it would be very desirable to have a universal Pharmacopœia in the sense which Professor Redwood had explained; and he recommended the use of the Latin language in such a work, as it was the only language which would be understood throughout Europe.

Mr. Mackay said that he thought this question was hardly ripe enough for any action to be taken. He coincided with what had fallen from Dr. Farre. If there was to be a Universal Pharmacopœia it must be a very different thing from the list of which Mr. Williams had spoken. That list appeared to him to be the most outrageous and irrational he had ever heard of. As to the language, he thought that Latin ought not to be used. Every country ought to have the Pharmacopœia so plain that those who ran might read. He did not for a single moment mean to argue that it was not a right and proper thing for young pharmacists to be well acquainted with Latin, but he thought it desirable that each country should have such an important work in its vernacular language.

The President again thanked Mr. Sutton for his paper, for it had given rise to a discussion which would set them all thinking. He would suggest to Mr. Sutton and Mr. Greenish, their representatives at the Congress at St. Petersburg, that if they could get the Congress to alter their tincture of opium to that of this country it would be a great advantage, as far as English pharmacists were concerned, and would be a step in the right direction.

Mr. Greenish, in reply to Professor Redwood, said that the formulæ contained in the compilation of the Paris Commission had not been at any time considered by the Congress. The Congress confined itself to the discussion of the principles which should be adopted in the drawing up of an International Pharmacopœia.

Mr. Sutton said that there was no doubt that such a discussion as the present might come on from year to year as an annual thing; but he believed that the idea in the minds of those present who were concerned in the construction of the Pharmacopœia was, that they should simply assimilate those things about the strength of which they were now at variance, such as hydrocyanic acid and other active preparations. Mr. Greenish and himself had talked with pharmacists of several nationalities, and they said that they themselves could only see their way clearly to making a pharmacopœia which would comprise the more powerful preparations, such as those of mercury and so on, and that they regarded anything further as beyond the question.

The next paper read was a—

Note on a Spurious Senna.

BY E. M. HOLMES.

The paper is printed at p. 623, and gave rise to the following discussion:—

The President asked whether the senna described in the paper was already in the market.

Mr. Holmes replied that he understood two bales were in London, and were being offered for sale as fine senna.

The President said that that fact showed the importance of bringing such a subject as this immediately before the Society.

Professor Bentley said that a specimen of this senna had been given to him by one of his pupils, who had received it from a friend living in the country, but how the latter obtained it he was unable to learn. The specimen now described by Mr. Holmes was so unlike the real drug that, he believed, that not even a junior apprentice could be deceived. He thought that there must be some mistake when they were told that the enormous quantity of 200 tons of this spurious senna was on its way to this country; for, supposing the number of pharmacists in this country was 20,000, it would allow over 20 lbs. to each. He did not recollect the quantity of Alexandrian senna annually imported, but the annual importation of East Indian or Arabian senna was only about 100 tons—that is, one-half the quantity now stated to be on its road of the present spurious senna. Professor Bentley said that whoever contemplated sending or importing so large an amount must entertain a very strong opinion of the gullibility and ignorance of English pharmacists, and clearly had no idea how the study of botany had progressed since the establishment of the School of Pharmacy of the Pharmaceutical Society. The best mode of distinguishing the leaflets of the spurious senna from those of the official kinds was by the venation, as described by Mr. Holmes. He did not believe that any wholesale house would be deceived by this senna, and therefore he had no fear of its being sold to any extent in this country in place of the ordinary varieties of senna; the only way in which any amount could be got rid of would be by mixing it with true senna; but even then it could be readily picked out. Professor Bentley suggested to Mr. Holmes that as he had tried this senna and found it not to possess any marked purgative properties, whether it would not be better, to avoid any chance of its being used in place of senna, to describe it as "A New Substitution for Senna," rather than "A New Variety of Senna," which might mislead.

Mr. Holmes said that he had not been able to trace where the senna came from; but there were two bales of it in London. As to the 200 tons, his information was that that quantity would be imported into London, and not that it had already arrived.

Mr. Hanbury said that he had taken a little trouble to find out whether the article which Mr. Holmes described was used for any purpose in any part of the world; but he had been unable to find any mention of its use.

Mr. Holmes said, with regard to the name, that he had called it a variety of senna, because it belonged to the same genus.

Absolute Phenol and Kosin.

Mr. Moss called attention to a specimen of absolute phenol which was exhibited on the table. He said that it was stated to be absolutely pure carbolic acid, and that statement alone would be sufficient to make it interesting. But the chief points of interest with regard to it lay in its physical characters. It was a very coarse powder, made up of very small white crystals, and it might be manipulated as easily as any ordinary crystalline powder, such as common table salt, for example. It was also said to be non-deliquescent, and he had kept it in paper for two or three weeks without finding any trace of dampness in it. Whether it was absolutely non-deliquescent he was unable to say. He thought it highly probable that the claims which had recently been made for using salicylic acid as an antiseptic dressing might be set aside in favour of this pulverulent and faintly fragrant carbolic acid. The chief claims of salicylic acid were its being a fine powder, and having no smell. With regard to kosin he merely adverted to it on account of the paper which had recently appeared in the *Pharmaceutical Journal*. That paper was an abstract of an article written by Professors Flückiger and Buri. In that paper they described kosin as occurring in crystals some millimetres long, and having a sulphur yellow colour. The present specimen of kosin was not in crystals, and it was not of such a yellow colour as had been described. He drew attention to that fact because it was such a specimen as would be offered in trade, and chemists might question its pureness in consequence of its not answering to the description given by Professor Flückiger.

In reply to the President,

Mr. Moss added that kosin was just coming into use.

Salicylic Acid.

Mr. Williams said that Mr. Moss had introduced the subject of salicylic acid, and that was a very important question just now, and was attracting a great deal of interest both in England and on the Continent. It was originally produced from salicyl, as its name indicated, and it was afterwards made from the oil of wintergreen. It had lately been discovered that it might be produced artificially from carbolic acid by the action of carbonic acid in the presence of sodium, or rather, as lately proved, in the presence of caustic soda in proper proportions and at a high temperature—that of 260 C. Half of the carbolic acid passed over, and the other half became converted into salicylate of sodium. This compound was decomposed by an acid, and readily yielded salicylic acid. It was hoped that this substance would in time be produced cheaply and in abundance, and that it would be of great value. He had on the table a specimen of salicylate of methyl produced with artificial salicylic acid. This was not an imitation of the substance, but was the very substance itself. It was really the artificial oil of wintergreen. In this respect it differed from the artificial oil of almonds, for that substance had no chemical identity with the natural oil. This sample of salicylate of methyl was another example of the artificial production of a natural product. Mr. Williams then read a note on the subject, which is printed at p. 624.

Dr. PAUL said that he had come to the meeting for the purpose of putting on the table, on behalf of Messrs. Domeier, a sample of salicylic acid which was prepared in Germany, and it was only half an hour ago that he learned that Mr. Williams intended to put on the table a sample of his own preparation. Much attention was now given to the preparation of this substance artificially. He was glad to see that English manufacturing chemists were not behind the time in following up a new discovery.

Mr. SUTTON said that whilst on the Continent last year he met Professor Kolbe, whose name had been mentioned in connection with this subject, who told him that he had no doubt that by and by they should be able to reproduce by artificial means anything that could be brought forward as a natural product. Of course that was a very strong statement, but he was very glad to see that so far as they had already gone they had this evidence of its truth.

The meeting was then adjourned to the 3rd of March.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The fifth meeting of this Association, session 1874-75, was held in the Library, on Wednesday evening, January 13th; the President, Mr. F. Reynolds, in the chair.

Upon the usual routine business being concluded, the Secretary (Mr. S. Taylor), in a short paper introduced the subject of the "Metric System of Weights and Measures," which prompted a tolerably animated discussion, sustained by the President, several of the members, and a few of the Associates.

The feeling of the meeting was strongly in favour of the system on account of its simplicity, uniformity, and capability of being universally adopted; but the difficulties attending its introduction into this country were also freely admitted. It was suggested by Mr. Geo. Ward, F.C.S., and approved of generally, that if the Pharmacopœia Committee in their next issue of that work would give the quantities of the different formulæ in both the imperial and metric systems of weights and measures, it would greatly facilitate the adoption of the latter by pharmacists, and its introduction into the long-talked-of International Pharmacopœia. A vote of thanks to the Secretary, proposed by Mr. Brown, and seconded by Mr. Jefferson, brought the proceedings to a close.

The sixth meeting was held on Wednesday evening, January 27th, in one of the lecture rooms of the Leeds College of Science, for the convenience of the lecturer, Dr. Thorpe, F.R.S.E., Professor of Chemistry in that college, who read the paper of the evening, entitled "Thomas Graham, his Life and Chemical Work." In opening his lecture, Dr. Thorpe said that those of his hearers who were familiar with Glasgow, would remember seeing in one of its squares, a statue inscribed, "Thomas Graham, born 1805, died 1869," in the execution of which the sculptor had very happily caught the natural expression of the great chemist who by his scientific investigation had contributed so much to the prosperity of that thriving city. The lecturer then rapidly sketched Graham's early life; mentioned his commencing his university studies at the age of fourteen; his attendance at the lectures of Professor Thompson, with whom he was a favourite pupil; the effect of his mother's influence, who fostered his scientific inclinations, as opposed to his father's, who wished him to enter the ministry; his commencing in Glasgow as a teacher; his seven years at the Andersonian Institute, during which he wrote his 'Manual of Chemistry' (used as a standard text-book in Germany); and his call to London as successor to Turner. He then spoke of his selection as first President of the Chemical Society, as also of the Cavendish Society, whose papers have so much enriched chemical literature, and which latter honourable position he occupied till his death; of his appointment in 1854 to the Mastership of the Mint, the practical duties connected with which he conscientiously discharged, notwithstanding the interruption thereby to his literary and scientific pursuits, to which he again returned on relinquishing the office; and of his death, which occurred on the 16th of September, 1869, at the age of sixty-four.

Dr. Thorpe on the present occasion confined himself to one, perhaps the principal subject, of Graham's investigations, namely, that of the diffusion of gases. He first noticed the different theories of the density of the atmosphere; how from an altitude of forty-five miles, as calculated by Wollaston, its diffusibility, as it becomes further removed from the influence of the earth's attraction, has been calculated by recent investigators, and especially by the German, Clausius, to be universal. Its chemical components (not combined but simply mixed) were then given, whilst its uniformity was accounted for on the principle of diffusion. This principle was illustrated by connecting a flask of hydrogen gas with a flask of carbon-dioxide by means of a long tube, placing the flask containing the heavy dioxide at the bottom, and allowing the gases to mix by diffusion; that the mixture had taken place was shown by testing shortly afterwards the interior of the upper flask with lime water, when a white precipitate of calcic carbonate was immediately formed. He next proceeded to explain and illustrate by means of a series of beautiful experiments the diffusion of gases through solids and liquids, mentioning at the outset the accidental discovery by Priestley of the intrusion of coal gas into his tube, whilst experimenting upon steam at an open fire; and in the end impugned the efficacy of S drain pipes and sink traps as preventives against the entrance of sewer gas into houses. The experiments of Graham to discover the rates of the escape of gases, from which was deduced the law that their diffusibility is represented by the inverse square root of their density, were fully expounded. After this the lecturer proceeded to notice the existence of hydrogen in meteoric iron, and the great power of absorbing that gas possessed by the metal palladium, the latter being shown by decomposing water by a galvanic battery, using a palladium point to absorb the disengaged hydrogen, and the whole being reflected on to a blank wall by means of an oxy-hydrogen lantern.

The lecture was listened to by an appreciative though small audience, and at its close a hearty vote of thanks was accorded to Dr. Thorpe.

Parliamentary and Law Proceedings.

IMPORTANT CHARGE OF DRUG ADULTERATION IN LEEDS.

THE SALE OF MILK OF SULPHUR.

On Wednesday, 3rd February, at the Leeds Borough Police-court, before Mr. Bruce, the stipendiary magistrate, John Hellowell, druggist, West-street, Leeds, was summoned for selling on the 19th January as unadulterated half a pound of milk of sulphur, the same being adulterated with sulphate of lime to the extent of 53 per cent. The Town Clerk prosecuted, and Mr. Simpson appeared for the defendant. From the evidence of James Handford, assistant nuisance inspector, it appeared that on the day in question he purchased the above quantity of milk of sulphur at the defendant's shop. Having received the packet he told Mr. Hellowell that it had been bought that it might be analysed to ascertain whether it was adulterated or not. The defendant replied, "I have no doubt it is adulterated, but it is the kind of milk of sulphur that is sold at the shops." Witness afterwards gave part of the packet to Mr. Fairley, the borough analyst. Both the witness Handford and Inspector Newhouse, Superintendent of the Sanitary Department, who was formally called, said they knew there was another commodity called precipitate of sulphur, but neither knew the chemical differences.

Thomas Fairley, borough analyst for Leeds, was examined by the Town Clerk. He produced his report with regard to the milk of sulphur in question. He said the compound was prepared by boiling or heating together sulphur and lime in water. The result of this operation was that the sulphur and lime entered into solution in the water, and by the addition of an acid the sulphur was separated in the form of a powder. If the acid used was sulphuric acid, sulphate of lime was precipitated. If the acid was hydrochloric acid the lime remained in solution, and the sulphur was precipitated unmixed with sulphate of lime. This was according to the instructions given in the Pharmacopœia.

The Town Clerk: What does lime do? Why do you call it adulteration when there is lime?—Because lime is not sulphur.

Does it add to the weight of the material?—It does.

Then if a certain quantity of sulphur was prescribed, and you bought a corresponding dose of this milk of sulphur, you would not have the prescribed quantity of sulphur, but of sulphur mixed with lime?—Yes.

Cross-examined by Mr. Simpson.

Are the constituents mentioned in your report the constituents produced by the ordinary process of making milk of sulphur?—The ordinary process would make milk of sulphur in a fine state.

Is not milk of sulphur omitted from the new Pharmacopœia?—No; it is called by a different name.

Under what name is milk of sulphur denominated in the new Pharmacopœia? If it is included, point out to me where it is?—Precipitated sulphur is included, and I contend that they are the same. They are prepared in the same way by the use of an acid.

Do you mean to tell me, as a chemist, that milk of sulphur and precipitated sulphur are the same thing?—They are.

Was there a time when they were denominated differently?—I cannot answer that of my own knowledge.

Have you read the old Pharmacopœias?—I have read some of them.

In the descriptions in the old Pharmacopœias are there not two distinct substances, one milk of sulphur and the other precipitate of sulphur?—There may be. I don't remember.

But you have read the books?—I don't remember all I have read.

Is it a fact that before the new Pharmacopœia and the new Pharmacy Act, as well as since, there were two such distinct substances sold and used?—There are two distinct substances sold.

And used?—Yes; no doubt they must be used. They are distinct as trade names, but not chemically.

What are they called?—One is called milk of sulphur, and the other is called precipitated sulphur.

And they are two distinct commodities?—Both are sold for sulphur.

Are they two distinct commodities?—In trade they are.

Then so far as you know they are two distinct commodities?—So far as I have heard.

Then if they are, what is their distinction?—I do not know what you mean.

What is the distinction between the two, if they are distinct commodities?—I have not admitted that they are distinct commodities.

Don't you know, as a fact, that they are—that you can go into any shop and ask for precipitate of sulphur or for milk of sulphur, and get either?—I know that that is a custom of the trade, but I am not giving my own opinion when I say so.

Never mind the opinion. There is a custom to provide two commodities called by these different names?—When I say it is a custom in the trade, I should say it is not a universal custom. There are persons who, for the very purpose on which I am now proceeding here, decline to sell milk of sulphur.

Let us know simply what the facts are. I understand you to say that the trade, although not universally, do supply these two distinct commodities, one known as milk of sulphur and the other as precipitated sulphur.

The Town Clerk: The witness does not say so.

Mr. Simpson: Is it true that immense quantities of sulphur are sold as milk of sulphur?—Half of the milk of sulphur is not sulphur. I cannot see that you can call it sulphur when half of it is lime.

What is your knowledge of the trade practice?—My knowledge of the trade is very limited indeed. I know it from conversation simply with persons in the trade, and from observation, and from reading the Pharmacopœia.

Are there not two distinct technical terms for these two commodities?—I do not call them technical terms.

Mr. Simpson repeated the question.—You contend that there are two commodities—

Never mind the contention. The Town Clerk is responsible for that. You are here simply as an impartial official, acting for the public. Are there not two distinct technical terms for these commodities?—There are two separate names with their corresponding Latin equivalents.

Is not lac sulphuris distinctly and separately described in the Pharmacopœia?—It is not there at all. It is the old alchemist's name.

A copy of an old Pharmacopœia was produced, and Mr. Simpson read from it the description of lac sulphuris, or milk of sulphur, stating that it was prepared by boiling sulphur with lime or potash, precipitating by sulphuric acid, and washing the precipitate.

Witness: You have given two different methods of preparing it. The use of bicarbonate of potash would give as a result exactly the same substance as now sold under the name of precipitated sulphur.

You have noticed in that formula I have read that sulphuric acid is used?—Yes.

What would become of the lime after its use?—The lime would become sulphate of lime.

Then what would the potash form?—Sulphate of potash.

How is sulphur præcipitatum made? By using lime and hydrochloric acid?—Yes.

The sulphur is mixed with the lime as in the other case. Can you tell me what the lime does with the sulphur?—It forms a soluble compound.

In both cases that is done?—In the case of sulphur præcipitatum the muriatic or hydrochloric acid forms a soluble compound with the lime.

Then that can be washed away, leaving the sulphur?—Yes, pure sulphur.

Can you tell me why milk of sulphur is so called?—I believe it is so named from its state of mechanical division.

Would not the presence of sulphate of lime in the milk of sulphur prepared by the use of lime make it mix more readily?—Yes, exactly.

Whilst you can scarcely mix sulphur præcipitatum at all?—It is more difficult to mix.

It tends to float on the top?—Yes; but by the use of appropriate means—

Never mind appropriate means. I am talking of the ordinary case of a poor old woman preparing a glassful of it?—In the one case it would require more trouble in mixing it.

Is it not a fact that lac sulphuris makes the water quite milky; the lime present would do that, I presume?—Yes. The same as ordinary plaster of Paris would.

Don't you think, to take the ordinary mode of interpretation, that that is why it is called milk of sulphur, because it presents the appearance of milk?—I don't think that is the reason. Allow me to add that precipitated sulphur is also milky.

Have you known considerable difference of opinion amongst medical men as to whether milk of sulphur or sulphur præcipitatum is the better for the purpose of medicine?—There may be.

You know Dr. Redwood?—Yes.

He is a very eminent man?—Yes.

Have you read his opinion on this subject?—I may have.

Do you know that there has been a strong controversy in the Pharmaceutical Society as to whether milk of sulphur should be maintained as a distinct article of produce?—I believe there has been a controversy.

And that chemists have spoken on each side?—I don't know that chemists have meddled with it.

Is Dr. Redwood not a chemist?—He is more than a chemist.

Perhaps better than a chemist. Is he not a pharmaceutist as well? Was Mr. Morson an eminent chemist?—I decline to say.

You would decline to say whether you have known him as an eminent chemist?—I have seen his advertisements. That is all I know about him.

Have you known him at all?—I have told you. I decline to give an opinion on the qualifications of other persons.

In the debate to which I have referred on this very subject, one of the most eminent speakers said he was far from being prepared to advocate the use of milk of sulphur in preference to precipitated sulphur. But when the presence of a large quantity of lime in the former preparation was brought forward as an imputation against pharmaceutists of selling an adulterated article, he must take exception to such a charge. The same speaker proceeds to say that it was quite possible, but by no means certain, that the pure sulphur would answer the medicinal purpose better?—I should say that it would certainly answer the purpose better.

Having given you this statement as that of Dr. Redwood, will you say, as a matter of fact, that in your experience sulphur præcipitatum would be better than lac sulphuris?—Do you mean within my own experience?

Perhaps you are not a medical man at all?—I have a certain knowledge of medicine. I teach medical students.

Have you any actual knowledge from experience of the effect on the human frame of lac sulphuris as distinguished from that of sulphur præcipitatum?—The only knowledge from experience would be in my own body, and I don't remember having taken it.

The Town Clerk: Then you have none?—No.

Mr. Simpson: Dr. Redwood says it is quite possible, but by no means certain, that pure sulphur would answer the purpose better?—That is Dr. Redwood's opinion, I believe.

But you have no means of forming an opinion. You have never taken it, you state?—Milk of sulphur owes its properties to the sulphur.

Mr. Simpson again read from the opinion already quoted, "When you ask for milk of sulphur you get two things, and it may be the combination is a very good thing. As he had said with regard to another preparation, it was sometimes found that an admixture of foreign matter was far from hindering the action of the remedy, but sometimes rather promoted its efficacy"?—That is merely a general opinion.

No matter; do you agree with me?—I should rather give my opinion the other way.

Mr. Bruce: If lime, mixed with sulphur, were best, would it not be a better way to buy the ingredients separately and mix them?

Mr. Simpson: If you could do it. But if you ask for milk of sulphur you get a combination well known to every chemist in England.

Can you say whether the mixture of this sulphate of lime with the sulphur promotes or affects its efficacy?—I should say it does not promote its efficacy.

Have you any reason for that from experience?—I have only my chemical knowledge.

Have you any knowledge by experience of its effects?—Not of its effects on the human body.

Mr. Simpson (again reading): "They had been accustomed to take a certain quantity of milk of sulphur and expect a certain action from it. It mixed with liquids much better than precipitated sulphur, and he believed that a large number of the public, for this and other reasons, liked it better." There are two distinct commodities—as distinct as you and I—and that being so, I want to know whether you think the ingredient added to the sulphur in this case was likely to do harm. Do you agree with Dr. Redwood on that point?—Before I answer that, it must be decided absolutely whether——

Can you answer the question, Whether the sulphate of lime, mixed with the sulphur, is likely or not to do harm to the person taking it?—I believe it is likely to injure the person receiving it, because if a certain quantity of sulphur is prescribed, and if one half of what is bought for it is lime, then only one-half of the proper quantity of sulphur is received.

Do you agree with Mr. Morson when he says in his general review of what the medical opinion of the country is on the subject, that milk of sulphur does not profess to be pure sulphur?—I believe sulphur in any form is pure sulphur, or ought to be, whether lac sulphuris or sulphur præcipitatum.

Do you agree with Mr. Morson that milk of sulphur does not profess to be pure sulphur?—I believe it to be pure sulphur.

Does milk of sulphur profess to be pure sulphur?—I don't know what you mean.

Mr. Bruce: Would any ordinary medical man or chemist, going into a shop and asking for milk of sulphur, expect to get pure sulphur?—I may say that one medical man has complained to me that——

Mr. Simpson: Answer the Bench. Would a chemist buying milk of sulphur expect to get pure sulphur?—Some chemists would.

And some would not?—Some would not, perhaps. Milk of sulphur may be either pure or not, according as it is made.

Do you know as a fact that many chemists, having tried to substitute the use of precipitated sulphur for milk of sulphur, have failed?—I don't know.

Is it not difficult to substitute it in use even when the difference is explained to the public?—I don't know.

Mr. Simpson (again reading): "Dr. Redwood said, the principle as to pure sulphur was quite correct, if they sold it under the name of precipitated sulphur, but what he contended for was that the two things were quite different. Milk of sulphur was sulphur precipitated with sulphate of lime," and that is the opinion of the most eminent men.—He is not the most eminent man.

Mr. Simpson: Well, he is one of them. He is a great authority in the Pharmaceutical Society.

The Town Clerk: But the witness may not know that.

Do you agree with him, that the two things are quite different, milk of sulphur and sulphur præcipitatum?—I agree that they may or may not be different, according to the way in which they are prepared.

Dr. Redwood says that milk of sulphur is sulphate of lime precipitated with sulphuric acid. Do you agree with that?—That is so according to one of the processes in the old Pharmacopœia.

He says it has long been in general use, and that he did not consider it an adulteration to sell under a distinctive name a preparation which had been found advantageous. —That is his opinion, and I don't agree with it.

He adds that for the same reason complaints might be made of a great many things in the Pharmacopœia, because they have additions made to the original substance, and then that they bear the name of the additions. Do you agree with that; do you know as a fact, but I suppose you won't, that many persons can take milk of sulphur who cannot take precipitated sulphur ?—No, I don't.

I am afraid that you were not at the special meeting of the Pharmaceutical Society, called to discuss this subject. Are you a member ?—No, I am not a member of the Pharmaceutical Society. It is a trade society of chemists who make and compound medicines.

Do you know Mr. Wood, an eminent chemist ?—No.

Do you agree with him or any other person that frequently milk of sulphur can be taken by persons who cannot take precipitated sulphur ?—I have no means of agreeing with that.

Do you agree with Mr. Morson that milk of sulphur is literally a mixture of sulphur and sulphate of lime, and that the sub-division of the sulphur by means of the lime influences its action ; that if any one asked for pure sulphur he would get precipitated sulphur ; but that milk of sulphur was a different thing, which people had a right to get if they wished it, and that he would recommend everybody in the trade to keep both articles, so that either might be had when wanted. You don't agree with that, I suppose ?—No.

Are you a member of the Society of Public Analysts ? —Yes.

Has this question been discussed by that society as to which was the better of the two, milk of sulphur or sulphur præcipitatum ?—It has not been discussed at any of the meetings I have attended.

Did you not attend a meeting, on the 12th December, under the presidency of Dr. Redwood, the very gentleman I have referred to, at Cannon Street Hotel, London ?—No, I was not there.

Do you know Dr. Stevenson ?—Yes. I have met him once.

Is he not a chemist of some position ?—He is a medical officer of health.

Then are you not aware that at this meeting on the 1st December the question of the use of lac sulphuris was considerably discussed ? I suppose you take in the *Chemical News?*—I do ; but I may have omitted that discussion. I have not read it there. I should have made it my business to consult the report if I had thought it was there.

Do you agree with Dr. Stevenson that milk of sulphur is a recognised substance known to chemists as distinct from the substance known as precipitated sulphur. having long been prepared in a different manner ?—They are prepared in very much the same manner.

Do you admit that milk of sulphur is a recognised substance ?—Recognised by whom ?

Don't analyse that word. I mean generally recognised ?—Yes, recognised in the trade.

And known to chemists as distinct from the substance. known as precipitated sulphur. Do you agree with that? —No. I don't agree with that.

Then well known to whom, if it is recognised ?—I don't know what you mean.

You say it is a recognised substance ; known to whom? —Known to persons in the trade.

Are there two things known as milk of sulphur and the other as sulphur præcipitatum ?—They are two distinct names, and both mean sulphur.

Are they not two distinct things ?—They are both sulphur.

Are they not two distinct things ?—I don't hold them to be distinct.

Are there not two distinct things generally recognised under the terms milk of sulphur and precipitated sulphur ? —I don't call them distinct.

Are they not two things ?—They are both sulphur ; no matter, if you ask me till Doomsday. I cannot call them distinct.

You have told me already that milk of sulphur was a recognised substance. Don't you know that it is used for animals as well as for human beings?—Many of our medicines are.

Mr. Simpson : That is no answer to my question.

Witness : If you say it is so used, I don't dispute it.

Do you know it of your own knowledge ?—I think it is very likely.

Mr Bruce : Was there an antiquated preparation called milk of sulphur, made in the way first described ?—Yes ; and it is there in the old Pharmacopœia.

And that old preparation was omitted from the new Pharmacopœia?—Yes.

And in its stead was substituted sulphur præcipitatum ?

Mr. Simpson : No, sir. Sulphur præcipitatum existed before.

Mr. Bruce : Was the sulphur præcipitatum substituted for the old milk of sulphur ?—The milk of sulphur was dropped out.

This concluded the evidence in support of the summons.

Mr. Simpson then addressed the court in opening the case for the defence. He said, the Pharmacy Act had no relation at all to this question. The question was whether this drug—milk of sulphur—was adulterated, and the issue raised by Mr. Fairley was that milk of sulphur should never be sold again ; that no longer should we have this preparation, but that on all occasions sulphur præcipitatum should take its place.

Mr. Bruce : He says that a milk of sulphur can be made which would keep within the legal line.

Mr. Simpson : But how does that help the matter ?

Mr. Bruce : One of them leaves a large foreign ad mixture, and the other does not.

Mr. Simpson : That may be so, but *cui bono* if a man wants pure sulphur let him ask for sulphur præcipitatum. Assuming that milk of sulphur is producible by two different processes, if he goes for milk of sulphur and wants sulphur pure, he must designate by which of the two processes he wants it. If he wants sulphur alone, why ask for milk of sulphur ? For the prosecution to make out their case, they must prove that the officer Handford did not get what he asked for. There were five kinds of sulphur : sulphur nigrum, sulphur rotundum, lac sulphuris, sulphur sublimatum, and sulphur præcipitatum. Lac sulphuris, or milk of sulphur, had never been known in the trade as pure sulphur, and any person going into a shop and asking for it ought to know that the practice in the whole of the trade was to supply a certain compound. The question was whether the thing which the man had asked for, and which was supplied, answered to the denomination of milk of sulphur. According to Mr. Fairley, one process of making milk of sulphur ended in sulphur præcipitatum, and he said the two articles were identical, but in cross-examination he had been forced to admit that in the trade milk of sulphur was recognised as an independent thing. Sulphate of lime, which formed part of the compound milk of sulphur, was rather beneficial than otherwise, because it was well known by chemists that sulphate of lime had a disintegrating effect on the sulphur, and in the human body it caused the sulphur to act, and produced the laxative consequences which were intended. He had to do, not with Mr. Fairley's opinions, but with what the public required. Was he to be told that when a man went into a chemist's shop and asked for milk of sulphur, he did not want it prepared with sulphate of lime ? And was it to be that milk of sulphur prepared with lime and sulphuric acid was to be blotted out of the Pharmacopœia ? Milk of sulphur was not a pure drug. It was not sulphur. It was a combination and a preparation. On behalf of his client, who was supported in his defence by the Chemists' Association of the town, he contended that milk of sulphur was a known commodity, which was made in a certain way, and sold in a certain state, and that therefore when a person asked for it, he got the article which was sold as milk of sulphur ; and as far as the defendant was concerned, he supplied his customer with the article which was asked for, for sulphur præcipitatum was not lac sulphuris. The Act under which the prosecution had been instituted was not intended to apply to such simple things as that, which really had no injurious consequences to the health of the community.

Thomas Brooke was then called as a witness for the defence. He said he was a partner of the firm of Hirst, Brooke, and Hirst, manufacturing chemists, Leeds. During his 20 years' experience milk of sulphur had been known in the trade as an article prepared by mixing together lime, flowers of sulphur and water, and precipitating with sulphuric acid. He had never known any prepared with bicarbonate of potash, nor had he ever known milk of sulphur without the presence of sulphate of lime. Under the term "milk of sulphur" sulphur would not be sold without sulphate of lime in it. Precipitated sulphur was known in the trade as a distinct thing, the difference being that it was pure sulphur, and milk of sulphur was not pure sulphur. When they wanted milk of sulphur, his firm ordered it in that name or as lac sulphuris from the maker, getting an article prepared with lime and precipitated with sulphuric acid. So far as the public use of it was concerned, there was a preference for milk of sulphur over the precipitated sulphur; in fact, there were cases in which the latter had been tendered and the customers had brought it back and would not have it, but wished for the milk of sulphur, because it would mix better with water. He had not the slightest reason to form an opinion that milk of sulphur had any deleterious effect when taken as a medicine.

The Town Clerk: Is not this milk of sulphur sold largely for manufacturing and trade purposes?—Not that I am aware of.

The Town Clerk stated that with the evidence before the court he should not be justified in seeking for a conviction, and in justification of himself he had to say that the information had been laid by the officers of the Corporation without any previous consultation with him, and that he had never heard of the case until that morning. He mentioned that, because he should have wished to have had an opportunity of advising upon the case, and he hoped a similar error would not be made again.

Mr. Bruce said that after hearing Mr. Brooke's evidence and the comments of Mr. Simpson, he thought the Town Clerk had exercised a wise discretion in withdrawing from the prosecution.

The summons was then withdrawn.

Mr. Simpson asked for costs, which were allowed.

THE SALE OF "MORNING TONICS" BY CHEMISTS.

On Tuesday, at the Hull Police Court, Mr. Travis, the stipendiary magistrate, gave judgment in the case of Mr. William Stanning, chemist, who was summoned for a breach of the Excise laws. Mr. Travis's finding was as follows:—

The defendant in this case is a chemist, who is charged on the part of the Board of Inland Revenue, under the 6 Geo. 4, c. 81, s. 26, with dealing in or selling or retailing spirits without taking out the required licence entitling him to do so, the penalty for such an offence being £50. By a subsequent statute, 23 & 24 Vict., c. 114, s. 148, the word "spirits" shall include and mean all mixtures and compounds, preparations or commodities, into the manufacture of which spirits enter as the basis or principal ingredient. The Acts to which I have just referred must, however, be read in conjunction with another Act passed in the 16th Geo. 2, intituled "An Act for repealing certain duties on spirituous liquors, and on licences for retailing the same, and for laying duties on spirituous liquors, and on licences to retail the said liquors," by which (chap. 8, sec. 12) it is provided that that Act shall "not extend to any physicians, apothecaries, surgeons, or chemists as to any spirits or spirituous liquors which they may use in the preparation or making up of medicines for sick, lame, or distempered persons only." The 16th Geo. 2, c. 8, was repealed by the 30 & 31 Vict. c. 59, except only the part of the proviso of sec. 12 which I have just read. The defence set up by the defendant in this case must (to be available) be that he is protected by the proviso referred to, and that the spirits which he is charged with selling unlawfully were used by him in the preparation or making up of a medicine for sick, lame, or distempered persons only. The evidence shows that on Oct. 1, 1874, Mr. Claridge, an officer of Excise at Hull, went to defendant's shop in Cogan Street, and there saw the defendant. Claridge asked for a bottle of "pick-me-up," and was told defendant had none made, and on calling again defendant said he had not got it filtered, but defendant went into an adjoining room, out of Claridge's sight, and after being absent a little while, brought a bottle from the room and gave it to Claridge, charging him 3*s.* 6*d.* for it. Claridge did not say anything about size, and knew nothing about there being three sizes of bottles varying in price from 1*s.* to 2*s.* 6*d.* and 3*s.* 6*d.* The bottle was of the kind generally used for hock, and would hold a *reputed* quart, but it was not quite full. The contents of the bottle, on being analysed, were found to contain 67 per cent. of proof spirit, only 3 per cent. of solids, and ash 2 per cent. The flavour appears, according to Mr. Harkness, who analysed it, to be derived from gentian, orange peel, and probably a little quassia. The same witness states that it is similar in every respect to the public-house bitters. On the part of the defence it has been stated that the "pick-me-up" contains ten or twelve ingredients, but I have no evidence before me as to the actual contents of the bottle of "pick-me-up" bought by Mr. Claridge and afterwards analysed, as the defendant's son was away from home for twelve months prior to the latter end of September, 1874, and states that there was no "pick-me-up" made between his return and October 1st, though he says what there was in stock, kept in a large carboy, was similar in taste to that sold to Mr. Claridge; but Mr. Harkness' opinion as to the identity with the Hull "pick-me-up" and public-house bitters would not be altered unless he knew the exact quantities of the ingredients, as there might be only a trace of some of them. Mr. Harkness also states that the "pick-me-ups" are sold as medicines, and that the chief constituents of medical "pick-me-ups," are gentian and quassia, and that they contain 10 per cent. of solid matter, while the Hull "pick-me-up" contains only 3 per cent. The son of defendant says that none of the tonic or "pick-me-up" was made in September, after his return, and before October 1st; and he states that it is three weeks or a month after being made, and is not in a fit medicinal state before that time. If this be correct it is difficult to understand the course pursued by the defendant, who told Claridge the first time he called that he had none, and the second time that it was not filtered; for the son swears distinctly that the tonic is not in a fit medicinal state for three weeks after being made, whereas Claridge got it after a trifling delay, when, if only just made, it could not be, according to the son, in a fit state to be taken as a medicine. The label has on it "Morning Tonic." It is also stated on it that a small glassful may be taken at any time, and intimates that its being mixed with sherry will make it more palatable. The defendant has called several medical witnesses, against whose testimony no objection can be taken so far as it goes, but it may be well questioned whether it bears sufficiently upon the points at issue to have the value that, coming from such gentlemen, it might otherwise be entitled to. Drs. King, Gibson, and Walton, would none of them prescribe the tonic, assuming it to contain what is alleged, as they prefer using more simple remedies, but if made up of all the ingredients named they would call it a medicinal preparation—and one of them said a very nasty one, though he had not tried it when mixed with wine, as mentioned on the label. A good deal of evidence was given to show that certain tinctures are much stronger than the Hull "pick-me-up," but it was also shown that their use was carefully regulated, and it was attempted (I think in vain) to be shown that the label on the tonic was much the same as the directions of a physician, that a medicine should be taken occasionally. Dr. King however disposed of this entirely by the expression of disapproval of the permission of the label to take a small wineglassful of tonic at any time a patient liked, while Dr. Gibson states that a small glass is a little over a dose, and taken once a day would not be hurtful, but taken three times a day it would be deleterious from the drying nature of the tonic, and we may presume—though Dr. Gibson was not asked on that point—that the effect could hardly be expected to be more beneficial (in a medicinal point of view) if taken with wine to make it more palatable. The evidence of most respectable parties was adduced to show that they had used the tonic as a medicine and derived benefit from it, but this does not show that it is a medical preparation within the proviso in the 16th Geo. II. c. 8, sec. 12, but is equally consistent with its being a compound in which "spirits" enter as the principal ingredient, the sale of which is prohibited except where a licence is obtained. This is in truth all that was really proved by the evidence for the defendant. To obtain an exemption from the penalty fixed by the statute under which this charge is made the defendant must be shown to come clearly within the proviso of the 16 Geo. 2, which confines the cases for exemption within narrow limits and to those cases only, and the *onus probandi* lies upon a defendant. While each case must (of necessity) be adjudicated upon on its own facts, and it may be fairly asked, from the evidence adduced, can it be said the defendant has shown that the spirit of which the "pick-me-up" was—to the extent of 67 per cent.—composed, were used in the preparation or making up of medicines for sick, lame, or distempered persons only? Did the defendant use any means to discover for whom or for what purpose it was required, or that it was required by those to whom only the proviso applied? Did he believe that Mr. Claridge was sick, lame, or distempered? Why did he think it requisite, without asking any question, to give the largest sized bottle? the only reason that can be inferred for doing so being that the 3*s.* 6*d.* bottle is the cheapest to the purchaser, and that defendant on that account only gave him it instead of a smaller bottle? Is the label consistent with the sale of a carefully prepared medicinal compound for sick persons only? On the other side, it may be fairly urged that if the sale of this compound is an infringement of the 6th Geo. 4, c. 81, it is singular that some intimation of the views of the Inland Revenue authorities should not have been made during several years the defendant admits he has been in the habit of selling the "pick-me-up," unaware that any objection, legal or otherwise, could be taken to his doing so. It may also be fairly contended that the very fact that medical gentlemen of high standing have come forward and stated that the "pick-me-up" in their opinion may be termed a medicinal preparation, might well account for the defendant taking a similar view, and have led him to a somewhat hasty conclusion that being in one sense a medicinal preparation it necessarily becomes exempt from the operation of the 6th Geo. c. 81. Other causes might be adduced, tending to show the *bona fides* of the defendant in the course he pursued in this case, but still, looking at the whole of the evidence carefully, I am of opinion that public-house bitters and the pick-me-up of Mr. Stanning are *ejusdem generis*, and partially identical; and further that though in the construction of a very stringent Act of Parliament evidently intended to confine the exemptions to the narrowest possible limits (demanded by necessity and humanity), there are upon the facts before me many grounds for insisting that a breach of the letter of the law, as charged by the Inland Revenue authorities, has taken place. I should be extremely reluctant, unless required to do so by legal authority, to carry out such a conclusion, as I cannot think that this is a case that ought to be pressed against the defendant; nor do I think it is one where it would be satisfactory or just to inflict a fine, especially the heavy fine named in the Act of Parliament under which this charge is made. Under the circumstances, the position of the respective parties having been duly considered, and having gone into the matter fully, the defendant will not be liable for anything beyond his own costs, and I trust the ends of justice will be considered to be fully met by my respiting judgment for six months, and also that such respite may be practically *sine die.*

The Sale of Soda-water.

At the Wolverhampton Borough Court, on Tuesday, Jan. 26, Thomas Smith, soda-water manufacturer, was charged with having sold six bottles of soda-water as pure although subsequently found to be adulterated.

Mr. E. W. T. Jones, the borough analyst was called and said that the soda-water in question was handed to him by the inspector, and after examining it, he gave the following certificate:—"The title under which this sample was sold is quite a misnomer; it is an anomalous specimen altogether, containing no carbonate of soda, and hence devoid of the valuable properties peculiar to genuine soda-water. Carbonate of lime is present in considerable quantity, and it shows traces of copper. I consider it is an adulterated article and injurious to health."—In reply to the Bench, witness said lime salts and copper were injurious to health.—In cross-examination witness stated that he also analysed a sample of ginger beer purchased from the defendant, and he found that to be genuine. If the defendant used pump water, or any kind of hard water, in the manufacture of his soda-water, that would account for the large excess of lime and salts, and if he used tap-water for his ginger beer, that would account for it being free from such adulteration as alluded to. If the vessel used for the charging of the water with the gas were a brass one, that would account for the presence of copper.

In defence, it was stated that the defendant used hard water because he believed it made better soda-water, and was not aware that it contained such an excess of lime-salts as Mr. Jones had stated. After what had been stated he would take care in future not to use hard water, and also to use a silvered vessel.

A penalty of 40s. and costs was imposed.—*Midland Counties Evening Express.*

In consequence of the space taken up by the official and legal reports, we are compelled to defer the publication of several communications.

FURTHER NOTE ON THE BOTANICAL SOURCE OF JABORANDI.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

In the 65th fasciculus of Martius' great work, the 'Flora Brasiliensis,' containing the *Rutaceæ*, by Engler, —only recently published and received in this country during the present week,—three new species of *Pilocarpus* with pinnate leaves are mentioned, viz.:—*P. Selloanus*, Engl., *P. grandiflorus*, Engl., and *P. macrocarpus*, Engl. Of these, the description of *P. Selloanus* answers to the smooth variety of the Jaborandi of Pernambuco much more nearly than that of *P. pennatifolius*, Lem.

From the following analysis of the pinnate-leaved species copied from the above work, it will be noticed that the author separates the species with smooth leaves from those with hairy leaves; hence, if this arrangement be accepted, the hairy variety of the Pernambuco Jaborandi must belong to a distinct species:—

B.—Leaves imparipinnate, 2-6 jugate.
- *a.* Leaves smooth on both sides.
  - *P. Selloanus*, Engl.; leaves 2–3 jugate. Pedicels slender, six times longer than the buds; ovary smooth.
  - *P. grandiflorus*, Engl.; leaves 6 jugate. Pedicels thick, scarcely longer than the buds; ovary densely ferruginous-pilose.
- *b.* Leaves shortly pilose beneath, especially on the nerves.
  - *P. pennatifolius*, Lem.; leaves 1–3 jugate. Leaflets linear; oblong midrib; and lateral veins prominent beneath.
  - *P. Goudotianus*, Tulasne; leaves 1 jugate and unifoliate. Leaves large, obovate or lanceolate-oblong, midrib only rather prominent beneath.
  - *P. macrocarpus*, Engl.; not sufficiently known.

The following is a translation of the diagnosis of *P. Selloanus*:—

"*Stem* covered with thin purple bark, leafy towards the apex. *Leaves* imparipinnate. *Petiole* of leaf semiterete, flattened a little above, quite glabrous. *Leaflets* trijugate, oblong, distinct, nearly equal, obtuse, margin reflexed, membranaceous or subcoriaceous, greyish green, quite glabrous on both sides, pellucid punctate; midrib sulcate above, very prominent beneath; lateral nerves rather prominent beneath; petiole of leaflets short. *Raceme* terminal, nearly three times longer than the leaves, terete, purple, quite glabrous, with slender pedicels horizontally patent and slightly hairy, six times longer than the buds and furnished at the middle and base with two minute ciliolate bracts. *Calyx* very short, with broad rounded lobes, which are ciliolate. *Petals* coriaceous, lanceolate, acute, furnished with a prominent midrib, inflexed at the upper margin and at the apiculus. *Stamens* shorter than the petals. *Ovary* depressed, globose, very smooth, half included in the disk, and crowned with a short, rather thick style."

The figure represents the leaves as being slightly emarginate. In the *greyish green* leaves, *slender* peduncle and pedicels, and smooth fruit, *P. Selloanus* agrees with the Jaborandi plant; but the pedicels of *P. Selloanus* are longer and hairy; this, however, future specimens of Jaborandi may perhaps prove to be of no importance.

P. pennatifolius, Lem., is described as having *bright green* leaves, hairy on the veins beneath, and a thick peduncle with short thick pedicels. So far, therefore, as the most recent researches on this genus have made known the species, Jaborandi must be said to approximate more nearly to *P. Selloanus* than to *P. pennatifolius*, Lem.

COD LIVER OIL WITH QUININE.

BY M. H. STILES.

Twelve years ago, in a paper read before the Pharmaceutical Society, Dr. Attfield called attention to the fact that the natural alkaloids combine with oleic acid to form oleates which are soluble in oil.* Although he particularly instanced quinine, and suggested that the oleate of quinine would be a convenient medium for the preparation of "cod liver oil and quinine," I do not think the method has been adopted to any considerable extent.

I lately had occasion to prepare some cod liver oil with quinine. I employed what I believe to be the usual process, precipitating the alkaloid with ammonia, and, after washing and drying, dissolving it in pure ether, then mixing this ethereal solution with the oil. The customer, a lady, quickly returned it, having a very strong objection to the taste of the ether.

I therefore tried the plan of preparing the oleate and dissolving that in the cod liver oil, and found it perfectly satisfactory.

The preparation may be made as follows:—

Take of Sulphate of Quinine	60 grains.
Diluted Sulphuric Acid . .	1 fluid dram.
Solution of Ammonia	a sufficiency.
Distilled Water	a sufficiency.
Purified Oleic Acid	1 fluid ounce.
Cod Liver Oil	29 fluid ounces.

Dissolve the quinine in the diluted sulphuric acid mixed with 4 oz. of water, add a slight excess of ammonia, stir well, transfer the whole to a calico filter, and after carefully washing the precipitate, press it between folds of bibulous paper and dry it by the heat of a water-bath. Dissolve the quinine thus obtained in the oleic acid by the aid of a gentle heat, mix the solution whilst warm with 5oz. of cod liver oil also warm, strain through cotton wool or filter through paper if necessary, then add the remainder of the oil. The product should measure 30 fl. oz.; each table-spoonful (fl. ℥ss) contains oleate of quinine equal to one grain of sulphate.

The above preparation has the characteristic taste of quinine and cod liver oil, the oleic acid from its small amount not being perceptible.

A sample prepared two months ago has kept well, being quite clear, and as free from deposit and objectionable odour as on the day it was made.

Whilst writing on this subject, I may remark that I am surprised more attention has not been given to the production of ointments and oleaginous liniments containing the oleates of aconitia and atropia. I believe that these preparations would be more certain and uniform in their effects, and therefore more reliable, than the corresponding liniments of the Pharmacopœia.

Hull, January 28th, 1875.

THE EMPLOYMENT OF COAL OILS IN THE PREPARATION OF ALKALOIDS, ETC.*

BY G. BOIRAUX AND E. LÉGER.

On the occasion of presenting a report on crystallized aconitine and digitalin to the French Academy of Medicine some time since, M. Boudet called attention to the fact that the industrial preparation of alkaloids had almost entirely passed from the hands of French manufacturers. This he attributed to the heavy duties payable upon alcohol in France, and suggested that either there should be a remission of the duty upon spirit used for such purposes or that an attempt should be made to prepare the alkaloids without the intervention of alcohol. M. Boiraux was hence induced to make numerous experiments, in the course of which he found that the oils obtained by the destructive distillation of coal are good solvents of a great number of alkaloids, and that they have the advantage over alcohol of having but little action upon the extractive, and giving at once nearly colourless solutions of the alkaloids; consequently it becomes unnecessary to have recourse for purification to repeated re-crystallizations and animal charcoal.

The sudden death of M. Boiraux just at the conclusion of his investigation prevented him from publishing his results, but his friend, M. Léger, who had assisted in many of the experiments, has described from M. Boiraux's notes the details of the processes for preparing several of the alkaloids. In a foot-note the Editor of the *Répertoire de Pharmacie* states that the MS. was accompanied by some remarkable specimens of the products of these processes.

The bodies which dissolve in coal oils are not all susceptible of being deposited in a crystalline form upon the evaporation of that solvent; and it is better to pass even those which do possess that property into an acid liquor, and afterwards precipitate. Certain fatty and resinous matters are thus removed, and the product is perfectly white. A certain number of alkaloids, such as strychnine and cinchonine, are insoluble or only slightly soluble in coal oil, and the solubility varies according to the nature of the oil employed. In the preparation of quinine sulphate, the heavy oils, *i.e.*, those which pass over the last in distillation, are exclusively employed, they having a solvent power much superior to the lighter products, which was found to be due solely to the presenc of phenol. This fact having been ascertained, it suggested whether the addition of carbolic acid to ordinary coal oil would accomplish the solution of the bodies insoluble in coal oil alone. The experiment was successful; coal oil mixed with five per cent. of carbolic acid dissolves strychnine and cinchonine in considerable quantity in the cold, but does not affect morphia.

The solvents employed in the investigations were—(1) the oils boiling between 50° and 100° C., and known in commerce as benzol; (2) that portion of the oil which passes over between 80° and 120°; (3) the preceding, with the addition of 5 per cent. of carbolic acid.

It is important that the vegetable substances or precipitates be carefully dried before submitting them to the action of the oil, because coal oil does not soften, and consequently cannot dissolve a substance already impregnated with water.

Atropine.—For the preparation of this alkaloid the authors recommend the use of an aqueous extract of the dry leaves and benzol as a solvent.

Aqueous Extract of Belladonna . .	500 grams.
Soapmakers' Ley	125 „
Benzol.	4 litres.
Distilled Water	q. s.

The extract is placed in a porcelain capsule surrounded by cold water, and the caustic soda added gradually, the whole being well stirred so as to thoroughly mix the extract with the alkaline liquor. Soon after this addition the matter liquefies and becomes heated, and it is to avoid this effect as much as possible that the capsule is kept cool. Sufficient distilled water is added to bring the extract to the consistence of a thick syrup, and it is then poured, a portion at a time, stirring well after each addition, into a vessel having a capacity of 3 litres and containing 2 litres of benzol. After standing for a quarter of an hour the liquor separates into two perfectly distinct layers; the benzol charged with the atropine being at the top, and the solution of the extract underneath. The first layer is decanted, and the solution of the extract is poured, with the same precautions, into another vessel containing the remainder of the benzol. The two layers of benzol, containing all the atropine, are united; then shaken with a mixture of 5 grams of sulphuric acid in 75 grams of distilled water, and allowed to stand, the liquor being afterwards separated by filtration. The benzol is then shaken a second time with 2 grams of sulphuric acid in 25 grams of water. The two aqueous solutions, which contain all the atropine in the state of sulphate, are then united and introduced into a flask, and the caustic soda added drop by drop until a precipitate is no longer produced. It is well shaken during ten minutes with 100 grams of well rectified benzol. A large proportion of the atropine set free by the soda passes into the benzol, which is decanted off, and the alkaline liquor agitated with 50 grams of fresh benzol. This removes the whole of the remaining atropine, the alkaline liquor becoming limpid. The reaction may be facilitated by placing the mixture in a water-bath at a temperature not exceeding 30° C. By these different treatments the whole of the atropine from 500 grams of extract is obtained in 150 grams of liquid. This is filtered through white paper, and evaporated in a small glass retort, by means of a water-bath, to one half; the residue poured into a capsule soon deposits the atropine in long, perfectly white, silky needles. When the crystallization takes place over a large surface, handsome stellate groups are formed.

The extract of belladonna employed is prepared by macerating the entire leaves in cold water during two days, straining and washing the residue with more water until the water passes colourless; the liquor is then evaporated in the usual manner. Expression of the substance and the employment of heat are avoided so as to remove the least possible quantity of mucilaginous matter, which otherwise during the treatment of the extract with benzol forms a sort of gelatinous emulsion which is very persistent. It is important that the consistence of the mixture of extract and alkali should neither be too thin nor too thick. The alkaline extract should be poured into the benzol in a thin stream. The authors also caution against the rinsing of the last of the extract from the containing vessel into the benzol by means of water, as the addition of a small quantity of water will emulsify the whole mass. The quantity of atropine obtained from 500 grams of extract is about 3 grams. As 1 gram of pure atropine is

* *Répertoire de Pharmacie*, vol. ii, p. 377.

soluble in 50 grams of cold benzol, it might appear that the quantity of benzol used (4 litres) is excessive, but it is that which has been found best to prevent the emulsion, and also desirable because of the large proportion of insoluble matter through which the atropine is diffused. The benzol may be used for successive operations without rectification.

Santonin.—One kilogram of whole semen contra is boiled during half an hour in a copper vessel with 5 litres of water and 250 grams of lime, then thrown upon a strainer, and strongly pressed. A second decoction is made with 3 litres of water and 150 grams of lime, and a third with 2 litres of water and 100 grams of lime, after which the semen contra is exhausted. The united products form a liquid coloured strongly yellow by a resin peculiar to the semen contra, and rendered turbid by the lime in suspension. This liquid is rendered freely acid by the addition of sulphuric acid, and then allowed to settle during twenty-four hours, after which time the precipitate, which consists of santonin and sulphate of lime, and weighs after desiccation about 500 grams, is collected on a filter. The calcareous precipitate, finely pulverized, is now placed in a vessel with a litre of coal oil and heated in a water-bath, with occasional agitation, during half an hour, to a temperature of about 80° C.; the whole is then thrown upon a filter, and the marc is washed with half a litre of coal oil, also previously heated. The liquid being coloured yellow by the resin, it is again placed in the water-bath with 20 grams of powdered animal black, by which it is completely decolorized in about a quarter of an hour. The apparatus is then removed from the fire, and after letting the vessel stand in the water-bath some time, for the animal black to deposit, the liquor is poured upon a filter sufficiently large to allow of its rapid filtration and to prevent the deposition of the santonin upon the filter. Upon the cooling of the solution nearly all the santonin is deposited in colourless crystals. By concentration of the mother liquor the remainder of the product may be obtained, but it is preferable to preserve the oil for subsequent operations.

The slaked lime employed is obtained by treating caustic lime with the quantity of water strictly necessary to produce the hydrate CaHO. Lime is the only alkali that can be used for the purpose; soda and potash have so energetic an action that the semen contra is completely dissolved. Lime has the further advantage of forming with the sulphuric acid an insoluble salt, which, carrying down the resinous matter and santonin, furnishes a fine powder that is easily treated. The semen contra must be used whole; for when used in powder it swells up and forms a magma that it is impossible to liquefy. The object of letting the decoction stand twenty-four hours after it has been treated with sulphuric acid, is to give time for the santonin to deposit, because the santoninate of lime is not immediately decomposed by acids.

Pure santonin is only slightly soluble in cold coal oil, but when mixed with the resin its solubility is considerably increased. If the yellow solution of santonin at first obtained be distilled until reduced to 150 grams, the crystals are several days in forming. But if animal black be added it seizes the resin, and the result is that the santonin is deposited as the temperature rises, until when it approaches 50° or 60° C. the liquid forms a mass. This induces the authors to think that in the semen contra a part of the santonin is combined with the resin; but only a part, because the direct treatment of the semen contra with coal oil removes a small quantity of santonin.

Veratrine and Delphinine.—To prepare veratrine 500 grams of powdered sabadilla seeds are moistened with diluted soap makers' ley, and kept during two days in a closed vessel, then dried in a stove. The product is next treated with boiling coal oil in a displacement apparatus until a litre and a half of percolate is obtained. This is placed in a tubulated retort with a solution of 5 grams of tartaric acid in a litre and a half of water, and distilled over a sand bath until there remain only about 500 or 600 grams of a nearly colourless liquid containing the veratrine in the state of tartrate, surmounted by a small quantity of fixed oil that has escaped the action of the caustic soda. After cooling, the liquor is filtered through moistened paper, and then precipitated with ammonia. The veratrine is deposited perfectly white as a very abundant magma containing much water; it is drained and then dried.

By this process, ten grams of pure veratrine are obtained from a kilogram of seeds.

Delphinine is easily prepared by operating in exactly the same way upon staphisagria seeds.

In moistening the powder with the alkaline liquor it is preferable simply to stir the mixture with a wooden spatula and not with a pestle, as it agglomerates and becomes excessively hard in drying, and thus requires a second pulverization. The caustic soda forms with the fixed oil present in sabadilla in considerable proportion a soap insoluble in benzine; any excess is converted in the air into carbonate and, efflorescing, facilitates the desiccation of the powder. Besides combining with the fatty matter it assists in separating the veratrine from its combination in the seeds.

In distilling equal volumes of coal oil and water at first coal oil alone passes over, water passing over in increasing proportions as the temperature rises. When all the oil has been distilled off about one half of the water remains in the retort.

(To be continued.)

RIVERS POLLUTION COMMISSION.

(*Continued from p.* 608.)

Pollution by Baryta Mines.—Sulphate of baryta is frequently associated with galena in lead mines, but as this compound is insoluble in water it does not possess the poisonous attributes belonging to all the soluble salts of baryta. Sulphate of baryta is a nearly worthless mineral (its chief use being for the adulteration of white paint), and is never mined for its own sake, but carbonate of baryta has important applications in chemical industry. Carbonate of baryta is, in respect of running water, one of the most dangerous minerals mined in this country; fortunately, however, injury to water can in this case result only from gross carelessness; but if carbonate of baryta be stamped or ground with galena or other ore, the preservation of neighbouring streams from poisonous pollution would be much more difficult.

Pollution by China Clay Works.—Generally speaking the effluent water from clay pits is polluted only by suspended matters, and these, after complete subsidence in settling pits, leave the water sometimes even purer than before its use for clay washing. Unfortunately, however, the effluent water from clay works is rarely allowed to subside completely. Thus the white stream from the Gazelan works still retained in 100,000 parts, 251·6 parts of suspended matter, which is, however, innocuous to animal life.

River Pollution arising from Metal Manufactures.—At the outset of the investigations, it appeared probable that the extensive manufacturing operations carried on in Great Britain in connexion with the metal trades, inclusive of metallurgy, would present numerous instances in which refuse of various kinds would be cast into running water. The Commission has, however, now arrived at the conviction that, with the exception of the pollution caused by one or two metal trades, the rivers of this country suffer in an insignificant degree from operations of this character, in comparison with the frightful damage which is inflicted upon them by the sewage of towns and by the drainage from factories devoted to the various branches of industry connected with textile fabrics. This comparative harmlessness of most of the metal trades arises; firstly, from the circumstance that most of them are carried on with but a very slight use of water; and secondly, because waste products arising from metals rarely contain organic matters, which by their fermentation and putrefaction so seriously affect not only the water but also the air.

The metallurgical operations, or the processes for extracting the metals from their ores, carried on in Great Britain are, almost without exception, chemical operations by the dry or hot method, in other words, smelting operations; the extraction of nickel from its ores being the only notable exception, consequently their prosecution has very little effect upon rivers and streams.

The chief if not the only nickel work in Great Britain is the large factory of Messrs. Evans and Askin in Birmingham. The ores of nickel, most of which also contain cobalt, are imported to these works from all parts of the world. Some of these ores contain the metal in the form of sulphuret, others in that of arsenuret, and others again as oxide. Some regulus or concentrated sulphuret of nickel, obtained by a preliminary smelting, is also imported. These ores and regulus are mixed together and melted in reverberatory furnaces. The earthy portions are converted into slag, which is run off and used for repairing roads. The metallic portion is worked up to a regulus containing from 50 to 60 per cent. of nickel and cobalt. This regulus is first roasted and then dissolved in acids, and the different constituents are separated and utilized. The nickel and cobalt are separately precipitated with milk of lime, and the residual solution of chloride of calcium is allowed to run into the neighbouring canal. The Commission was informed that this was the only liquid refuse from these works. The other waste products are utilized or sold as marketable commodities. The arsenic contained in such portions of the ores as are arsenical is transformed into arsenious acid in the roasting operation, and is discharged into the air amongst the products of combustion. The analysis of a sample of the only waste liquor issuing from these works proved that it contained no copper, nickel, or cobalt; it consisted of solution of chloride of calcium. The inspection of these nickel works left no doubt that the processes of manufacture can be, and are easily carried out, without offence to running water; but it was also evident that the reckless or careless prosecution of the nickel metallurgy might give rise to river pollution of considerable intensity.

Pollution by Iron and Steel Wire, Tin Plate, and Galvanizing Works.—Of all forms of river pollution arising from industries connected with the working of metals, that produced by the discharges from iron and steel wire, tin-plate, and galvanizing works is the most intense, noxious, and notorious. In all these operations iron, either in the form of wire or sheet, is steeped or "pickled," as it is technically termed, in dilute sulphuric or muriatic acid; there is thus formed a solution of sulphate of iron (green vitriol) in the one case, and of chloride of iron (muriate of iron) in the other. Muriatic acid seems to be selected chiefly because it is slightly cheaper in some localities. The dilute acid is employed to dissolve oxide of iron from the surface of the metal, and as it requires to be of considerable strength to effect this, there is always left in the bath, when it is practically exhausted, a large proportion of free acid. There is also in solution a larger proportion of sulphate or muriate of iron; the first a product of some value, and easily disposed of, the second a compound of considerable repute as a disinfectant, but for which there is only a variable and uncertain market. It is the general practice, however, in these works to discharge the waste contents of the acid baths suddenly into rivers or sewers, rendering the water of the former unfit for many manufacturing purposes, and for the support of fish life, greatly damaging the brickwork of sewers by the corrosive action of the free acid, and in some cases rendering their contents unsuitable for irrigation without previous purification with lime. In some cases, too, considerable inconvenience is caused by the corrosive action of the acid water upon the interior of steam boilers.

Pollution by German Silver and Electro-plate Works.—The metal known as German silver or nickel silver is an alloy of copper, nickel, and zinc, or it may be described as brass alloyed with nickel, which latter metal is distinguished by the whiteness of its alloys, those containing a considerable proportion of nickel almost rivalling silver itself in lustre and absence of colour. The alloy is, however, essentially base metal, and it is easily corroded by dilute mineral acids and even by vinegar. To protect its surface from such action, it is usually coated electrolytically with a film of metallic silver or gold. Hence the manufacture of German silver is usually combined with that of electro-plating. One of the largest factories of this description is that of Messrs. Elkington and Co., at Birmingham. German silver articles, before being finished or electro-plated, are pickled for a short time, sometimes in dilute nitric acid and sometimes in dilute sulphuric acid. After long use these acids become more or less saturated by the metallic constituents of the alloy; but as the metallic salts thus formed are valuable, they are never thrown away in well-regulated factories. The only metalliferous discharge from such factories is the water in which the articles are washed after their removal from the pickling vats. Samples of this water in which articles from the nitric acid bath and from the sulphuric acid bath had been washed were submitted to analysis, the results showing that several of them were of a highly polluting character; but the more concentrated, containing as they do considerable quantities of valuable metallic salts, are never allowed to escape from well-regulated works, whilst the waste water used for washing the pickled articles contains but moderate proportions of polluting materials, and may be admitted into the sewers of towns with impunity.

Remedies.

In considering the subject of the proper remedies for the evils described in this report, the Commission deals first with the abuses of running water arising from mining operations which fall naturally under three categories: (1) Injury to river channels caused by the casting of solid rubbish into them; (2) Pollution of water by suspended matters; (3) Pollution of water by dissolved matters.

The injury to river channels caused by the casting of solid rubbish into them, the Commission thinks can be very easily prevented by an enactment forbidding it under adequate penalties. It is quite true that there are many lead mines, some tin mines, and some coal pits which now find an easier discharge for their useless quarry stuff, waste shales, and skimpings owing to the neighbourhood of a convenient river channel, than they will have if this doorway of escape for these waste materials be closed. But, as the Report very properly points out, the fact that the mine owner has to incur considerable expense in order to find standing room for his waste products, is not to be regarded as an injury inflicted on the property which he possesses; it is merely proof that the property he holds is not quite so valuable as he may have supposed that it was. He has no right to encroach either on his neighbour's land or on the river channel which affects his neighbour's land, simply because it would be extremely convenient for him to do so. It is incumbent on him to bear the expense, whatever it may be, which is required in order to prevent the injury which at present he inflicts on either. If land is to be had only at a distance, he must elect between the cost of building his waste material higher on his own land, and the expense of carrying it that distance.

Pollution of Water by Suspended Matters.—Soon after commencing the inquiries into the mining operations carried on in this country, it became evident that the standard of purity recommended to be enforced in former reports could not be enforced against polluting liquids from mines without inflicting undue hardship upon these branches of industry.

The extraction of the ores of lead, tin, zinc, and manganese from their rocky matrix, necessitates, in most cases, the stamping and crushing of both ore and rock to an almost impalpable powder, which must then be submitted to the action of a copious stream of water in order to separate as much as possible of the valuable ore from the worthless rocky matter with which it is mixed. The suspended matters carried forward by the water in such operations frequently require a very long time to subside, whilst their character is such as to render the filtration of the water practically impossible, owing to the rapid choking of the filters by the fine suspended particles.

The only other available method of purification is subsidence; but, unfortunately, the finer portions of the suspended matter often subside with such extreme slowness as to render it very difficult for miners to comply with the standard which prescribes that in 100,000 parts of the discharged water there shall not be more than three parts of mineral matter in suspension. To test this point an extensive series of experiments was made upon the turbid waste waters collected as they flowed from the dressing floors of various mines. These samples, after vigorous shaking, were placed in glass cylinders one foot deep, and the time required for complete subsidence was noted. It was found that the effluent water from tin mines could be purified so as to bring it within the limits of pollution allowed by the suggested standards, by the simple process of allowing it to rest for six hours in a settling pond before discharging it into the river. The muddy water flowing from iron mines, coal pits, and coal washing floors requires a much longer interval of time, varying from 44 hours to 22 days. The length of time required for the similar clarification of the foul water from lead mines varies from 44 hours to as much as 61 days. Mines of this description could not therefore be brought within the limits prescribed by the suggested standard relating to mineral matters in suspension without inflicting great expense upon iron, coal, and lead miners, and consequent serious injury on those branches of mining industry.

Having arrived at this conclusion it became important to ascertain how far a reasonable amount of subsidence would suffice to mitigate the great evils at present complained of in mining districts. With this end in view a fresh series of experiments was instituted, in which samples of mud, collected from the beds of various streams, were submitted to fractional subsidence.

The results of these experiments point to a very simple and inexpensive, though unavoidably imperfect, remedy for the chief form of mining pollution.

It would seriously interfere with the mining industry of this country if a standard relating to suspended mineral matter, so stringent as that which has been found easily practicable in other branches of industry, were enforced against discharges from mines. Whilst the Commission believes, however, that subsidence as complete as desirable could not practically be applied to such discharges, their inquiries show that a very moderate amount of settlement, say six hours, would remove a very large proportion of the noxious matters from the water.

For the realization of this salutary result, however, it is absolutely necessary that the subsidence of six hours should be of a *bonâ fide* character. Little of the advantage just recorded would be gained if a stream, however slow, were allowed to flow through the settling ponds. Subsidence is enormously hindered by even the slightest movement of the body of water in which it is taking place; and hence it is that, although in numerous cases subsidence ponds are provided in connexion with dressing floors, ostensibly for the purpose of preventing river pollution, in no single instance has the result been satisfactory, owing to the universal neglect of this precaution.

Efficiently to carry out the remedy recommended, it will be necessary to provide storage for at least as much muddy water as is produced in eighteen hours. This storage should be divided into three ponds, two of which should be alternately used, whilst the deposit in the third is being drained, dug out, and removed to a position from which it cannot be washed into the neighbouring streams. The alternating ponds should be used in the following manner:—The muddy water to be run into pond No. 1 for six hours, the exit being completely closed; and the stream then turned into pond No. 2 for the same length of time. After five hours of perfect rest the discharge of pond No. 1 may be commenced by lowering a wide sill, so as to allow the surface water to the depth of, say three inches, to flow away. The sill is to be gradually lowered so as to complete the discharge within an hour, and care must be taken that it is not so far depressed as to permit the escape of any of the deposited mud. The sill being again raised, the pond is ready to receive a second charge of muddy water, whilst the contents of pond No. 2 are undergoing subsidence. The ponds may be of any depth, but in order to insure adequate subsidence of their contents, the depth of water run off in discharging them ought not to exceed five feet.

Only in a very few of the largest establishments does the quantity of water passing through the slime pits of any mine amount to 400,000 gallons daily; a quantity which would need for its treatment in the manner as recommended three subsidence tanks capable of holding 100,000 gallons each; or, if eight feet deep, with five feet of available depth for subsidence, each 100 feet long and forty feet wide. The three tanks required in these maximum examples would thus not much exceed one quarter of an acre in total area.

(*To be continued.*)

THE PREPARATION AND CHARACTER OF ELATERIN.*

BY FREDERICK B. POWER, PH.G.

A handsome specimen of elaterium was obtained, which a preliminary examination showed to be free from the adulterations sometimes present, and to contain no substances foreign to the drug itself. Fifty grains were exhausted with boiling alcohol, the resulting solution thrown upon a filter, the filter washed with a little boiling alcohol, and the filtrate evaporated by a gentle heat; while still warm, it was poured into a warm dilute solution of potassium hydrate, whereby most of the resin was retained in solution, whilst the elaterin gradually precipitated, upon cooling, in small crystalline crusts or grains.

The amount of elaterium dissolved by the boiling alcohol was sixty per cent., and seven grains of elaterin were obtained, which still required to be purified from the adhering green resin that clings to it with considerable pertinacity, and interferes, both by retarding crystallization and diminishing the beauty and purity of the product.

The impure elaterin was collected, thrown upon a filter, washed with cold water, and redissolved in boiling alcohol. The solution still possessed a greenish hue, and was agi-

* From the *American Journal of Pharmacy* for January.

tated with petroleum benzin, which absorbed the resin, and upon the separation and evaporation of the liquids, the elaterin, in beautiful colourless needle-shaped crystals, and the remainder of the resin were obtained separately.

The advantage of benzin for the removal of this resin is very apparent, since the use of ether, which has been previously suggested and employed for the accomplishment of this purpose, is much less preferable in point of economy; it also dissolves a portion of the elaterin, and thereby causes a considerable loss, while by the use of benzin no appreciable amount of elaterin is dissolved. It is believed that, by taking advantage of this fact, treating the elaterium first with water to remove the inert substances soluble therein, treating the residue with boiling alcohol, and subsequently with benzin, the green resin may be completely removed without resorting to the use of the alkaline solution, thereby considerably modifying the usual process and rendering the preparation much more expeditious. The amount of material at the writer's disposal would not admit of any extended experiments in this direction.

A small portion of elaterium was boiled for two hours with dilute sulphuric acid (one part of acid to ten of water), which almost entirely dissolved it, forming a nearly colourless solution, and frothing quite strongly upon agitation, while a few resinous flocks remained insoluble, which, upon separation, were soluble in alcohol, with a yellowish-red coloration.

The filtered acid solution in behaviour to an alkaline solution of cupric oxide and caustic potash, gave evidence of the presence of glucose, although the failure to obtain this result with elaterin induces the writer to believe that *pure elaterin* is not a glucoside, and that in instances where a reduction of the cupric oxide takes place, it may be attributed to the impurities which may be present.

According to Zwenger (*vide* Gmelin's 'Handbook of Chemistry,' vol. xvii., page 365), "Elaterin is insoluble in dilute acids and alkalies, and does not precipitate alcoholic solutions of metallic salts, although aqueous solutions of metallic salts precipitate elaterin from its alcoholic solution in the same manner as water. It dissolves in oil of vitriol with dark red colour, and is precipitated from its solution as a brown substance by water."

The writer observed the following behaviour toward reagents:—If a crystal of elaterin be placed on a porcelain plate with a drop of concentrated sulphuric acid, a deep red colour is instantly produced, which is one of its most delicate tests; if a small fragment of potassium bichromate be then added, it changes to a deep brown, and ultimately to a light green. As salicin and other substances, however, produce a red coloration with sulphuric acid, this test alone cannot be relied upon, unless attended by other and confirmatory results. Its solution in concentrated sulphuric acid becomes carbonized upon the application of heat. With hydrochloric acid no change of colour takes place, either in the cold or upon heating, and it is apparently insoluble in that liquid.

If a drop of strong nitric acid be added to elaterin upon a porcelain plate, no change of colour takes place, except after standing for several hours, when a pinkish tinge is observed; but upon heating it with that liquid a red coloration is soon produced, with the evolution of nitric oxide vapours, and upon the addition of water white flocks separate.

Elaterin undergoes no change of colour with chlorinated alkalies. An alcoholic solution of elaterin is not precipitated by an alcoholic solution of tannic acid or barium chloride. When heated, it melts, giving off white fumes, which are neutral in their action upon litmus, and burns with a smoky flame, leaving a garnet-coloured, resinous ash.

A prescription was recently received for one grain of elaterin, to be dissolved in a fluidrachm of water, for hypodermic injection; but being wholly insoluble in water, no practical method could suggest itself to the mind of the writer whereby such an application could be obtained.

CINCHONA, OR CHINCHONA?

In his recently published 'Memoir of the Lady Ana de Osorio, Countess of Chinchon,' Mr. Clements R. Markham has revived the discussion of a question which, so far as preponderance of practice can determine anything, might now be supposed to have been satisfactorily settled. It is whether the orthography "Chinchona" or "Cinchona" should obtain for this now famous genus. Reserving for a future opportunity a criticism of Mr. Markham's book, we briefly indicate here his views upon this subject.

There can be no doubt that Linnæus, in naming the genus, sought to connect with it the name of the lady who is reputed to have first made the healing virtues of the bark known to Europe. Whether he was well acquainted with the lady's name is not so clear. Mr. Markham thinks he was not, but that he received his knowledge of the Countess of Chinchon through a French source, and was thus misled into calling the genus *Cinchona* in the 'Genera Plantarum' of 1742. He further thinks that Linnæus showed his uncertainty by the orthography *Cinhona* which occurred in the edition of 1764, but that he died before the error was pointed out and corrected. Mr. Markham sums up his arguments by stating that all authorities agree that "Chinchona" is correct, and that consequently "Cinchona," "Cinhona," and other forms are wrong; that the object sought of commemorating the services of the Countess is defeated by the mutilation of her name; that in much of the most important literature of the subject the word is spelt "Chinchona," and lastly that "the correct spelling should be universally adopted because it is right." He also quotes the following botanical authorities, who have explored the native forests of the genus, as spelling the word correctly:—Pavon, Ruiz, Tafalla, Mutis, Zea, Caldas, Seemann, and Spruce. Finally, with a chivalric admiration of the "illustrious and beautiful lady, Ana de Osorio," which is manifest throughout the book, Mr. Markham pleads that the correct spelling may be retained as the only way by which the "memory of her who made known to the world the inestimable value of quina bark" may be preserved.

On the other hand it has been contended that Linnæus purposely omitted the *h* for the sake of euphony, and that the law of priority must obtain; that botanical names are means, not ends, and their use as means once established it is all but impossible to alter them. Further that "Cinchona" has been so universally adopted that great inconvenience and confusion would result from any attempt to substitute "Chinchona" for it.

Apropos to this discussion, Mr. Hanbury has taken the opportunity of investigating the introduction by Linnæus of the genus *Cinchona*, and has pointed out that the misspelling of the name of the Countess occurs in several authors much earlier than Linnæus. He also proves that Mr. Markham is far from correct in asserting that the Spanish botanists, one and all, support the mode of spelling he (Mr. M.) advocates; but that, on the contrary, Mutis, as well as Ruiz and Pavon, follow the orthography of Linnæus. Mr. Hanbury's strictures are contained in the *Athenæum* of Jan. 30, and are as follows:—

"In connection with Mr. Markham's proposal in his 'Memoir of Lady Ana de Osorio,' reviewed in the *Athenæum* of the 23rd of January, that botanists should abandon Linnæus's word *Cinchona* (Sinkona) in favour of *Chinchona* (Tshin-tshona), and, as I presume, that doctors, pharmacists, and chemists should do the same, and that the reform should extend to the words *Cinchonine*, *Cinchonidine*, and *Cinchonicine*, as well as to any other derivations from the word *Cinchona*, may I be allowed a few remarks on the origin of the Linnæan name, and on some of the arguments used by Mr. Markham to support his case?

"It may be at once conceded that *Chinchona* is a word which better commemorates the Countess of Chinchon than does *Cinchona*.

"But let us trace the introduction of the genus Cinchona by Linnæus, and for this purpose let us have recourse to the actual volumes which formed part of the library of the great botanist, and are, many of them, enriched with his MS. notes. They are now in the possession of the Linnean Society of London.

"In an interleaved copy of the 'Systema Naturæ,' published in 1740, there occurs in the section 'Pentandria Monogynia" a memorandum in Linnæus's hand, after the genus Genipa,—'*Quinquina Cond.*' This is the first allusion to the tree discovered by La Condamine, and on which Linnæus founded the genus.

"In 1742 appeared the second edition (*aucta et emendata*) of the 'Genera Plantarum,' and on one of the two pages of Addenda (p. 527) is the following sentence:—'In Pentandria monogynia post Genipam, Num. 168-1021, Cinchona. Quinquina *Condamin* Act. Gall. 1738.' In the 'Ordo Generum,' the name is again printed Cinchona, and so likewise in the index.

"In the fourth edition of the 'Systema Naturæ,' published at Paris in 1744, we read at p. 30,—'Cinchona. *Quinquina.* Cond. Le Quinquina,' and the same spelling is adopted in the editions of 1748 and 1756. Again in the fifth edition of the 'Genera Plantarum,'—'*ab auctore reformata et aucta,*' which appeared at Stockholm in 1754, the spelling of the controverted word is again (p. 79) Cinchona, and so it is in the 'Species Plantarum,' of which the first edition was printed in the previous year (1753).

"From these quotations, it may be fairly assumed that Linnæus fully meant to use the word Cinchona, and that its occurrence as '*Cinhona*' in one solitary instance in the sixth edition of his 'Genera,' 1764, was a mere typographical error, and not, as Mr. Markham seems to think, a proof that he desired to spell the word correctly.

"'It was still more unfortunate,' says Mr. Markham, 'that Linnæus died before the error was pointed out and corrected. This was done by the Spanish botanists, Ruiz and Pavon, who landed in Peru in 1778, the very year of Linnæus's death. They explored the forests of Huanuco and Loxa, discovered many new species of *Chinchonæ*, and are among the highest authorities on the subject. They strongly advocated the correct spelling. . . . The botanist Mutis, with his disciples Zea and Caldas, were engaged in the study of the *Chinchonæ* of New Granada, the former residing in South America, chiefly at Bogota, from 1783, until his death in 1808. They also spelt the word correctly. . . .'

"That Linnæus could not have been ignorant of the correct spelling at a much earlier date than that mentioned seems probable from the following circumstance:—In 1758, J. Ch. P. Petersen read at Upsala an academic dissertation, 'De Cortice Peruviano,' Linnæus presiding. In this production, which was afterwards printed, the name of the Spanish Viceroy appears (more than once) as 'Comes del Chinchon,' while the bark is spoken of as 'Chinchona,' and never as Cinchona ('quamvis nonnulli Chinchonam in scorbuto esse magni ponderis remedium . . . .' p. 10).

"As to Mutis, Mr. Markham overlooks the fact that that botanist was residing at Bogota, not merely in 1783, but in 1763, under which latter date he wrote thence to Linnæus; and that a correspondence was kept up between them for eighteen years. Some of Mutis's letters are fortunately extant, and form part of the Linnæan collections at Burlington House. As they throw some light on the subject, I have made from them a few extracts. Translations of the letters may be found in Sir J. E. Smith's 'Selection of the Correspondence of Linnæus,' London, 1821.

"24th Sept., 1764. (Mutis to Linnæus). 'Verum ne plane ineptissimæ hæ literæ tibi viderentur, iconem et flores quosdam Chinchonæ adjungere duxi. An descriptioni suæ figuram ullam addiderit Celeberrimus de la Condamine, vel an plantam siccam examinasse tibi licuerit, necne, cum nullam notam in descriptione Chinchonæ editionis Holmiæ 54 videam, non plane mihi constat.' [The drawing and specimens here alluded to, still exist in the Linnean herbarium.]

"3 Oct., 1767.—(The same to the same.) '. . . sane præter ultimas lineas, in quibus nunciabatur, te Cinchonam accepisse; quasque in Civitate Bogotensi, antequam illinc longissimæ peregrinationi paratus decederem, summa jucunditate legisse contigit. . .'

"15 May, 1770.—In this letter the name of the plant occurs four times, and is always written after the fashion of Linnæus with one *h*. Appended to the letter, Mutis sends a botanical description of a plant which he calls *Cinchona Gironensis.*

"6 June, 1773.—Mutis here acknowledges the receipt from Linnæus of certain works of the latter, and expresses his pleasure at the honourable mention of himself by Linnæus under the head of Cinchona; and he also refers to a small present which he transmits by Don Ruiz-Pavon, who is going to Upsala.

"8 Feb., 1777.—This letter contains notes on some plants sent by Mutis to Linnæus, one of them being entered as *Cinchona Bogotensis.*

"12 Sept., 1778.—A long letter of condolence from Mutis to the younger Linnæus. It contains the following passage:—'Maxime disto a solo natali Cinchonæ officinalis a me detectæ, cujus viciniis crescit etiam Mutisia.'

"In none of these letters is there a hint of disapprobation of the name Cinchona, which it will be noticed that Mutis adopts, immediately he finds it used by Linnæus.

"Mr. Markham asserts that the error was pointed out by Ruiz and Pavon. But surely he cannot be conversant with the 'Quinologia' of Ruiz, published at Madrid in 1792, or with the 'Suplemento,' which appeared, under the joint authorship of Ruiz and Pavon, nine years later, in neither of which works is the name of Linnæus's genus written otherwise than Cinchona. Mr. Markham must be also unaware that in the 'Flora Peruviana et Chilensis' of Ruiz and Pavon, the name in dispute is uniformly written Cinchona, and never Chinchona. Pavon, indeed in his later years is stated by Howard to have pleaded for the word Chinchona. This was done in his 'Nueva Quinologia,' a work written between 1821 and 1826, but which never saw the light until 1862, when it was edited in an abridged form by Mr. Howard.

"But the error in the name of the Spanish viceroy originated long before the time of Linnæus. Sebastiano Bado, the author of 'Anastasis Corticis Peruviæ' (Genoa, 1663), and one of the principal authorities for the early history of Peruvian bark, writes '*Cinchon*' for Chinchon. Morton, in his 'Pyretologia,' 1692, mentions the Count's name in the same inaccurate manner. So does La Condamine in 1738, and Geoffroy in 1741. By some of these writers Linnæus was misled, and was afterwards, perhaps, fortified in his error by the rules he had laid down about the immutability of generic names.

"That one of these rules was supposed to apply to the case in question, is evident from the remark of Ruiz,—'Linneo parece que debió haber expresado el titulo de los Condes de *Chinchon* en su género, dandole el nombre de *Chinchona* y no el de *Cinchona*, con el que tambien le nombro yo, atendiendo al Canon 243, de su Filosofía Botánica en que dice, *Nomen genericum dignum alio, licet aptiore, permutare non licet.*' *

"Though the Canons of Linnæus may no longer command the implicit obedience that they were once thought to deserve, it cannot be denied that there is a general reluctance among botanists to alter the Linnean names, and this is particularly the case in the present instance, where the alteration advocated would require to be followed in innumerable writings on pharmacy and chemistry. 'In our science,' wrote Dr. J. E. Smith, in 1807 ('Introduction to Botany'), 'the names established throughout the works of Linnæus are become current

"* It seems that Linnæus ought to have indicated the title of the Counts of Chinchon, by giving to his genus the name Chinchona, and not Cinchona, which latter, however, I adopt, in accordance with Canon 243 of the 'Philosophia Botanica,' which says *Nomen genericum*, etc."

coin, nor can they be altered without great inconvenience. Perhaps, if he had foreseen the future authority and popularity of his writings, he might himself have improved upon many which he adopted out of deference to his predecessors, and it is in some cases to be regretted that he has not sufficiently done so.' "

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The Annual Supper of this society was held on Wednesday evening, the 27th January, at the Maypole Hotel, Mr. Fitzhugh, President, in the chair; Mr. Lewis in the vice-chair.

After the usual loyal toasts, the Chairman proposed "The Pharmaceutical Society of Great Britain," and alluded to the improvements in the prospects and condition of pharmacy and its followers, educationally, since its establishment. Referring to the examinations, the speaker regretted the effect of so large a number of failures, both in the Preliminary and Minor examinations, as producing inconvenience to the trade throughout the country. He was of opinion, however, that the failures showed the necessity of examination and that the inconvenience must be cheerfully endured for the good to be hereafter derived. In coupling the name of Mr. Atherton, a member of the Council, with the toast, the Chairman thought they had cause to congratulate themselves that the chemists of Nottingham had a representative who had to such an extent their confidence and regard.

Mr. J. H. Atherton, in responding, stated that he feared in some parts of the provinces, the Pharmaceutical Society, its Examiners, and even the Council had incurred undeserved unpopularity on account of the extraordinary number of rejected candidates at the Preliminary and Minor examinations during the past year. He need not say how unjust such censure was. He believed the board of examiners to be composed of thoroughly honest and impartial men, who did their utmost to carry out their important duties without fear or favour. They must remember that last year was an exceptional one, the fear of a more stringent examination had no doubt been the cause of the great rush of candidates to try their luck (for with the majority he believed that was the proper expression) and with the result they knew so well. He had little doubt in his own mind that had candidates relied more on themselves and less on the fallacious system commonly called "cram," the proportion of failures would have been considerably diminished. What could be expected of young men who postponed all preparation for examination until the last moment, relying on the reputed success of certain professional teachers to impart the information in two months by means of condensed notes and ingenious aids to memory? Even supposing they passed the examination, the information was useless to them afterwards. The bearing of these failures on the trade at large was important, and was not so black as was generally thought. There would be for some time a difficulty in obtaining assistants; this would have to be met by the employment and training of unskilled labour; many of the operations of the laboratory and shop could be done by such persons after a little training. The speaker thought this would be an advantage, as in some country places assistants and apprentices were little better than porters. The reduction in the number of assistants and apprentices must cause, ultimately, a reduction in the number of chemists and druggists, and it did not require a very vivid imagination to foresee—what all desired to see,—better trade, better class of men, better prices, and so on, until pharmacy attained its proper educational and social condition. The failures in the Preliminary examination appeared to be the most serious, and the speaker thought a change was required in some way, for if the advent of apprentices was checked too much the trade would be very much inconvenienced. From personal observation, he was quite certain that the chief failures were amongst those who had allowed too long a period to elapse after leaving school,—a strong argument against binding apprentices before they have passed the examination. After calling the attention of the meeting to the provisions of the benevolent fund, Mr. Atherton concluded by making an appeal on behalf of the fund.

Mr. Williams, Hon. Sec., proposed the "Medical Profession," and alluded humorously to the increase of the patent medicine trade.

Mr. Atherton proposed "Success to the Nottingham and Notts Chemists' Association," and alluded to the want of activity most of the local associations exhibited, and urged upon those present the almost absolute necessity of such organizations. Pharmacy at the present time was in a transition state, and it behoved all interested in its progress to do something to help it onwards. At the present time it was the aim of local associations to provide efficient instruction for young men at as cheap rates as possible, and to do all in their power to encourage study and mutual improvement amongst them; but this was only a temporary condition, it was not certainly their intention to help to push men into the trade cheaply. The future of such societies was much more ambitious than their operation at the present time indicated. They must aim at providing thoroughly practical instruction by experienced pharmacists, and charge accordingly; there was no reason why a fee of two or three guineas the session should not be paid, and regular schools be established for certain districts; but he thought that the first step in that direction would be the requirement by the board of examiners of certificates of each candidate having attended some such course either in London or some recognized school in the provinces. In the meantime, they must individually do all in their power to encourage the managers of the association in their work. In connection with the toast, he would couple the name of the President of the Society, Mr. Fitzhugh, a man whom they all thoroughly esteemed, and with whom it was a pleasure to be associated.

Mr. Rayner proposed "The Teachers," and coupled with the toast the names of Mr. Major and Mr. Copley. Mr. Major having responded, Mr. Copley, in reply, said that in his experience the candidates for the Minor examination had not complained of the undue severity of the questions, and expressed a hope that the present standard would never be lowered, as he thought that those who were unable to pass the Minor examination as it is now conducted would be unfit for the proper conduct of the business.

Several other toasts were proposed and responded to. The proceedings were enlivened by songs and recitations, etc.

ANNUAL FESTIVAL OF THE GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The annual festive gathering of the members and friends of this society was held in the Crown Halls, Sauchiehall Street, on Wednesday, 3rd February. About 200 sat down to supper. Mr. John Currie, President, occupied the chair, and was supported by Drs. Miller and Milnes. Messrs. Greig, Kinninmont, Hamilton, McAdam, Fenwick, Fairlie (Secretary), McKenzie and ladies. Messrs. Whyte and Davison acted as croupiers, who were supported by Drs. McLean, Smith, and Moffatt, Messrs. Dun, Townshend, Scmitz and ladies. After supper the usual loyal and patriotic toasts were given from the chair, and duly responded to, Mr. Dun replying for the "Reserve Forces." The toast of the evening, "Success to the Association and Annual Festival," was proposed by Mr. Currie and replied to by the Secretary and Treasurer, Messrs. Fairlie and McKenzie. The toast of "The Ladies" was proposed by Dr. T. D. Moffatt, and replied to by Mr. John Foster. Among the other toasts on the programme were "The Medical Profession," "Chemical Science," etc.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 13, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE AMENDMENT OF THE ADULTERATION ACTS.

SHORTLY after this Journal goes to press, Mr. SCLATER BOOTH, the present head of the Local Government Board, will, pursuant to notice, ask leave to introduce a Bill to repeal the Adulteration of Food Acts, and make better provision for the sale of food and drugs in a pure state. It would be superfluous to insist upon the necessity for some amendment of the law in this respect, and we are glad to find that its urgency has not been overlooked. At present, of course, no information is obtainable as to the nature of the amendments proposed, but we shall take the earliest opportunity of placing our readers in possession of full particulars concerning them.

Meanwhile, it is worth mentioning that in several parts of the country the subject of the Adulteration Acts is attracting considerable attention, and steps are being taken by various associations with the view of suggesting alterations and improvements of the existing law. As an instance of such action we must specially mention a report by the Committee of the Birmingham and District Grocery Mutual Protection Association, containing a variety of suggestions adopted after carefully considering, with legal assistance, the operation of the Adulteration Acts. This report, which has been submitted to Mr. MUNTZ, is stated to have received his cordial assent; and, as it may therefore be expected this active participator in the legislation relating to adulteration will support the views put forward in this report, a statement of them will, we believe, be useful as well as interesting to our readers.

In the first place the report dwells upon the considerable injury that has been done to a number of respectable tradesmen, mainly in consequence of the want of knowledge on the part of analysts as to whether the presence of certain substances in various commodities constitutes an adulteration or not, and partly, also by the absence of any authoritative standards of purity in relation to imported and manufactured articles of food, drink, and drugs. As a remedy for this it is suggested that the Board of Trade should appoint analysts whose duty it should be to examine all such articles, with the object of establishing proper standards of purity, and if necessary varying them from time to time to meet the changing wants of consumers.

In reference to articles that are mixtures, it is suggested that it should be sufficient for the seller to state on the packets that the article is a mixture, and that it contains nothing injurious to health.

As regards the liability of the retail sellers of adulterated articles to the penalties of the Act, even when they did not know the articles were adulterated, but merely sold them as they had bought them, it is considered by the Birmingham Committee that great injustice has been inflicted upon honest traders by the proceedings under the second section of the Act. The Committee strenuously takes the ground that "no person should be held criminally responsible for "an act innocently done;" but at the same time it seems to be admitted that retail dealers are responsible for failing to certify themselves that the commodities they sell are pure and unadulterated, since it is suggested that the *onus probandi* should be put on the seller of adulterated goods, and that he should be held to be guilty *unless* he satisfied the Court that he did not know the articles sold by him were adulterated. On the other hand it is considered that the manufacturers of adulterated articles should in all cases be liable to penalty whether or not they personally knew of the adulteration.

Among other suggestions it is proposed that all Public Analysts should be paid by salary, and that it should be their duty to analyse any article brought to them, and certify the results for a certain fixed fee, to be paid to the fund from which the analyst's salary is derived. The appointment of special inspectors to carry out the provisions of the Act is recommended, and it is suggested that the inspector should leave with the seller of any article taken for analysis a sealed sample, so that the seller may, if he think fit, take it in that condition to an independent analyst; also, that a copy of the official analyst's certificate should be sent to the seller of any article examined by him, and that, in the event of prosecution, the analyst should attend in Court for examination on receiving notice to do so from the seller of the article impeached.

MEDICAL AND PHARMACEUTICAL EDUCATION AT A DISCOUNT.

THE state of Missouri has contributed its quota towards the solution of the education question, and it is by no means encouraging. It occurs in the report of a Committee appointed by the St. Louis Medical Society to consider the question of the mutual relations existing between physicians and druggists That Committee appears to have "resolved that thirty years' experience in elevating (*sic*) the standard "of medicine by the multiplication of schools and the "cheapening of diplomas has proved a signal failure," and that it is necessary to "discountenance and dis- "courage a similar suicidal and degrading system, "which is being inaugurated for pharmacy by un-

"scrupulous and ambitious aspirants, who, for the "sake of personal gain and notoriety, are willing to "sacrifice both their profession and their friends." Of course, after this evidence of its paternal regard for pharmacy it is not surprising to find that the Committee's anxiety extends to the instruction of pharmacists in their duties with respect to the conscientious dispensing of prescriptions, the renewing of prescriptions without the authority of the physician, the literary property of the physician in the prescription, and sundry similar matters. But we hardly expected to find it seriously proposed by any one outside a lunatic asylum, that laws should be enacted limiting the retail sale of poisons to the "filling of prescriptions duly and plainly signed by responsible practising physicians."

DRUGGISTS' STATISTICS IN THE UNITED STATES.

A writer in the *American Journal of Pharmacy* states that the number of druggists in the United States, according to the last census returns, is 17,369, of whom 33 are females, and 392 are 60 years of age or more. Only 14,273 are natives of the United States; whilst no less than 1470, or more than 8 per cent. of the whole are Germans. England and Wales have sent the next largest contribution—namely, 607; then Ireland, 339; British America, 189; France, 118; Scotland, 64; China and Japan, 51; Italy, 7; other countries, 163. Compared with the returns for 1850, druggists have increased in the United States in a ratio considerably beyond that of the increase in the population; for in the former year they were only 1 to 3778 of the population, but in 1870 they were 1 to 2219. During the same time the proportion of patent medicine manufacturers has increased from 59, or 1 to 369,472 of the population to 409, or 1 to 94,274.

THE ARTICHOKE A REMEDY FOR RHEUMATISM.

In the *British Medical Journal* for December 19, Dr. Copeland, of Norwich, has published some cases confirmatory of a former paper recommending the treatment of rheumatism with the common artichoke in the form either of tincture or extract. These are prepared from the leaves gathered just before the vegetable is fit for food, and whilst they are full of juice. If the leaves are left until the top is cut off for cooking purposes and the plant begins to wither, the product is useless and inert. To this circumstance, Dr. Copeland attributes the negative results met with by some practitioners who have tried this medicine.

THE IRISH PHARMACY BILL.

In accordance with notice given, Mr. Errington was on Thursday night to ask the Chief Secretary for Ireland, whether, in compliance with the recommendations of the Select Committee on the Apothecaries' Licences Bill of last session, it is his intention to introduce this session a Bill for the establishment of a Pharmaceutical Society in Ireland.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The seventh General Meeting was held at the Royal Institution, January 28th, 1875. The President, Mr. A. H. Mason, F.C.S., in the chair. Donations to the library of the *Pharmaceutical Journal* and the *American Chemist* were received and duly acknowledged. There being no miscellaneous communications, the President called on Mr. E. Davies, F.C.S., to read a paper on—

Nitrate of Soda, Its Production and Uses.

Nitrate of soda is a substance of so much commercial importance, that although its use in pharmacy is limited to the preparation of arsenate of soda, no excuse is necessary for bringing it under the notice of a Chemists' Association. A remarkable fact connected with this substance is that only on a narrow tract of the earth's surface are the conditions for its production found. In South America on the western side of the Andes is a desert region extending from near Arica for about 500 miles south. Near the sea the land rises abruptly to a height of from 2000 to 3000 feet, where a table land stretches to the foot of the Cordilleras. At first, on the side of the sea, the surface of the land is uneven, but nearer the mountains becomes a level plain, 30 miles wide. This is the pampa of Tamarugal. The nitrate district lies in the uneven part of the table land,—in Peru, about 10 miles from the coast to the edge of the pampa of Tamarugal—and stretches from Pisagua, 45 miles north of Iquique to Patillos, 30 miles south. In Bolivia there is a district not yet much worked.

The deposit is not continuous but is found principally on the edges of depression which have once been lagoons. It is covered by a layer of indurated gravel called "costra," on an average about 50 inches thick, the nitrate of soda layers averaging 25 inches in thickness. The layer is sometimes four yards thick. . The raw material called "caliche" is of two kinds, one light coloured and solid, the other softer and darker in colour.

The mining is done by blasting away the "costra" with gunpowder, made in the country from nitrate of soda. The "caliche" is broken up before lixiviation into small pieces, and dissolved either in open iron tanks or in closed vertical cylinders. In either case steam is led into the bottom separated from the charge by a false bottom of perforated iron plates. Water or the mother liquor of a previous operation is put on the broken "caliche," steam injected, and the solution drawn off and allowed to settle; when clear it is put into the crystallizers. The crystals are drained and dried, and the mother liquor used again. The great difficulties are the scarcity of water and fuel. Water must be obtained from deep wells, 200 to 300 feet in depth. It is very brackish and unfit for human consumption, though the mules drink it. Coal is brought from Iquique, and costs about thirty dollars per ton at the works.

An attempt is being made to bring down a solution made with cold water, in iron pipes to Iquique, in order to evaporate it there in closed cylinders, and condense the steam to furnish water for the use of the town, but it is not yet completely successful.

The origin of these deposits is not certainly known. There is no rain in these districts owing to the prevailing wind, the south-east trade wind, being deprived of its moisture in ascending the long eastern slope of the Andes, and then becoming warmer as it descends it tends rather to take up than to deposit moisture. The table land has evidently been at one time a marshy plain at the level of the sea, with extensive salt-water lagoons. Mr. D. Forbes, in a long article on the Geology of Peru and Bolivia (*Geological Magazine*, 1861), gives as an explanation of the deposits, that on evaporation, chloride of sodium decomposed carbonate of lime, forming chloride of calcium and carbonate of soda. The alkaline carbonate in presence of decomposing nitrogenous matter then gave rise to nitrate of soda. I cannot think that this is correct, for on evaporating chloride of sodium with precipitated calcium carbonate, I found that the residue, when moistened with water, was not even alkaline to test paper. When the dried mixture was treated with alcohol, it appeared that a slight decomposition had taken place, the alcohol containing a little chloride of calcium, and the residue being decidedly alkaline. The reaction may, therefore, under some conditions, give an alkaline carbonate, but it seems more probable to me to find a source for the alkaline carbonate in the vegetation which would be found on the salt-encrusted land. Such plants contain large quantities of organic soda salts, and on decaying would furnish both soda and nitrogen. The land has been subsequently upheaved. The deposit is comparatively modern, being found in post-Tertiary strata.

Uses.—The two principal uses are in the sulphuric acid manufacture, and as manure. No other means of carrying the oxygen of the atmosphere to the sulphurous acid has proved practically successful when sulphuric acid is to be made. In making sulphate of soda, Hargreave's process may, perhaps, help us to dispense with it. As manure, it is an alternative source of nitrogen with sulphate of ammonia. The matter of price has some influence on the choice of these two materials, but sulphate of ammonia is preferred as being more certainly returned as ammonia in any analysis which may be made. As manure it appears to be quite equal to an equivalent quantity of sulphate of ammonia.

In making nitric acid, nitrate of soda has the advantages that it is cheaper than saltpetre and gives more nitric acid, weight for weight, and also the residual product is directly available in alkali manufacture. It is not so readily purified from chlorides as nitrate of potash is, so the latter is used when a pure acid is required.

In the manufacture of saltpetre a valuable application of nitrate of soda has been found. The deposits at Stassfurt have given abundant supplies of chloride of potassium, which when mixed in saturated hot solution with a strong solution of nitrate of soda yield crystals of nitrate of potash on cooling.

Gunpowder has been made from nitrate of soda, but its tendency to become damp renders it insuitable. Probably, if quite free from chlorides, this would be less marked.

Other minor uses have been found for it, as in Heaton's process for purifying cast iron from sulphur and phosphorus; making oxygen by heating it with oxide of zinc, and the manufacture of manganates; but these are not important at present.

Several years since, when engaged in a chemical works some nitre drainings were sent for use. I found so much iodine in it that I made inquiries about the supply, but finding that there was very little to be had, I did not prosecute the research. The mother liquors of the nitrate of soda contain ·28 to ·36 per cent. of iodine. This is now successfully extracted. It was at first sent over as cuprous iodide, which is precipitated when sulphate of copper and protosulphate of iron are added to the solution of an iodide. This contains about 60 per cent. of iodine. Now the iodine is obtained in Peru, and sent over in a very pure state, some samples containing 99 per cent.

In conclusion, I have to own my great obligations to a paper by Mr. Flagg, in the *American Chemist*, for many of the facts connected with the extraction of the nitrate and the nitre districts.

A discussion followed in which Mr. Belcher, a gentleman connected with the firm which imports the principal part of Peruvian iodine, stated that the processes for extracting the iodine in Peru were kept secret as much as possible; and also that there was a great loss from evaporation in bringing it over.

Mr. Armstrong suggested that the use of casks lined with paraffin might prevent the evaporation. He expected that with a lower price, many important uses would be found for iodine.

Other members took part in the discussion, and the proceedings terminated with a vote of thanks to Mr. Davies.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Friday evening January 29, a supper was given in connection with the above Society, at the Wickliffe Rooms, Leicester. The chair was taken at 8.45 by Mr. H. Nettleship, and the vice-chair by Mr. E. H. Butler.

After supper, the usual loyal toasts having been drunk, Mr. J. Young proposed the Pharmaceutical Society of Great Britain. In doing so, Mr. Young alluded to the work accomplished by the Society in the past, and said that, though there might be various opinions as to imperfections existing in its constitution, there could be no doubt that it had been instrumental in raising the status of the trade, and in improving the quality of the drugs and chemicals supplied to the public.

Mr. W. B. Clark briefly responded, showing that in some degree, at least, the local Association should be to the town what the Pharmaceutical Society is to the country.

At the request of the chairman, Mr. E. J. Bishop then rose to propose the toast of the evening, "Success to the Leicester Chemists' Assistants and Apprentices' Association," saying, that no words of his were needed to recommend the toast to the favourable notice of all present, as most of them had been, either directly or indirectly, benefitted by the existence of the Society. He alluded feelingly to his own long connection with it, and expressed his belief that, being founded on right principles, and for the accomplishment of a very worthy object, it would still continue to be the guide and help of students preparing for the examinations.

Mr. E. H. Butler, in responding, referred to the work which had been done during the past year, with a view of showing that the object for which the Association was established—viz., helping young men to prepare for the Pharmaceutical examinations—had been effected; and urged all the assistants and apprentices before him to reap the full benefit of the advantages offered by the Society, assuring them that a regular attendance at its classes and lectures would considerably lessen the difficulties they would have to encounter.

Various other toasts were proposed and responded to, as "The Town and Trade of Leicester," "The Principals," "The Committee and Class Teachers," and "The Ladies."

The proceedings of the evening were enlivened by several songs, excellently rendered by Messrs. Baker and Green, and were closed by the company drinking to "The Health of the Chairman and Vice-Chairman," with musical honours.

ASSOCIATION OF CHEMISTS AND DRUGGISTS FOR WOLVERHAMPTON AND DISTRICT.

The members and associates of the above Society held a meeting in the Committee Room of the Agricultural Hall on Wednesday evening, February 3rd, under the presidency of Mr. R. H. Lowe. The table was covered with books, scientific apparatus, and valuable specimens of rare drugs, which had been presented by various friends in all parts of the kingdom. A large and well furnished cabinet of materia medica specimens, kindly given by Messrs. Evans, Lescher and Evans, was much admired.

After the minutes of the last meeting had been read and confirmed, and the amended rules of the Association passed, Mr. Brevitt (one of the Honorary Secretaries) read the report of the Sub-Committee, by which it would appear that, although the Association has been in existence not quite two months, nearly eighty members and associates had already joined. The Committee felt sure, as the prosperity of the Society increased, its circle of usefulness would be enlarged, and that chemists in other towns, not in the immediate neighbourhood of Wolverhampton would join. Regret was expressed that assistants and apprentices, for whose good the Association had been formed, did not more cordially take the matter up. The classes on materia medica and botany were well attended, and the lecturer (Mr. Stokes Dewson) had already made himself highly popular with the students. Many gentlemen having at heart the welfare of provincial pharmacy had, as soon as the establishment of the Association was known, kindly offered assistance and advice. Professor Attfield (of the Pharmaceutical Society) had sent the following letter of advice to the students—advice which ought to be written in letters of gold—in which he says—

"I wish your Association every success. You rightly say that I take deep interest in the progress of pharmaceutical education. I cordially sympathise with every association, school, or other organization having for its object the promotion of real pharmaceutical education. Consistently with that interest and sympathy I denounce mere preparation for examination. The two are perfectly distinct because examination at its best, and in the nature of things, is an inefficient test of education. Only when conjoined with and restricted to the subjects of a well-defined curriculum of study, does examination become a trustworthy test of education. I am sure that the members of your Association will range themselves on the side of real education, and that your young men will recognize examination not as an end in itself to be prepared for, but as a test of the soundness with which they have slowly and steadily, by years of honest endeavours, prepared themselves for the business of their life.

"Yours faithfully, JOHN ATTFIELD."

The following valuable donations had also been received:—Professor Attfield, Ph.D., F.C.S., etc., 'Chemistry: General, Medical, and Pharmaceutical;' Professor Bentley, F.L.S., etc., 'Manual of Botany;' Professor Proctor, 'Practical Pharmacy;' Dr. John Muter, F.C.S., etc., 'Pharmaceutical Chemistry' and 'Materia Medica;' Dr. Frankland (per the borough analyst), 'Organic and Inorganic Chemistry,' 2 vols.; Mr. Frank Lescher, 'Elements of Pharmacy;' Messrs. Evans, Son, and Lescher, a cabinet of Materia Medica; Messrs. Southall and Barclay, a cabinet of Materia Medica; Mr. J. B. Smith, 'Pharmaceutical Guide;' Mr. Daniel Hanbury, 'Pharmacographia;' Mr. A. Sadgrove, 'Chart of Materia Medica;' Mr. A. W. Gerrard, a very fine specimen of Jaborandi; Mr. W. Y. Brevitt, Southall's 'Materia Medica;' Mr. F. J. Barrett, F.C.S., mounted specimens of plants; and various other donations. The British Pharmaceutical Conference had forwarded (by their secretaries) a letter of recognition, and had promised to forward the Year-Books as they were published. The Secretaries had hoped to receive some assistance from the Pharmaceutical Society, the "Alma Mater" of most pharmaceutists, in founding a provincial school of pharmacy in Wolverhampton. In answer to the application of the Presidents, a long list of questions had been received which the Secretaries could not have answered satisfactorily on account of the recent establishment of the Association, and a request that the balance-sheet of the previous year might be forwarded. A request for the Journal of the Society appeared to be disregarded.* However,—as a member present remarked—self-help was best, and now it mattered but little whether the Association were recognized by the Pharmaceutical Society or not. In the autumn it is proposed to commence classes on pharmaceutical chemistry, pharmacy, and materia medica, in addition to the lectures now being given.

Two auditors (Mr. Hamp, Penn Road, and Mr. Theophilus Wedge, Victoria Street) were then elected for the present year. Three assistants (chosen by the associates)—Messrs. Cooley, Whewell, and Matthews—were elected as members of the Council. Mr. E. W. T. Jones, F.C.S. (the borough analyst) was then proposed, seconded, and elected by acclamation, an honorary and corresponding member.

A letter from Mr. Wentworth Lascelles Scott, F.C.S. (analyst for North Staffordshire, etc.) was then read by Mr. G. A. Davenport, expressing sympathy with the objects of the Society, and offering to deliver one or more lectures on various subjects during the session. This offer was most thankfully accepted, and the Secretaries were requested to make the necessary arrangements.

Mr. Stokes Dewson (of the Queen's Hospital) then read a highly interesting account of the two new drugs "Jaborandi and Boldo." After speaking of the botanical and geographical origin of these plants, and describing their structure and peculiarities and the different forms in which they occurred in commerce, their physiological action was fully commented on. The action of jaborandi as a sialagogue and diaphoretic was spoken of as remarkable, and Mr. Martindale's experiments upon himself were quoted. The tonic properties of boldo, supposed to be a valuable remedy in liver complaints, were also referred to. Various specimens of each of these drugs were exhibited.

After a very cordial vote of thanks to the author;—

Mr. F. J. Barrett, F.C.S. (the Hospital Pharmaceutist) gave an interesting account of "Milk Analysis," explaining the several processes by means of Horsley's lactometer. He spoke of the various constituents of milk, butter, oil, casein, sugar, and salts, principally phosphates of lime and magnesia, and explained how they contributed as a food to the formation of skin, cellular tissue, muscle, and bone. After commenting on the microscopical appearance of milk, and giving a short account of the way in which butter and cheese were produced, he showed by means of a graduated tube the separated constituents of milk, and pointed out how readily adulterations might be detected by means of Mr. Horsley's very ingenious apparatus. The adulteration of butter was next alluded to; samples of pure and sophisticated butter were shown, and the mode of detecting such adulterants demonstrated.

A short discussion then took place, in which Mr. Jones, F.C.S., took part; and after Mr. Barrett had replied, a vote of thanks was unanimously passed.

A very ingenious and portable oil lamp for microscopic work was then shown and explained by Mr. Jones.

A general discussion, on various subjects of pharmaceutical interest, followed by a vote of thanks to the Chairman, concluded a most enjoyable evening.

The next meeting is arranged to take place early in March, for which several interesting papers have been promised.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

ASSISTANTS' SECTION.

The fifth meeting of session 1874-75 was held in the West Hall, Anderson's University, on Wednesday, 27th January, at 9 p.m. The President, Mr. John C. Hunter, occupied the chair. The minutes of the last meeting having been adopted, the Chairman called upon the Vice-President, Mr. James Johnston Weir, to read a paper on "The Laughing Animal." Mr. Weir informed the meeting that man was the laughing animal, after which he described the differences which exist between the face of man and that of the lower animals. Mr. Weir carefully went over the nerves, which produce laughter, and referred to a few of the causes of laughter.

At the close of the paper, several questions were put by a few of the members on certain points in which they differed, and a short discussion followed in which the Chairman, Messrs. Nance, M'Cann, Taylor, and Foster took part; after which the Chairman proposed a vote of thanks to Mr. Weir for his very interesting and instructive paper, which was cordially responded to. Several new members were then elected.

The Secretary announced that the next meeting would be held on the 24th February, when Mr. M'Cann would read a paper on "Geology."

* The grievance of the sub-committee of the Wolverhampton Association seems to be, that it has been required to make an application on the form framed by the Council for the purpose of eliciting full information before making a grant. —ED. PH. J.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 4th of February, 1875. Professor Odling, F.R.S., etc., in the chair. The minutes of the previous meeting having been read there was a communication from Mr. G. Whewell, entitled "Test for Carbolic Acid." A note "On the Action of Anhydrous Ether on Titanic Tetrachloride," by Mr. P. P. Benson, was then read. Two crystalline compounds are obtained in this reaction, the one boiling at 105°-120° C., and melting at 42°-45° C. has the composition $TiCl_4(C_4H_{10})O$; the other, *titanium ethyl trichlorhydrine*, $TiCl_3(C_2H_5O)$ melts at 76°-78° C., and boils at 186°-188°. The last paper was by Mr. W. H. Perkin, F.R.S., "On Dibromacetic and Glyoxylic Acids." An animated discussion ensued, and the meeting finally adjourned until Thursday, 18th of February, when there will be a lecture, by Professor Clerk Maxwell, "On the Dynamical Evidence of the Molecular Constitution of Bodies." The Faraday lecture will be delivered by Dr. A. W. Hofmann, on the 18th of March.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture III.

The Influence of Common or Ethylic Alcohol on Animal Life. The Primary Physiological Action of Alcohol.

I have to consider next the primary action of ethylic alcohol on animal life. This is the alcoholic spirit which enters into wines, beers, and ordinary spirituous liquors.

There are two modes in which this subject must be discussed. One relates to the mere physical action of alcohol upon the body, the other to its action as a food for the body. Of the varied substances which we take into our systems, some, like chloroform or opium, produce very marked physical effects, which we may call physiological, but which have nothing to do with the nourishment of the organism, nor with the sustainment of its vital power. Other substances act as foods, producing certain continuous phenomena of structural build and of vital function. Alcohol is peculiar in that we are obliged to consider it, at the present time, from each of these points of view, and to-night I take up the first, I mean the purely physical action of alcohol, reserving the question of its qualities as a food for a future lecture.

A very simple problem lies before us. The sum of £117,000,000 of money is invested in this country on alcohol as a commercial substance. Where does the alcohol go? We know that the larger part of it goes for consumption by human beings. A little—I mean by comparison a little—is used for the purposes of art and science; but the greater portion of it, practically all but the whole of it, is consumed by human beings. Thus a question arises, we may almost say, of engineering and commerce, a question, therefore, particularly worthy of this Society, viz., What is the good of this invested capital, and of the substance which it supplies? It is not necessary for any of us to consider ourselves as physicians in studying this matter, but we may all consider ourselves as animal engineers, anxious to know the physical properties of agents which influence the animal life. To put it in a very practical way, suppose that there was no question involved in regard to the influence of alcohol upon the body, but that in the course of the invention of motive engines—common inanimate engines, which can be made to produce motive power by the application of heat to water—it had originally become the practice from some circumstance to put into the engines so much spirit with the water, and to work the engines with this mixture. Then suppose somebody said, "This is a very expensive process of working the engines; maybe they will work as well without the spirit." You would then naturally inquire, "Can such be the fact?" And you would seek an engineer to fill the place I now have the honour to occupy, to explain to you the mechanism of the engines. You would also beg him to explain and put before you facts which would bear upon the point, whether the admixture of spirit and water was useful or useless? Now, please, consider me to-night as an engineer, and the animal body as the engine I am to speak upon. I am not going to address a word to you as a physician; I am not going to offer advice. I simply mean to place before you, as far as I know them, the facts relating to the physical effects of this thing alcohol, when it is put into one of those millions of engines which we call men.

Alcohol will enter the body—the engine of which I am about to speak—by many channels. It can be introduced by injecting it under the skin or into a vein. Exalted by heat into the form of vapour, it may be inhaled by man or animal, when it will penetrate into the lungs, will diffuse through the bronchial tubes, will pass into the minute air vesicles will travel through the minute circulation with the blood that is going to the heart, will condense in that blood, will go direct to the left side of the heart, thence into the arterial canals, and will be carried throughout the body. Or, again, the spirit can be taken in by the more ordinary channel, the stomach. Through this channel it finds its way, by two routes, into the circulation. A certain portion of it—the greater portion of it—is absorbed directly by the veins of the alimentary surface, finds its way straight into the larger veins, which lead up to the heart, and so onwards with the course of the blood. Another portion is picked up by those small structures which proceed from the mucous surface below the stomach, which are called *villi*, and from which originate a series of fine tubes that reach at last the lower portion of a common tube known as the thoracic duct. This ascending tube, lying in front of the spinal column, terminates at the junction of two large veins on the left side of the body, at a point where the venous blood, returning from the left arm, joins with the returning blood from the left side of the head on its way to the heart.

Thus in whatever way the alcohol is introduced it enters the blood; the shortest way is that by inhalation, the longest and most ordinary way is by the stomach. Indeed, except for experimental purposes, the introduction is always by this latter and longest route, and we may, for our practical purposes, only think of alcohol as a fluid taken by the mouth into the stomach, and absorbed like a food or a drink from the surface of the alimentary canal.

Suppose then a certain measure of alcohol is taken into the stomach, it will be absorbed there; but, previous to absorption, it will have to undergo a proper degree of dilution with water, for there is this peculiarity respecting alcohol when it is separated by an animal membrane from a watery fluid like the blood, that it will not pass through the membrane until it has become charged, to a given point of dilution, with water. It is itself, in fact, so greedy for water, it will pick it up from watery textures, and deprive them of it until, by its saturation, its power of reception is exhausted, after which it will diffuse into the current of circulating fluid.

To illustrate this fact of dilution, I introduce a simple experiment. Here is a bladder, in which has been placed a mixture consisting of equal parts of alcohol and distilled water. Into the neck of the bladder a long glass tube is inserted and firmly tied. Then the bladder is immersed in a saline fluid representing an artificial serum of blood. The result is that the alcohol in the bladder has absorbed water from the surrounding saline solution, and thereby a

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

column of fluid has passed up into the glass tube. A second mixture of alcohol and water, in the proportion, this time, of one part of alcohol to two of water, has been put into another bladder immersed in like manner in an artificial serum. In this instance, a little fluid has also passed from the outside into the bladder, so that there is a rise of water in the tube, but less than in the previous instance. A third mixture, consisting of one part of alcohol with three parts of water, is placed in another little bladder, and is also suspended in the artificial serum. In this case there was for a time a small rise of fluid in the tube connected with the bladder; but after a time, owing to the dilution which took place, a current from within outwards set in, and the tube became empty. Thus each bladder charged originally with the same quantity of fluid contains now a different quantity. The first contains more than it did originally; the second a little more; the third a little less. From the third absorption is taking place, and if I keep changing and replacing the outer fluid which surrounds the bladder with fresh serum, I could in time, owing to the double current of water into the bladder through its coats, and of water and alcohol out of the bladder into the serum, remove all the alcohol. In this way it is removed from the stomach into the circulating blood when it has been swallowed. When we dilute alcohol with water before drinking it we quicken its absorption. If we do not dilute it sufficiently it is diluted in the stomach by transudation of water in the stomach until the required reduction for its absorption; the current then sets in towards the blood, and passes into the circulating canals by the veins.

If you direct your attention to a diagram showing the circulation, you will see that all the returning veins end in the large trunks which terminate in the central organ of the circulation—the heart. The heart, a moving muscular organ, has four cavities; two above called the auricles, two below called the ventricles. The cavities on the right side are called respectively the right auricle and right ventricle; the cavities on the left side are called respectively the left auricle and the left ventricle. The right auricle receives all the venous blood of the body, and transmits it to the right ventricle; the right ventricle drives the blood over the lungs where the blood is arterialised; the left auricle receives the blood from the lungs, and transmits it to the left ventricle, which drives it through these arterial tubes over the whole of the body, whence it returns again by the veins to the right side of the heart, and so on, in circulation. Alcohol, therefore, entering the veins, makes its way in the course I have described through the right heart, through the lungs, through the left heart, through the body at large by the arteries. This is the course of its travel in the organism; what does it do as it makes the round?

As it passes through the circulation of the lungs it is exposed to the air, and some little of it, raised into vapour by the natural heat, is thrown off in expiration. If the quantity of it be large this loss may be considerable, and the odour of the spirit may be detected in the expired breath. If the quantity be small the loss will be comparatively little, as the spirit will be held in solution by the water in the blood. After it has passed through the lungs, and has been driven by the left heart over the arterial circuit, it passes into what is called the minute circulation, or the structural circulation of the organism. The arteries extend into very small vessels, which are called arterioles, and from these infinitely small vessels spring the equally minute radicals or roots of the veins which are ultimately to become the great rivers bearing the blood back to the heart. In its passage through this minute circulation the alcohol finds its way to every organ. To this brain, to these muscles, to these secreting or excreting organs, nay even into this bony structure itself, it moves with the blood. In some of these parts which are not excreting, it remains for a time diffused, and in those parts where there is a large per-centage of water it remains longer than in other parts. From some organs which have an open tube for conveying fluids away, as the liver and kidneys, it is thrown out or eliminated, and in this way a portion of it is ultimately removed from the body. The rest, passing round and round with the circulation, is probably decomposed and carried off in new forms of matter; but concerning this, more on a future occasion.

When we know the course which the alcohol takes in its passage through the body, from the period of its absorption to that of its elimination, we are the better able to judge what physical changes it induces in the different organs and structures with which it comes in contact. It first reaches the blood, but, as a rule, the quantity of it that enters is insufficient to produce any material effect in that fluid. If, however, the dose taken be poisonous or semi poisonous, then even the blood, rich as it is in water—and it contains seven hundred and ninety parts in a thousand—is affected. The alcohol is diffused through this water, and there it comes in contact with the other constituent parts, with the fibrine, that plastic substance which, when blood is drawn, clots and coagulates, and which is present in the proportion of from two to three parts in a thousand; with the albumen which exists in the proportion of seventy parts; with the salts which yield about ten parts; with the fatty matters; and lastly, with those minute, round bodies which float in myriads in the blood, which were discovered by the Dutch philosopher, Leeuwenhoek, as one of the first results of microscopical observation, about the middle of the seventeenth century, and which are called the blood globules or corpuscles. These little bodies are, in fact, cells; their discs, when natural, have a smooth outline; they are depressed in the centre, as I indicate on the board, and they are red in colour; the colour of the blood is, indeed, derived from them. We have discovered in recent years that there exist other corpuscles or cells in the blood in much smaller quantity, which are called white cells. Here is a drawing, showing very beautifully how these different cells float in the blood-stream within the vessels. The red corpuscles, you will observe, take the centre of the stream; the white lie externally near the sides of the vessels, moving less quickly. Our business is mainly with the red corpuscles. They perform the most important functions in the economy; they absorb, in great part, the oxygen which we inhale in breathing, and carry it to the extreme tissues of the body; they absorb, in great part, the carbonic acid gas which is produced in the combustion of the body in the extreme tissues, and bring that gas back to the lungs to be exchanged for oxygen there; in short, they are the vital instruments of the circulation.

With all these parts of the blood, with the water, fibrine, albumen, salts, fatty matter, and corpuscles, the alcohol comes in contact when it enters the blood, and, if it be in sufficient quantity, it produces disturbing action. I have watched this disturbance very carefully on the blood corpuscles, for in some animals we can see these floating along during life, and we can also observe them from men who are under alcohol by removing a speck of blood, and examining it with the microscope. The action of the alcohol, when it is observable, is varied. It may cause the corpuscles to run too closely together, and to adhere in rolls; it may modify their outline, making the clearly-defined smooth outer edge irregular or crenate, or even star-like, as I define it on the board; it may change the round corpuscle into the oval form, thus; or in very extreme cases it may produce what I may call a truncated form of corpuscle, in which the change is so great that if we did not trace it through all its stages we should be puzzled to know whether the object looked at were indeed a blood-cell. All these changes are due to the action of the spirit upon the water contained in the corpuscles; upon the capacity of the spirit to extract water from them. During every stage of modification of corpuscle thus described, the function to absorb and fix gases is impaired, and when the aggregation of the cells in masses is great, other difficulties arise, for the cells united together pass less easily than they should through the minute vessels of the lungs and of the general circulation, and impede the current, by which local injury is produced.

A further action upon the blood instituted by alcohol in excess, is upon the fibrine or the plastic colloidal matter. On this the spirit may act in two different ways, according to the degree in which it affects the water that holds the fibrine in solution. It may fix the water with the fibrine, and thus destroy the power of coagulation; or it may extract the water so determinately as to produce coagulation. These facts bear on a new and refined subject of research with which I must not trouble you further, except to add that the inquiry explains why in acute cases of poisoning by alcohol the blood is sometimes found quite fluid, at other times firmly coagulated in the vessels.

These are the only points I have time to touch upon in respect to the physical action of alcohol upon blood. I must pass next to blood vessels, and trace out the action upon those fine ramifications of the larger vessels which we call the minute circulation. Upon these parts the spirit exerts a singular influence, from which arises a series of phenomena, characteristic of action when even a moderate quantity of spirit is taken into the body. That we may follow out this position clearly, it is essential I should for a few minutes put alcohol out of sight altogether and describe the mechanism and governance of this minute circulating system.

(*To be continued.*)

Parliamentary and Law Proceedings.

Alleged Adulteration of Precipitated Sulphur in Leeds.

On Wednesday, February 10, Mr. Joseph Harrison, chemist, Town Street, Stanningley, was summoned before Mr. Bruce, sitting at the Borough Court, Leeds, for having unlawfully sold as unadulterated 4oz. of precipitated sulphur which was adulterated with sulphate of lime.

The Town Clerk said the object of laying the information was that the public might be thoroughly aware for the future what different things were supplied under different names; and that when they asked for one thing the tradesman was not justified in serving them with another. It was quite clear, according to the Pharmacopœia, that sulphur præcipitatum was the only form of milk of sulphur known to the medical profession, and the result of the process detailed in the Pharmacopœia was pure sulphur. But they were made aware that there was a preparation of milk of sulphur known in the trade, but which was not recognized in the Pharmacopœia. This milk of sulphur was made in a cheaper manner by the use of sulphuric acid, and as in this case the chemist was asked for precipitated sulphur, he was not justified in selling milk of sulphur, which was not pure sulphur. The statute threw upon Mr. Harrison, who was a registered chemist under the Act, the onus of knowing that that which he sold as precipitated sulphur contained 64 per cent. of sulphate of lime. It was important that this should be known, because this impure sulphur was prejudicial, inasmuch as when precipitated sulphur was ordered by a medical man to be taken, and instead of that, this milk of sulphur, as prepared with sulphuric acid, was administered, the beneficial result expected was not attained. If there was any prejudice in the public mind that this milk of sulphur was better than precipitated sulphur, it was unfortunate that such a feeling should prevail; but he was there to protect the public to this extent, that when they asked for precipitated sulphur, they were entitled to get pure sulphur, and if supplied with milk of sulphur, which was composed of a great quantity of lime, they did not get that which they asked for.

James Handford said that on the 2nd February he went to Mr. Harrison's shop and asked for a quarter of a pound of precipitated sulphur. The defendant's shopman gave it to him, and he paid 3*d*. for it. He told the shopman that he had bought it for the purpose of having it analysed, and said he could go with him and see it analysed. The shopman then called the defendant, and Mr. Harrison came to him. Witness told him the same thing, and the defendant replied, "I sell it just as I get it from the wholesale dealers, Messrs. Goodall and Backhouse, and I have not adulterated it myself, and I should be surprised if it were adulterated."

The Clerk read the report by Mr. Fairley, the borough analyst, which stated that the precipitated sulphur referred to was largely adulterated, containing not less than 64 per cent. of sulphate of lime.

Mr. Harrison said that the borough analyst and the Court had not yet recognized as a fact, what was nevertheless true, that there are two precipitated sulphurs in commercial circles—one of the new style and the other of the old style. He trusted that the analyst himself would admit this fact—that adulteration meant the act of corruption by an admixture with a foreign article. In that case he was sure the borough analyst would not assert that there had been an admixture here by defendant or by the parties from whom he bought it; and it was only fair to Messrs. Goodall, Backhouse and Co. to say that he was supplied with the precise article he wanted. He asked for precipitated sulphur. They asked, "Which? Do you mean the precipitated sulphur of the British Pharmacopœia of 1867, or what is ordinarily known in commercial circles as lac sulphuris?" He replied that he meant "lac sulphuris—milk of sulphur"—and it had always been supplied to him. He wished to point out that under the old style precipitated sulphur, milk of brimstone, milk of sulphur, and lac sulphuris were synonymous terms and applied to the same article; but the preparation of the British Pharmacopœia of 1867 was another thing. The article which he had supplied, and had supplied for thirty years, and the correctness of which had never been questioned, had been supplied by him and obtained by him as precipitated sulphur of the old style. It was unfortunate that in his business an article was known by many different names, and people would come and ask for the same thing under different names. In no case had he been asked for precipitated sulphur of the British Pharmacopœia. Precipitated sulphur of the British Pharmacopœia was an article which would not obtain among his customers, and they would either bring it back or make statements behind his back which would be injurious to him. He quoted from Rennie's "Supplement to the Pharmacopœia" (1837), and from Hooper's "Medical Dictionary" (1838), to show what was meant by sulphur præcipitatum at that time, and went on to say that it was only when the British Pharmacopœia was issued in 1867 that precipitated sulphur was recognized as distinct from lac sulphuris.

Mr. Bruce said the authorities quoted seemed to show that in 1837 those doctors treated lac sulphuris and sulphur præcipitatum as the same thing.

The Town Clerk said he did not think they need take the point further as to the state of things then. But could Mr. Harrison show that it was not in consequence of the injury resulting from sulphur not being properly made that in the last Pharmacopœia it was set out how it should be made in order to be pure sulphur.

Mr. Harrison said chemists and druggists were obliged to sell numerous articles which were not recognized in the British Pharmacopœia. What he wished to show was that there was another sulphur præcipitatum of the new style, which was quite distinct and different from the precipitated sulphur which is known in the market, and of which a hundred times more is sold, and will continue to be sold, than of the sulphur præcipitatum of the British Pharmacopœia, because the latter is not so nice to look at, it is more bitter, and it has a worse smell. He kept the precipitated sulphur of the new style, but he did not supply it unless it was asked for. He could not admit that this action was for the purpose of serving the public. The public wanted the article he had supplied to them, and they would have it.

Mr. Bruce said he could not convict at present without giving the defendant an opportunity of calling witnesses.

The Town Clerk said his *primâ facie* case was at present unanswered.

The case was adjourned till Tuesday next.

Mr. George Teasdale, Bramley, was summoned on a similar charge. His case was also adjourned.—*Leeds Mercury.*

At the Hanley Borough Court on Monday, Mr. E. S. Insull was charged with having sold some precipitated sulphur, which the certificate of Mr. Scott alleged was grossly adulterated, and would be extremely injurious to health, especially in the case of children or persons of delicate constitution. A fine of 10*s.* and costs was inflicted.

ALLEGED ADULTERATION OF SCAMMONY.

On Monday last Mr. George Brown, chemist and druggist, Bryan Street, Hanley, was charged at the Hanley Borough Court, with having sold as unadulterated a shilling's worth of powdered scammony which was adulterated.

Mr. Fulford, in opening the case, said that scammony was largely used by medical practitioners, and if it were not pure serious injuries might result to patients. He apprehended that the only point in the case would be as to whether the scammony was as pure as could be got. He might mention, with respect to the certificate of Mr. Scott, county analyst, that, although it was stated the scammony was adulterated, the proportion of the adulterants was not given. Mr. Scott ought to have given it.

The Stipendiary: Mr. Scott has personally promised me he would state the proportion of the adulterants in such cases.

Mr. Smith stated for the defence that scammony was a kind of gum, procured from a tree, and was never imported to this country pure. There was always a certain percentage of resinous matter in it. He called Mr. R. G. Smith, druggist, from the establishment of Messrs. Evans, Sons, and Co., Liverpool, who said that he never knew even the so-called virgin scammony imported without having from 20 to 30 per cent. of impurity. Mr. Smith said that the Eastern growers allowed the impurity for the purpose of preservation. He submitted that, under the circumstances, Mr. Brown could not be held to be responsible.

The magistrates held a different view, but considered a fine of 10*s.* and costs sufficient to meet the justice of the case.—*Staffordshire Daily Sentinel.*

ADULTERATED PEPPER.

At Leeds, Patrick Ford, grocer, has been summoned for selling pepper adulterated with extraneous starchy matter to the extent of 26 per cent., and was fined 5*s.* and costs.

Joseph Nichols, chemist and druggist, for selling pepper adulterated with pea-flour to the extent of 50 per cent., was also fined 5*s.* and costs.

The Morning Tonic Case.—Correction.—We are informed that there is an error in our report of this case on p. 639, col. ii., line 47. The stipendiary magistrate having attributed to Mr. Harkness a statement that "pick me ups" sometimes contain 40 per cent. of solid matter, and not 10 as it appears in our report. We may remark that the error is due to an intentional alteration on our part. The reporter's notes gave the amount as 40 per cent., but the statement appeared to be so extraordinary, that it was attributed to an error in reporting, and the alteration was made to the more probable amount of 10 per cent. in accordance with the evidence of Mr. Baynes, jun.

BOOKS RECEIVED.

NOTE-BOOK OF MATERIA MEDICA, PHARMACOLOGY, AND THERAPEUTICS. By R. E. SCORESBY-JACKSON, M.D., F.R.S.E., etc. Third Edition. Revised by Dr. ANGUS MACDONALD, M.A., F.R.S.E. Edinburgh: Maclachlan and Stewart. 1875. From the Publishers.

THE ANALYST'S ANNUAL NOTE-BOOK. By SIDNEY W. RICH. London. 1875. From the Author.

MANUAL OF PUBLIC HEALTH FOR IRELAND. By THOMAS W. GRIMSHAW, M.A., M.D.; J. EMERSON REYNOLDS, F.C.S.; ROBERT O'B. FURLONG, M.A.; and JOHN WILLIAM, M.D. Dublin: Fannin and Co. 1875. From the Publisher.

A MEMOIR OF THE LADY ANA DE OSORIO, Countess of Chinchon and Vice-Queen of Peru (A.D. 1629-39); with a Plea for the correct spelling of the Chinchona Genus. By CLEMENTS R. MARKHAM, C.B., F.R.S., etc. London: Trübner and Co. 1875. From the Publishers.

Notes and Queries.

HARMLESS FACE POWDER.—Mr. Hans M. Wilder states (*Amer. Journ. Pharm.*) that the apothecaries in Copenhagen (Denmark), have agreed on the following two compositions as substitutes for the numerous, generally poisonous, fashionable face powders:—

White.

Oxide of Zinc	30 grms.
Wheat Starch	250 „
Oil of Rose	3 drops.

Red.

Carmine	1 grm.
Carbonate of Magnesia	4 grms.

[426]. JOCKEY CLUB BOUQUET.—In reply to J. Minro's inquiry, the following is taken from Piesse's 'Art of Perfumery':—

Extract of Orris Root		2 pints.
Esprit de Rose Triple		1 „
„ „ Rose, de Pommade		1 „
Extrait de Cassia	of each	½ „
„ „ Tubereuse		
„ „ Ambergris		½ „
Otto of Bergamot		½ „

[427]. MARKING INK FOR STAMPING.—I shall be glad if any correspondent will publish a formula for a permanent ink for marking linen which can be used satisfactorily with metal types.—INQUIRER.

Obituary.

SAMUEL MANTHORP.

We regret to have to announce the death, on Monday, the 1st of February, of Mr. Samuel Manthorp, Pharmaceutical Chemist, of Colchester, aged 66. Mr. Manthorp had been in business upwards of 41 years, was one of the founders of the Pharmaceutical Society, and from its commencement acted as its local secretary.

The high moral character and intellectual attainments of the deceased gentleman won for him the esteem, not only of his brethren in the business, but of all who knew him.

Notice has also been received of the death of the following:—

On the 14th November, 1874, Mr. Thomas McNay, Chemist and Druggist, of Barrow-in-Furness.

On the 6th January, 1875, Mr. John William Wells, Chemist and Druggist, of Castle Street, Oxford Street.

On the 8th January, 1875, Mr. Thomas Evans Edwards, Chemist and Druggist, of Bath.

On the 19th January, 1875, Mr. William Mansell, Chemist and Druggist, late of Plough Court, Lombard Street.

On the 22nd January, 1875, Mr. James Sawyer, Pharmaceutical Chemist, of Carlisle. Mr. Sawyer had been a member of the Pharmaceutical Society since 1842.

On the 23rd January, 1875, Mr. John James, Pharmaceutical Chemist, of Truro. Mr. James had been a Member of the Pharmaceutical Society since 1842.

On the 25th January, 1875, Mr. Benjamin Bullus, Chemist and Druggist, of Fareham. Mr. Bullus had been a member of the Pharmaceutical Society since 1870.

On the 28th January, 1875, Mr. Robert Bradshaw, Chemist and Druggist, of Cheltenham.

On the 1st February, 1875, Mr. Joseph Edwards, Chemist and Druggist, of 11, New Cavendish Street, London.

On the 2nd February, 1875, at 3, St. George's Circus, London, S.E., Mr. Stephen Francis Solly, Pharmaceutical Chemist, aged 67. Mr. Solly had been a Member of the Pharmaceutical Society since its formation.

On the 4th February, 1875, Mr. John Taylor Illingworth, Chemist and Druggist, of Bradford.

On the 8th February, 1875, Mr. James Peel, Pharmaceutical Chemist, of Stockwell Road, Surrey. Mr. Peel had been a Member of the Pharmaceutical Society since 1873.

Correspondence.

Pharmaceutical Examinations.

Sir,—It is with some hesitation I write a few lines on the subject of the "examinations." So frequently in past time, has this subject been discussed and most likely will be again, that there is not much fresh ground to go over. It will, however, be a vexed question with many, until the returns show a greater success on the part of the examined, whether the examinations are too stringent or the candidates too deficient.

The summary in your January number shows a large total of 668 rejected candidates who presented themselves for the Minor and Major examinations. Surely this cannot be the fault of the Board of Examiners. Then there is only one conclusion to arrive at, that those who present themselves are lamentably wanting in pharmaceutical knowledge and have not availed themselves of the opportunities which the Society offers, and I fear this will continue to be the case until all are compelled to enter on a curriculum of study, for certain appointed terms, and at properly recognized schools of chemistry, before commencing the business of a pharmacist.

The principal point, however, on which, Mr. Editor, one is desirous of eliciting information is, regarding the obtaining of honours. I see in the course of the year 1874 only 8 obtained honours out of a total of 51 who presented themselves for the Major examination.

Now this is a small ratio, and causes some surprise, one is quite ignorant as to the requisite qualifications for the much-coveted distinction. Where is the line of qualification drawn? Is it merely at the option of an interested bias on the part of the examiners—by the word interested, I mean as regards the quick, prompt, ready, intelligent replies of the candidates—or is there a definite standard to be reached? If so, what is it?

I have been personally acquainted with many young men who have studied hard, worked well and long at the laboratory at Bloomsbury Square, were highly thought of by their instructors, still more, on presenting themselves for examination have completely satisfied their examiners, so far as they could ascertain, and yet failed to receive honours. Lately one gave me the questions which were put to him and the answers that were given; he mentioned the analyses he performed, and both answers and results of analyses were correct and explicit,—I was surprised that honours were not obtained.

Now is it not a point worth considering:—The good effects of granting honours more frequently, where it can fairly and honourably be done? The bestowal of honours gives a further impetus to study, it holds out a prize worth obtaining, it often prolongs a stay at the laboratories, and encourages students to follow on investigations and researches in chemistry and other sciences which otherwise they might cease to do. Surely a little more liberty, a little more latitude in bestowing honours could do no harm, and might be of lasting benefit to many.

Mr. Schacht has warmly advocated the founding of scholarships and interested himself zealously in the cause of pharmaceutical education, but if the prize, or rather the means of obtaining the prize (for to compete for the scholarships the student must first, by the present regulations have obtained honours) is debarred to so many, it would seem almost useless to adopt the plan. A few more months of study, encouraged by the giving of honours and the hope of a prize of scholarships would materially advance the interests of many of our students and ultimately bring forward more good men to the front rank of pharmaceutical science.

Just one other remark. In all boards of examiners there are always one or two who are especially dreaded by the students. We remember hearing in our early days—and the same remark is made in the present time—"I hope I shall not have Mr. —— to examine me," or, again, "if it had not been for Mr. —— I should have passed." This last remark is a very favourite one, but entirely fallacious and does not and never did bear any truth. No candidate was ever yet rejected at the option of one examiner. Still the fact remains, that in all boards of examiners one is generally singled out as a severe, hard, and unjust task-master. This must be an unenviable notoriety and also an unnecessary one; it is quite practicable to be *fortiter in re*, as regards the questions asked, and yet combined with the *suaviter in modo* as to the way of asking them.

Strand, Torquay. JAMES B. GUYER.

Pharmaceutical Remuneration.

Sir,—Your correspondent "Veritas" has written a good letter at page 580, as is proved by the numerous comments made upon it; but his £1,000 a year must be taken *cum grano salis.*

My experience teaches me that a man, who has been confined for years to a retail business, will have formed such economical and frugal habits as to be able to retire on a much smaller income.

To young men who feel the difficulties of commencing business I would recommend the reading of the 'Memoir of John Bell,' at page 589 of the eighth volume of the *Pharmaceutical Journal*, dated June, 1849, edited by his son, Jacob Bell.

This obituary of John Bell will teach young men of nervous timidity not to despise the day of small things; and the over-confident men, who dream of £1,000 a year, may read it with benefit.

"Take physic, pomp;
Expose thyself to feel what wretches feel;
That thou may'st shake the superflux to them,
And show the heavens more just."

Without disparaging the present series of the *Pharmaceutical Journal*, the first eighteen volumes, edited by Jacob Bell, contain much valuable information, and many practical suggestions.

JOSEPH LEAY.

Downside, Chilcompton, Bath,
January 30, 1875.

Sir,—One conclusion at which I arrive from perusing several of the attacks made on "Veritas," is that some of your correspondents are not very good arithmeticians or financiers. They appear to be utterly ignorant of the fact that money placed at interest at 5 per cent. doubles itself in a little over fourteen years. "Amor Veritatis," who seems to think the whole statement of "Veritas" an absurdity, and the doubling of the fortune during the last ten years its climax, betrays the ignorance I have intimated. Allow that a man, under the circumstances indicated, could secure an income of £500 by the time he was forty, it would be an easy matter to make it £1,000 by the time he was fifty. Mr. E. Nuthall says an average saving of £800 is required to accumulate £20,000 in twenty-five years. Instead of that being the fact, £800 put by each year for twenty-five years would amount to £38,181, and if the man commenced business at twenty-four instead of twenty-five, at fifty his savings would be £40,890. Judging from the letters of "Veritas" I certainly conclude that he is unlikely during his business career to have "hid" either his mental or metallic "talents in the earth," or "kept them laid up in a napkin." The *naive* simplicity with which some of that gentleman's opponents write, as if they expected in purchasing a business the returns would, like the laws of the Medes and Persians, never alter, leads me to entertain the belief, which I gather is that of "Veritas," that a large percentage of druggists are not overburdened with business ability, and, as a consequence, are not likely to be overburdened with business.

Does Mr. Nuthall suppose there are no businesses more profitable than the one indicated in his hypothesis? If so, his experience must be of a very "mixed" character.

MAGISTER.

Sir,—On reading the letter of "Veritas," I was much struck by the following most encouraging statement, which parents and guardians, in these days of competition and over-crowding in every branch of commercial life, would do well to lay to heart; he says, "It is a business in which a young man, with £200 or £300 to commence with, may confidently hope to retire on £500 a year by the time he is forty, or on £1,000, by the time he is fifty, and only one qualification absolutely necessary," he must be a man of business. Very good; that is to say this wonderful young man of business, who starts for himself say at the age of twenty-five (few begin sooner) with £300, in fifteen years finds he has amassed £10,000, which at 5 per cent. will bring him in £500 per annum, and if he only has the perseverance to hold on until he is fifty, which at the rate he is making money he is most likely to do, he finds that in ten years he has doubled his capital, and that now he can retire with something like dignity on £1,000 a year. And this is not an isolated case, but in the experience of "Veritas" no doubt has been accomplished over and over again. "Veritas" believes in even better times than these for the druggists of the future. What the man with a larger capital than £300 may achieve, I presume it is beyond even the pen of "Veritas" to describe; in the meantime, let us be thankful that we are not as other trades are, ironmongers, hatters, or even as this "Examined Assistant."

NIL DESPERANDUM.

January 19, 1875.

Sir,—There is nothing so very doubtful about the statement of "Veritas." I have £500 per annum; commenced business twenty years ago on a capital of £300, and am a little over forty years old. The secret of success may be summed up thus:—An examination diploma, civility, not servility, and work. I live in a small town, and have always kept my head well up. I have a family of three, keep two servants, and never unduly screw or pinch for the purpose of acquiring more cash.

I enclose my name and address, but not for publication.

A WORKING MAN.

Sir,—When I ventured to question the reasonableness and practicability of the proposition of assistants studying certain books during the hours of business, and the practicability of the further proposition of druggists closing their shops so early and so regularly as hatters, grocers, drapers, and ironmongers, I had no idea of provoking so great a controversy. Several of your correspondents, especially those who put direct questions to me, were I not to reply, might naturally construe my silence into discourtesy or inability. I therefore apprehend you will not refuse me the privilege of rendering them an answer, I promising that regard for the value of your space, not to mention respect for the value of my own time, will insure this being my last say. I trust that each one who has honoured me with his notice will find that I have not failed to heed his communication, although with so many to answer my reply must necessarily be more or less of a general character.

I respectfully contend that I have proved the two things I attempted to prove, and that my opponents virtually, though unintentionally, admit it. There would be little utility in repeating my arguments and re-slaying the slain. By some of your correspondents more ire than argument is apparently exhibited—I say apparently, for perhaps the anger is more seeming than real; at all events, there is no necessity, even though difference of opinion exist, why we should not agree to differ, and write and feel amicably.

"An Examined Assistant" is far less lucid in his last than in either of his former letters. In the last sentence of the third paragraph in his recent one he is quite incoherent. Retrogading to one or two of his preceding lines, I may observe that "the method of reasoning adopted by 'Veritas,'" certainly does not necessitate "the shutters being down and the gas flaring in the night;" neither did I intimate that I kept my "shop open till a very late hour." In this city the shops are ostensibly closed at six, and I heartily wish that they could be then closed physically (I don't intend a pun) until the next morning, but I cannot see the way, for the reasons given in my former letters, to its accomplishment. I often venture to remonstrate with customers who apply for articles late in the evening which might well be obtained earlier in the day, and I never complain if my assistants do so too. I have sometimes thought the evil might be remedied if all would combine to charge double price for articles supplied after a certain hour, but it is so difficult to get universal *bonâ fide* combination for such purposes.

I think the plan adopted at Bedford an admirable one. It doubtless answers especially well in so exceptional a place, where there appears to be scarcely an establishment with only one assistant or apprentice. My thanks are due to Mr. Waring for his explicit reply to my inquiry; he has excited in me an especial interest in Bedford. I am seeking for one of my sons an eligible opening for starting in business; I often visit a neighbouring town, and I purpose the next time I do so "taking stock" of Bedford, when I may have the honour of making Mr. W.'s acquaintance. Meanwhile, should he know of a house or shop to let in a good situation he will add to the favours already conferred by informing me of it. I note an apparent difference in Mr. W.'s two letters: in the first he says only one assistant "stops in," in the second he seems to intimate that while one attends to late customers, the others are engaged in study. Do they go out to study? and if so, where? Given that there are a dozen druggists in Bedford employing three or four assistants or apprentices, say that twenty are set free at seven, how many of the twenty pass the three or four hours at their disposal in study, and how many at billiards, or some kindred amusement, or in discussing a pipe, or "a weed" with "bitter?" If any do pass their evenings in either of these latter ways, I warn them that so far as their future welfare is concerned, it would be ten thousand times better that they should be kept to the very latest hour behind the counter that obtains in the most heartlessly conducted establishment in the kingdom. I cannot conceive anything that would have been more delightful and jolly than to have been able thus to pass my evenings when an apprentice and assistant; but if I had, where should I be now? Certainly not where I am. I should long since have gone—to use a figurative expression—to the devil, where I have known many go in my time. Again, Mr. W. says in his first letter that "only medicine is supplied" after seven, while in his second letter he says, "it is not necessary to keep all in for the sale of sponges, etc., etc." Now, which is to be understood, does the one assistant supply with undeviating strictness only medicine, or does he supply any article a customer desires who gains admission after seven? If all the druggists' shops have private doors I can understand the possibility of restricting sales to physic; but it strikes me it would be extremely difficult to practice if customers be admitted to the shop. A customer requires medicine, sees a box of tooth powder on the counter, and says, "I will take that." Would every druggist in Bedford, loyal to his fellows, say, "No, I can't let you take it, you must come to-morrow for it?" Lastly, I would ask Mr. Waring what hour is fixed for really closing, locking up for the night, or is there no fixed hour, but procrastinating people can come and worry the one assistant as late as they please? I need hardly repeat my contention, that a shop is not really closed so long as even one assistant is in attendance to respond to applicants.

The replies to my question, why some gentlemen prefer not to have a "Square" man (I never said I did) are not satisfactory; such considerations as those suggested would, I am sure, not influence those whom I have heard of as expressing such a preference. I have been credibly informed of one gentleman entertaining such preference (or shall I say prejudice?), whose name stands as high in connexion with British pharmacy and the Pharmaceutical Society as that of any man. Does not "scientific knowledge" *per se* add to the value of an assistant's services? I should certainly desire to choose that assistant whose services would be the most valuable. Mind having an assistant whose knowledge surpassed my own? Why, the shop or the laboratory would be transformed into a paradise, so far as the principal would be concerned, if he had nothing to impart but only to acquire—like the bee, gathering honey all the day from every flower.

I am perfectly at one with Mr. A. Warren in the sentiment expressed by him in the last sentence of his letter. There is no antagonism between it and what I said. He thinks there is: he clearly ignores altogether the all-important, utterly-indispensable qualification on which I laid such emphasis. I thank "Observer" for so well expressing what are my sentiments, as well as his own.

I propose to refer to certain incidents and circumstances which have fallen under my notice during the last thirty years or so, and therein Mr. A. Warren, "A Young Observer," "H. J. O." and Mr. R. Huggins, must look for a reply to their remarks or questions. I mentioned in my first letter something of the early history of a druggist's apprentice. During the latter years of his apprenticeship the business which eventually became Mr. Henry Deane's was for sale for £450. I have heard that apprentice say he would almost have given his ears to have been a few years older and possessed of £450, convinced that there was a fortune to be made by any man of business who might become the fortunate purchaser. Two or three persons failed to obtain a livelihood in it before Mr. Deane purchased it.

Some time between the years '40 and '50, the apprentice having £50 or £60 of his own, borrowed £200 at five per cent. interest, and started in business. After nine months he came to the conclusion that he would certainly never make a fortune in the locality he had chosen. His returns had not reached anything like £300 per annum; so one Friday he put an advertisement in the *Times* offering the business for sale. It brought him four applicants, to all of whom he shewed his daybook, ledger, and prescription and cash books, and within three days he had parted with it for £400, and went out £100 richer than he went in, nine months before. In the course of a few months he started again. His first year's returns in this second venture were £450; this he considered a fair success. Last year he turned over about £2,200, and for a good many years his returns and profits have been what folks would call considerable. I adduce him as an instance of a man, commencing with £200 or £300, being able to retire on £500 at forty and £1,000 at fifty. He says if his time were to come over again, he could—like many others—do much better, avoiding a good many blunders which during his career he made. He further says that he never knew the want of a pound or a shilling, that he never was unable to pay a traveller the full amount of the account he presented, and never gave a bill in his life, save for the loan of the £200. "Oh," some of your readers may exclaim (if I do not anticipate them), "you are depicting the career of some miserly curmudgeon —bachelor, perchance—'a wretch concentred all in self,' who never had a thought for a fellow creature, and whose sole interest was, if possible, to save all he earned." Not so; I do not know anyone who has apparently more keenly enjoyed existence. He was wont, when an apprentice, to say, "My first aim will be to keep myself, my second to keep a horse, my third to keep a wife;" and he succeeded in his aims, in the order he had prescribed; and I know no one who is more delighted than he to entertain those "who can talk of old friends" and old scenes "and old times."

There is a druggist's shop in a town within twelve miles of this which probably has been a druggist's shop some forty or more years. During the first half of its existence it had many owners, none of whom succeeded in getting a living, and I fancy its maximum returns seldom much exceeded £600: as it was in the principal street the rent and expenses were considerable. During the latter half of its being it has been in the hands of one proprietor. I estimate his present returns at something like £3,000, and he would not be likely to accept in exchange for it five times the amount for which he purchased it. His success has been far greater than that of my friend the apprentice of "the good old times." I know two businesses in another town in England in near juxtaposition. Somewhere between '48 and '50 one was purchased for £800. A year or two later the other was to be bought for £300 or £400. It was purchased by a quaker. Quakers generally know how a business should be conducted. His business would now be a bargain at considerably over £2,000, while I should hesitate to give for the other a higher sum than that at which it was sold twenty-five years since. Why this alteration in their values? Why, one has been managed in a manner it would be impossible to surpass, while the other has not. Thus we see man after man going to the wall, until one succeeds them who rapidly acquires a fortune, proving the truth both of Mr. Warren's affirmation and my assertion. "But," says Mr. Huggins, in his classic phraseology, "you haven't explained the 'clever trick' by which the small capitalist, or rather no capitalist, can certainly acquire a competency?" Here it is: he bears

"A banner with the strange device—"

"Rigid economy—(the fare of an anchorite, if needs be)— untiring industry—judicious enterprise—indomitable perseverance." Lastly, he who carries it must be a man of business, or he will find no more talismanic effect in his banner than in a dirty rag.

VERITAS.

January 26, 1875.

THE CHEMISTRY OF THE TAR ANTISEPTICS.

Sir,—I notice in your impression of the 9th ult. a paper entitled "The Chemistry of the Tar Antiseptics," which was read by Mr. W. E. Bickerdike before the Liverpool Chemists' Association, December 17th, 1874. The author, I see, admits the subject matter to be but imperfectly described by the title of his paper, and as the information he has attempted to convey seems to me to be equally misleading, I trust you will allow me a space in your valuable Journal, to draw attention to a few of the points on which correct information might have been of real value to your readers.

In describing the preparation of crude carbolic and cresyllic acids, Mr. Bickerdike begins by giving a very much too general outline of the process of coal gas tar distillation. Coal gas tar differs so much in character from the relative proportions present of products solid or fluid at natural temperatures, that no one process of distillation and separation is applicable to them generally.

So much so is this the case, that to take an example:— From Manchester coal gas tars the bulk of the mixed crude carbolic and cresyllic acids is extracted from the "light oils;" while from the London coal gas tars the bulk of the mixed crude carbolic and cresyllic acids is obtained from the heavy oils or creosote, stated by Mr. Bickerdike to contain cresol only, and to be employed without further treatment for saturating railway sleepers.

Mr. Bickerdike proceeds to state—"The further separation of phenol and cresol from the crude liquid is effected by repeated fractional distillation, assisted by crystallization of the phenol, from which the liquid cresol can be removed mechanically." Should Mr. Bickerdike employ no other means of purification than those described in his paper, I can only state that neither the phenol nor cresol so obtained is fit for surgical use or disinfection, containing as they would, free sulphur, many sulphuretted compounds, tar bases, etc., etc. Neither does the phenol constitute the B. P. quality first introduced for surgical and disinfecting purposes by my former partner, the late Dr. F. Crace Calvert.

Mr. Bickerdike next proceeds to describe pure carbolic acid, or as he calls it, absolute phenol, and any one reading the text of his paper would suppose it a description of a product newly obtained, manufactured and first described by him, the fact being that the product in question is well known in the trade, being manufactured by our firm and that of F. C. Calvert and Co., under the protection of letters patent, by the ton, and that a full description of the product and process of its manufacture were published simultaneously by the late Dr. F. C. Calvert and the writer, in 1867. Mr. Bickerdike's partner, Mr. Bowdler, (a chemist for some time in the employ of the late Dr. Calvert,) should have been able to give him more correct and extended information with regard to pure carbolic acid and its properties than displayed in his paper. Dr. Calvert gives the boiling point of pure phenol as 182° C., Mr. Bickerdike at 184° C. The writer's results agree with those of Dr. Calvert, and he can further add that these two degrees of difference in boiling point indicate a material impurity in the acid boiling at 184° C., in a scientific point of view.

As regards the non-deliquescent properties of pure phenol, Mr. Bickerdike does not seem to have recognized the fact that pure phenol attracts moisture from the air like pure cresol, but as the product in the former case is a solid crystalline hydrate at natural temperature, and in the latter case a liquid hydrate, the physical result of the action of moisture on a mixture of the acids must necessarily be more apparent than that shown by the pure phenol. With respect to Mr. Bickerdike's discovery (?) of "granulated phenol," probably most dispensers will have found it convenient to grind up in a mortar a portion of their stock of the pure phenol, but not advisable to prepare any great bulk in this state, as a summer temperature would certainly reconvert it into an adherent mass by a process of semi fusion and regelation.

Mr. Bickerdike states "that when phenol is heated with certain metallic oxides and an alkali, rosolic acid is produced."

This statement is absolutely incorrect, no such product being formed as proved by Caro years ago, who showed that the results obtained by Drs. Smith and Jourdin were due to the oxydation of the mixture of carbolic and cresylic acids constituting the impure acid used in their experiments, and that pure carbolic acid under the conditions above referred to, yields no rosolic acid. Mr. Bickerdike's description of the manufacture of rosolic acid (named aurine by writer when first introduced by him as a dye stuff), and its properties is now much less incorrect. As regards the manufacture it is really prepared by the prolonged action of heat (with a subsequent washing, etc., of the mass obtained) on a mixture of carbolic, oxalic, and sulphuric acids, in which the greater proportion of the carbolic acid is uncombined, or at lest not present, as sulphophenic acid.

Mr. Bickerdike's statement that "By the removal of unchanged phenol from the aurine of commerce, it may be obtained in a crystalline state," is also incorrect. The researches of Messrs. Dale and Schorlemmer on aurine have fully proved that the residue thus obtained would contain a very high percentage of other products, some being even colourless.

With regard to the manufacture of picric acid, it is now seldom if ever prepared by the direct action of nitric on carbolic acid, as described by Mr. Bickerdike, but by the action of nitric acid or nitrates on sulphophenic acid, either in water or sulphuric acid solution, with subsequent boiling, washing, and crystallizing processes.

The above remarks will sufficiently indicate the crude misleading nature of the information contained in the paper under review, and trusting their object will be sufficient apology for trespassing on your valuable space and the time of your readers.

CHARLES LOWE.

Manchester, February 3, 1875.

MILK OF SULPHUR.

Sir,—After reading your remarks upon precipitated sulphur and milk of sulphur in last week's *Pharmaceutical Journal* I came to the conclusion that at present I could not agree with your opinion, viz., that precipitated sulphur is not milk of sulphur. All the authorities that I have looked up agree in giving milk of sulphur as a synonym for precipitated sulphur, viz , Pereira, Royle, Attfield in his 'Pharmaceutical Chemistry,' Redwood in Gray's 'Supplement,' Scoresby Jackson, Ince in a paper read before the Pharmaceutical Society, 1842, Wittstein, by Darby, Neligan, and Paris. I do not contend that there is not a formula for lac sulphuris where it is ordered to be prepared with sulphuric acid, but what I do contend for is this, that that formula was found to be a bad one, and produced an impure product, and was subsequently improved by substituting hydrochloric for sulphuric acid which produced a purer product. Also I contend that the changing of the name from lac sulphuris to precipitated sulphur is really of no importance, as the former name would be given when old or barbarous names were in use, such as spiritus salis ammoniaci, tartarum solubile, and that it was not changed because sulphur præcipitatum was a different article, but changed like as the names spiritus salis ammoniaci and tartarum solubile were changed to spiritus ammoniæ and potassæ tartras, to be more in keeping with chemical knowledge, and to show the composition. I shall be glad if you will introduce this note amongst your correspondence, and perhaps it will elicit the opinions of more in the trade.

JOHN HALLAWAY.

52, Castle Street, Carlisle,
February 9, 1875.

[*** We fully agree with the spirit of these remarks, but cannot shut our eyes to the fact that the term milk of sulphur is still popularly associated with the old preparation containing sulphate of lime, although that has been pharmaceutically superseded by the much better preparation—precipitated sulphur.—ED. PH. JOURN.]

K. B.—No.

Q. S.—There is nothing in the label that would constitute a breach of the Pharmacy Act.

Inquirer.—(1) See Notes and Queries column. (2) See directions for coating pills in vol. iii., p. 467, and vol. iv., pp. 575 and 953 of the present series of this Journal.

W. Glass.—The "Pulvis Liquiritiæ compositus" of the 'Pharmacopœa Germanica.'

Misceantur.

"*England.*"—The "lead tannin" process was described by Mr. Allen in the *Chemical News* for May 1, 1874.

J. W. Sindall.—We agree with you that mercury is not antimony; but nevertheless "cinnabar of antimony" is an old name given to the sulphide of mercury which is left in the retort when perchloride of mercury is used in the preparation of chloride of antimony.

W. B.—*Bath Pipe.*—"Extract of liquorice, 1 oz.; powdered gum arabic, 1 oz.; white sugar, 1 lb.; hot water, q.s. to form a mass; to be rolled into pipes." (Cooley).

A. B.—We do not know the preparation.

A. P. S.—If you are correct in your observation we do not think the sediment can be avoided. A "Shake the Bottle" label should be used.

G. R. B.—We do not know.

E. Kemp.—The shell of the cephalopoda is sometimes external and sometimes internal. In the family of the *Sepiadæ* it is internal and is in the form of a broad calcareous plate. It is this that is known as "os sepiæ."

C. Jarvis.—The formula has not yet appeared in this Journal during the present year, but it may be found at p. 610 of the last volume, and with variations, at p. 849 and p. 891.

N. M. Barnes.—Barber's 'Pocket Companion to the Pharmacopœia' is published by Philip and Son, Fleet Street, price 5s.

"*Spes.*"—(1) We should expect that a person presenting himself for the Minor examination, unacquainted with a subject included in the Preliminary syllabus, would stand a good chance of being "plucked." (2) One or two or more substances may be present. (3) No. (4) 'The Calendar of the Pharmaceutical Society' for 1875 will be ready in a few days. (5) Stephenson and Churchill's 'Medical Botany.'

J. Whitfield.—Whether the article in question requires a patent medicine stamp depends upon what the Inland Revenue authorities may consider it to be. We have forwarded the handbill to them for their opinion, and will report their answer when we receive it.

A. P. S.—The transparent specimen sent corresponds with a transparent specimen of the so-called "Gum Cowrie," which is now imported into this country in considerable quantities. Concerning its origin see a letter in the present volume, *ante*, p. 259.

"*Investigator.*"—So far as the article termed "benzoline" is prepared from petroleum, it may be correctly termed "petroleum." The legal definition of "petroleum" comprises any hydrocarbon oil which has a flashing point below 100° F., whether it be prepared from petroleum, coal oil, or analogous sources. The licence to sell benzoline has reference to "petroleum" as defined by the Act.

T. Walker.—The point is one that can only be settled by experiment. We shall be glad to be informed of the result.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Thresh, Dr. Gray, Mr. Smith, "Minor," "Theta," J. S.

CARNAUBA ROOT.

BY CHARLES SYMES, PH.D.

Two bales of this root have been imported into Liverpool, with the following remarks in Portuguese:—

"A raiz da carnauba é um excellente depurativo ja reconhicido por varios facultativos i pelos mesmos applicada na cura de muitas molestias que tem sua sede primordial na impureza do systema sanguineo circulatorio. Causa pasmo e admiracao o despreso que ainda tem a referida raiz rival da salsaparrilha pelas suas qualidades therapeuticas, merecedora de toda confianca. A raiz da carnauba tem tambem vertudes diureticas, segundo somos informados, e é extremamenté efficaz na cura das blenorrhagias que agudas quer chronicas. E um bom refrigeranté mas como depurativo do sangue é da uma accão vigoroso, como tem demonstrado a expériencia."

Which in English might be rendered thus:—

"This root is recognized by the profession as an excellent purifying agent and has been successfully applied in the cure of various diseases arising from impurity of the blood. We are indeed astonished that it is not more widely known, as its therapeutic qualities, which are worthy of full credence, rival those of sarsaparilla. The carnauba root, likewise has a diuretic power and possesses unusual efficacy in the cure of acute or chronic blennorrhœas. It is, furthermore, very cooling and displays a vigorous action in purifying the blood."

The root is that of *Corypha cerifera*, a wax-bearing palm, growing on the shores of the Rio Francesco, in the Brazils; it is several feet in length and has an average thickness of three-eighths of an inch, of a mixed greyish and reddish-brown colour, giving off here and there small rootlets.

The cortical portion is comparatively thick, somewhat friable and loosely surrounds the meditullium which encloses the pith; thus a transverse section somewhat resembles in appearance an exogenous stem. Its infusion is similar in colour to that of wild cherry bark, possesses an agreeable, slightly bitter taste and an odour not unlike that of sarsaparilla; its colour is slightly deepened, but no precipitate occurs, on the addition of liq. potassæ; neither on the addition of dilute acids. Tinct. ferri perchlor. does not strike a black, but brownish colour, gradually followed by turbidity and the formation of a brown deposit. The decoction is not affected by iodine, indicating the absence of starch; a drop of it concentrated on a porcelain slab and treated with strong sulphuric acid produces an olive green, slowly changing to a brown colour. It yields 25 per cent. of a reddish-brown extract possessing a decidedly bitter taste.

It awaits further medical testimony in this country; should it prove equal to the particulars given it will be a valuable medicine, and possesses the advantage of an almost unlimited supply, at (I am informed) about one-half the cost of sarsaparilla.

Liverpool, February 12, 1875.

NOTE ON PURE PHENOL.

BY W. E. BICKERDIKE, F.C.S.

In a paper on the chemistry of the tar antiseptics, reported in the *Pharmaceutical Journal* of 9th ult., I stated that pure phenol was not deliquescent, and that the disposition to attract moisture which ordinary commercial phenol possesses is owing to a slight contamination with cresol. This statement was controverted by Mr. C. Lowe in a letter in the Journal of the 13th inst., the writer of which says that pure phenol absorbs water from the atmosphere like pure cresol, the only difference being that the hydrate in the former case is solid at ordinary temperatures, and in the latter case liquid. As this statement is at variance with my experience, I have compared the two bodies with reference to the above property. The results of the examination are detailed below.

Pure and recently distilled phenol was broken into small fragments, and exposed to a moderately damp atmosphere in an open platinum dish; the quantity of phenol taken was 3·99 grams. The weight of the vessel and its contents was taken at intervals, and was found to undergo a steady decrease, amounting at the end of eighteen hours to ·04 grams, or one per cent. This loss was owing to the slow volatilization of the phenol, which had not been balanced by the absorption of water. At the same time a quantity of cresol weighing 6·42 grams was exposed under exactly similar conditions; the weighings were taken as before, and, notwithstanding the loss from volatilization, the weight of the cresol increased from absorption of water, so that at the end of twelve hours the gain in weights amounted to 4·67 per cent. These results confirm my previous statement with respect to the very different behaviour of phenol and cresol in absorbing moisture from the atmosphere. On the other hand a sample of phenol which contained a small percentage of cresol, did absorb moisture without becoming liquefied, and this may account for the phenomenon which Mr. Lowe describes.

It might be supposed, that although phenol does not absorb moisture like cresol, yet it may do so more slowly, without any indication being given by an increase of weight in consequence of the loss from volatilization.

In this case the crystallizing point would be considerably depressed, as the hydrate melts at 16° only. In order to test this a larger quantity of the pure phenol was exposed for twenty-four hours on an open tray; on examination it was found that the fusing point had only been altered half a degree, showing an absorption of moisture quite insignificant.

THE EMPLOYMENT OF COAL OILS IN THE PREPARATION OF ALKALOIDS, ETC.

BY G. BOIRAUX AND E. LÉGER.

(*Concluded from p.* 643.)

Strychnine and Brucine.—These two alkaloids exist in about equal proportions in nux vomica seeds; whilst in the strychnos bark brucine predominates and brucine in St. Ignatius' beans. The following is the authors' method for obtaining the two alkaloids at the same operation:—1000 grams of grated nux vomica seeds are boiled during an hour with 6 litres of water and 20 grams of sulphuric acid; then during half an hour with 4 litres of water and 10 grams of acid; and finally during half an hour with 4 litres of water and 5 grams of acid, the marc being pressed strongly after each boiling. The three products are evaporated to 4 litres and precipitated by a sufficiency of milk of lime. The dried precipitate is treated in a displacement apparatus with sufficient cold carbolized coal oil to give 500 grams of percolate, and this is distilled with a solution of 15 grams of tartaric acid in a litre of water until all the benzine has passed over. About 500 grams of aqueous solution of the tartrates of strychnine and brucine are left, with sometimes a little fat or resinous matter floating on the top. The solution is filtered and precipitated with ammonia; the product washed and dried is a white powder consisting of a mixture of strychnine and brucine. To separate them advantage is taken of the solubility of the former and complete insolubility of the latter in the lighter oils. The mixture is placed in a small flask and heated in a water-bath during a quarter of an hour with a sufficiency of benzol, then decanted upon a filter; the operation being repeated until a few drops evaporated upon a watch glass give a residue coloured red by nitric acid. The solution upon evaporation gives abundantly crystals of brucine.

To obtain brucine alone decoctions are made with 1000 grams of strychnos bark, as with the seeds, 60 grams of acid being used for the first operation and 30 grams for each of the others; the liquors united are evaporated to one litre, and precipitated with a sufficiency of milk of lime. The precipitate, weighing about 125 grams, is heated in a water-bath with 500 grams of coal oil, and the whole thrown on a filter; the marc is washed with 500 grams more of hot coal oil, and the product is distilled with a solution of ten grams of tartaric acid in 1500 grams of water. After cooling, the residue in the retort, precipitated with ammonia, gives pure brucine.

Cantharidin.—500 grams of powdered cantharides are placed in a displacement apparatus, and are treated repeatedly with two litres of the heavier coal oil, previously heated in a flat-bottomed matrass to boiling by means of a water-bath. The liquor passes of a greenish-brown colour, and when it ceases to run the receiver is changed and the coal oil remaining in the powder is displaced with water. The two products are mixed, filtered, and distilled in a sand-bath until only about 80 grams of liquid remain in the retort. This is thrown into a porcelain capsule, and after about twenty-four hours it forms a greenish mass, in the midst of which appear brilliant needles of cantharidin. It is washed on a filter with a small quantity of carbon bisulphide, which carries off all the fatty matters and leaves the cantharidin intact in fine long silky white needles. Exposure to the air for a few hours removes all traces of the odour.

The yield of cantharidin varies with cantharides from different sources and of different ages; 500 grams of commercial cantharides, origin unknown, gave by this process 2 grams of cantharidin, and some excellent cantharides collected by the authors in the Department of Loiret, gave 5 grams of cantharidin to the kilogram. Fearing that the fatty and colouring matters were an obstacle to the solubility of the cantharidin, the authors exhausted 500 grams of the Loiret cantharides with carbon bisulphide until the decoloration of the liquor. These cantharides, treated as above, yielded at once the same proportion of white cantharidin as before—2·50 grams.

Quinine.—The authors state that a pure and excellent product may be obtained by operating in the following manner:—A decoction is made by boiling, during one or two hours, 1000 grams of yellow cinchona bark (of about 3 per cent.) in 6 litres of water containing 60 grams of hydrochloric acid. This decoction is poured off and two other decoctions are made by boiling the marc during an hour with two successive quantities of 4 litres of water and 30 grams of acid. The product of the three decoctions is treated with a sufficiency of milk of lime; the precipitate, weighing about 150 grams, is dried with care. This is heated in a water-bath with sufficient coal oil to obtain 500 grams of solution, which is distilled with a solution of 30 grams of tartaric acid in a litre of distilled water until about a litre, which contains all the coal oil, has passed over. The residue is filtered, the liquor passing through almost colourless, and measuring about half a litre. Ammonia is then added in slight excess, when there is formed a white curdy precipitate of quinine. 250 grams of benzol are poured in, and the whole heated in a water-bath, stirring from time to time. The benzol is decanted and evaporated in a retort until reduced to one half; this liquor, left to itself, deposits after a few days voluminous crystals of quinine, which effloresce rapidly in the air. When it is wished to obtain the quinine in powder, the precipitation is attended with some difficulty, as the alkaloid nearly always forms a pitchy mass, the desiccation of which is difficult. This may be avoided by pouring the acid solution of quinine, a little at a time, into a mixture of 50 grams of ammonia and 250 grams of distilled water, with slight stirring.

Cinchonine.—Operate as for quinine with one kilogram of grey huanuco bark, 14 litres of distilled water, and 120 grams of hydrochloric acid. Treat the calcareous precipitate with boiling coal oil to remove the small quantity of quinine that it contains. Displace afterwards with a sufficient quantity of carbolized coal oil to obtain 500 grams of tincture, which is to be distilled in a retort with a solution of 30 grams of tartaric acid in a litre of water. The coal oil and carbolic acid pass over entirely, and there remains in the retort a nearly colourless solution of tartrate of cinchonine, surmounted by a layer of resinous matter. After cooling it is filtered, and finally precipitated with ammonia, observing the same precautions as indicated for quinine. The cinchonine thus obtained is completely white.

Narcotine.—Narcotine and codeine are the only opium alkaloids which are soluble in coal oil. To prepare narcotine, 500 grams of the opium residue left in the preparation of the extract are macerated during twenty-four hours in 4 litres of water acidulated with 25 grams of hydrochloric acid. The product is passed through a strainer and the liquor is precipitated with a slight excess of ammonia. The precipitate is washed and dried and then treated, at the heat of a water-bath, with 250 grams of coal oil. The solution filtered whilst hot deposits the narcotine upon cooling, and a second crystallization yields it perfectly white.

The deposit given by extract of opium when treated with cold water contains a large quantity of narcotine, as much as 60 per cent. By treating this deposit with boiling benzine, a large quantity of pure narcotine may be at once obtained.

Aconitine.—Aconite root, coarsely powdered, is exhausted in a displacement apparatus with boiling water containing 1 per cent. by weight of tartaric acid. The product is evaporated to the consistence of a thick syrup and rendered strongly alkaline with caustic soda. After cooling, the mixture is poured a little at a time into benzol, as directed for atropine; the benzol, shaken with a little water acidulated with tartaric acid, yields to the latter the aconitine which is then precipitated by ammonia. Washed and dried, it presents the form of a white powder.

Coumarine is found in considerable quantity in the tonka bean, principally on the surface. In order to obtain it, it is only necessary to wash the whole beans placed in a funnel with cold benzine, and to concentrate the liquor. The coumarine is deposited in voluminous white crystals.

MODE OF MAKING AN EMULSION.*

BY DR. E. SAUNDERS.

A few hints on the above subject may not be unacceptable to some unfortunate who has not had the privilege of being taught this important branch of our art thoroughly. The first thing to do is to see that the mucilage is fresh and sweet; for although good emulsions can be made with sour mucilage, they require more labour, and spoil more quickly. A broad, flat pestle will be found to serve better than a narrow, round-faced one. Be sure that the mortar is clean and free from grease. Then put in the mortar, first, a small quantity of the mucilage and rub it round the mortar, so as to prevent any of the oil from adhering to the side. Add a little of the oil—about half the quantity of oil that you have used mucilage—and rub from the centre; the emulsion will begin to form immediately. When the first quantities are thoroughly emulsified, add first more mucilage and again half the quantity of oil, and make into a perfect emulsion. Continue in this way until the oil is emulsified, adding water between each addition of oil after the right quantity of mucilage has been added. Great care must be taken to keep the mucilage and water in excess of the oil used, or a thick mass will be formed, which it will be impossible to mix with water.

The object in making an emulsion is to have the particles of oil separated by water, but if the oil is in excess, the opposite is liable to take place; the particles of water are separated by the oil, and it is then impossible to form a good mixture, and the shortest way to do will be to throw out the mass and start again with fresh materials. Some people are in the habit of mixing the oil with powdered gum arabic, but it is impossible in that way to obtain a permanent emulsion, or even one in which the oil is sufficiently divided as to render the globules of oil invisible to the naked eye. A still worse mode is to put the oil and mucilage together in a bottle and shake them.

A perfect emulsion should be as white as milk, if made with olive oil, or any light colourless oil; it should mix readily with water in any proportion, without showing any signs of separating on standing, and should leave the mortar, or any vessel it may be put in, in such a condition that simple rinsing with cold water will clean the vessel, without leaving any traces of oil having been in it. The amount of mucilage to be used to a given quantity of oil varies. Half an ounce of mucilage is sufficient for two ounces of castor-oil or balsam of copaiba. Oil of turpentine, and the other light volatile oils, require rather more mucilage and longer trituration. If any syrup or sugar be ordered, it should be added after diluting the emulsion with all the water allowable. The same precaution should be taken with tinctures or any alcoholic preparations. The fact that mucilage of acacia is precipitated by alcohol should always be borne in mind. It is difficult to give an unvarying rule as to the amount of tinctures admissible in one emulsion, as the amount of gum and oil varies so much, but as a rule it is unsafe to put more than one ounce of a tincture made with dilute alcohol in a four-ounce emulsion, and tinctures made with stronger alcohol in proportion. Emulsions, if well made, are very handsome mixtures, and very permanent. The writer has some emulsions of castor-oil made four weeks ago, and of balsam copaiba made three weeks ago, both of which are as fresh and nice as the day they were made, and neither of which shows the least sign of separation.

THE CULTIVATION OF OPIUM AND CINCHONAS IN INDIA.

A great deal of valuable information on the products of India is contained in a recent report on the progress and condition of our Eastern Empire. The importance of opium as a source of revenue has long been an acknowledged fact. Cinchona barks, on the other hand, have, until a comparatively recent period, been only an experiment, though at the present time the cultivation of these trees has got far beyond this stage. So much has been said by different writers on the culture, preparation, and value of opium that it would seem as if nothing more could be said; nevertheless, there are many interesting facts contained in this report which are worth a wider diffusion than that usually accorded to a Government blue-book. The gross revenue upon Bengal opium for the year 1872-73 amounted to £6,069,793. The number of chests sold in that year was 42,675. Government exercises a strict supervision over the poppy cultivation, no one being allowed to grow the plant except on Government account, and the manufacture is conducted at two separate agencies, Patna for Bahar, and Ghazepoor for the North-west Provinces and Oudh. For the Bahar agency 330,925 acres are under poppy cultivation, and 229,430 for Benares. The poppy requires a high state of cultivation, the land has to be specially attended to and carefully manured; nevertheless, of late years the plants have suffered from blight. For the purpose of observing the conditions of this blight, Mr. Scott the curator of the Calcutta Botanic Garden, was deputed, soon after its outbreak, to proceed to the localities where it had appeared, "to work two seed gardens of his own, and watch the blight through all its phases, and he has also under his charge several small experimental gardens at the sub-agencies. Successful trials have been made of the effect of interchanges of seeds between the sister agencies of Bahar and Benares; but the trials of Persian and Malwa seeds have resulted in failure."

With regard to Malwa opium, which is free grown, and has consequently a heavy duty imposed upon it to bring it on an equality with the produce of Bahar and Benares, it is stated that the quantity exported from Bombay, which is its sole legal port of export, amounted during the official year 1872-73 to 42,401 chests.

Turning to cinchona we find a good deal of matter already familiar to us; but when we remember that it is only within the last fifteen years that the cinchona plants have been known at all in India it is surprising to see the facts of their numbers and distribution as here recorded, and the facts are more surprising when we consider that the plants had never before been in a state of cultivation. It was an experiment in the truest sense of the word; the result, however, has been highly satisfactory, and the total expenditure it is stated "has been under £70,000." In the Government plantations on the Neilgherries alone there are at the present time some 2,645,373 plants, covering an area of 950 acres. A private plantation at Balmadies, consisting in 1866, when it was first formed, of 31 acres, was extended in 1868 to 60 acres, and has now a fine crop of splendid trees. A large crop of fine bark was procured from them last year, which was sent to London, and realised good prices. Two other plantations, covering together some 1,000 acres, are reported as being in a thriving condition, besides which are many other smaller ones, in all of which the plants are thriving. At Mercara, in Coorg, there is a small plantation which is about to be extended, and on the Barbabudin hills, in Mysore, there is another plantation containing 24,000 trees. At the well-known plantations at Rungbee, 2,000 acres are under cinchona cultivation. Bark from this plantation has been seen in the London market, and has realised prices ranging to 1*s*. 3*d*. per lb. Besides these various plantations the cinchonas have also been taken into British Burmah, and planted at an elevation of about 3,700 feet above the sea; in one plantation between 300 and 400 plants are now fairly established. The well-known trees are said to "cover the slopes of the mountains which overhang Wynaad, and line the hillsides almost to the peak of Dodabetta. The tallest t ree is now 36 feet high, and 28 inches round the stem. The amount of green bark supplied to the quinine manufactory on the plantations during 1873 was 91,773 lbs., from which Mr. Broughton, the quinologist, manufactures a febrifuge alkaloid at 1½ rupees per ounce, which is supplied to the medical stores. Thousands of fever patients are thus annually cured. In November, 1873, the sale of 25,000 lbs. of Neilgherry cinchona bark belonging to the Government took place in the London market, and realized £3,490, the average price secured being 2*s.* 10*d.* per lb.; while one parcel was sold at the very unusual price of 5*s.* 9*d.* per lb. If this average is applied to the 91,773 lbs. used in the manufactory in India, it will place its value at £13,000. This makes the annual income of the plantations about £16,500, which will increase in future years."

Mr. Wood, who it will be remembered was appointed to the post of quinologist in 1873, has, it is stated, already manufactured a cheap form of the alkaloid, taking his supply of alkali from the ashes of the *Artemisia*, which grows in abundance on the Sikkim mountains, and is very rich in potash. The great problem to solve is said to be the discovery of "the cheapest form in which an efficient febrifuge can be manufactured from the bark; and there is every reason to expect that valuable results may be announced from Mr. Wood's labours."

THE OCCURRENCE OF ORGANIC FORMS IN CONNECTION WITH CONTAGIOUS AND INFECTIVE DISEASES.*

BY J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

Lecture I.

The subject of the present lecture is the relation of bacteria to the chemical and physical processes which constitute the life of the higher animals.

One of the first questions which suggests itself to the mind in approaching the subject is this: How does it happen that these bacteria, which we suppose must have existed half-a-dozen years ago in as great numbers as at present, were then scarcely heard of, and that they now occupy so large a place in the medical literature of this country and of Germany, and have lately afforded material for lively discussion in the French Academy? To us in England the subject is chiefly associated with the truly scientific investigations of Lister—the first to show its practical bearing on the pathology of traumatic diseases. In Germany, there can be no doubt that the extensive inquiry which is now being carried on by so many persons, took its start from the laborious researches of a poor professor of botany at Jena, who, with defective resources, bad instruments, and in spite of discouragement and disparagement of all kinds, has persisted for many years in his strivings to work out this intricate question. Unfortunately, he lost his way at an early stage of his enterprise, and, like many pioneers in exploration, has accumulated results of which it must be admitted that the value is scarcely proportional to the quantity. Need we be surprised that, of the many who are quite ready to sneer at Hallier and his cholera-fungus, few, if any, have undergone the labour of reading his papers?

As introductory to my subject, I must first give a short account of the natural history of the organic forms which we now, following high botanical authority, group together under the term bacteria. Secondly, I shall consider the question of their general influence on the processes of life of the higher animals, and the mode in which this is exercised. This will prepare us for discussing the question how far they act as morbific poisons, or as the vehicles of such poisons, or are characteristic of specific diseases. I would remind you that the question we have before us is not that of the origin of bacteria, nor that of their place in nature, but the more restricted one of their influence on ourselves, and on the lower animals whose life, whose health, and whose diseases are but the counterparts of our own.

It is because they are constantly invading our bodies and attacking the living protoplasm by which the work of life is carried on in our tissues, that we, as pathologists, take an interest in their natural history. It is for this reason that questions relating to them, which at first sight seem recondite and remote, have a direct and immediate bearing on practical questions. For if, as I shall endeavour to show, they are constantly present to us—constantly mixing up their life with ours—we cannot wisely remain ignorant of their nature. We do not aspire or profess to be botanists; but, if plant-forms and plant-life associate themselves with the very processes which it is our business to study, we must become botanists for the occasion.

In the short introductory account I shall give of the forms of bacteria, I shall follow Professor Cohn (*Ueber Bacterien, die kleinsten lebenden Wesen*, Berlin, 1872), as being the only botanist of high authority who has given special attention to the subject. For the remainder of what I intend to say, I am myself answerable. I shall, however, make it my endeavour not to vindicate the views which I have advanced myself, or which others may have attributed to me; but to place before you a general view of the work that has been done during the four years which have elapsed since the subject began to occupy the serious attention of pathologists.

Morphology and Natural History of Bacteria.

The first fact that I shall advance with respect to bacteria is, that they are the smallest and least organized of all living beings. As regards size, it is best to judge by comparison with objects with which we are microscopically familiar. The most common rod-like forms are in length about one-third of the width of a blood-corpuscle; *i.e.*, about $\frac{1}{10000}$th of an inch—so small that, if we examine a liquid containing them, with the ordinary magnifying powers used for histological observations, we can scarcely be said to see them to any practical purpose. It is necessary to have recourse to the best microscopes and the highest powers, if it be desired to observe them in such a way as to arrive at useful results.

What ground have we for stating that they are the lowest organisms? One is, that they present only very slight differentiation of parts; but in this sense they are certainly not simpler than many other forms that might be referred to. The chief ground for the statement lies in this, that they are much less *specific* in their characters—much more under the influence of the conditions under which they originate and are developed—than organisms of any other class. Just as in the higher animals and in man himself we call those functions lowest which are most completely automatic—*i.e.*, most completely under the guidance of known conditions—so also, as regards form, we recognize that while all animal and vegetable forms, even the highest, are moulded by circumstances to fit their places in the economy of nature, this moulding power—this adaptation of form to circumstance—becomes more and more obvious the lower we descend in the scale of development.

The new fact relates to the *habitat* of bacteria—to the medium in which they live—water. They inhabit water either as such in the ordinary sense, or in the various conditions recognized as *moisture*, whether occurring on damp surfaces or as filling the interstices of solid bodies, which bodies, when so impregnated with water, are said to be damp. Those who are familiar with chemical work, know that this quality of dampness goes a great deal further than the popular notion of it; that many things

* Lecture delivered at Owens College, Manchester; reprinted from the *British Medical Journal.*

ordinarily called dry, yield, when subjected to the drying processes commonly used in the laboratory, evidences of being really moist. Consequently, moisture, regarded as a limiting condition of bacterial life, is a very wide and comprehensive one.

From this statement, it must not be understood that bacteria do not exist in the atmosphere. But their existence there in an active form strictly depends on moisture. They attach themselves, without doubt, to those minute particles which, scarcely visible in ordinary light, appear as motes in the sunbeam, or in the beam of the electric lamp. It is by the agency of these particles that they are conveyed from place to place.

Notwithstanding that the word bacterium means a rod, and that many of the forms to be immediately referred to are not rod-like, I am obliged to use it, because it is used by others as a general term for the whole group of organisms known to botanists as *Schizomycetes*. This designation being obviously too long, I attempted, in 1870, to introduce the word *microzymes*, a word which was intended to denote the fact that, in the development of these organisms, the process of vegetation is always associated with chemical processes of a peculiar kind, in a way comparable to that in which the vegetation of the yeast-plant is associated with the alcoholic fermentation. I forego the use of the word microzyme for the reason I have mentioned, viz., that it has not been taken to, but I am not the less sensible that such a word is as much needed now as ever; for it is evidently inconvenient to say, as I now find myself compelled to say, that bacteria —rods—may be either globular, egg-shaped, or filamentous. Cohn classifies our organisms under terms expressive of these various forms, the most important being micrococcus, bacterium, vibrio, and spirillum.

Bacteria have, as a rule, two states of existence—a state of activity and a state of rest. When a liquid teeming with bacteria in the active state is observed under the microscope, the attention is so riveted, that it is an effort to take away the eye from the instrument. The movements have been often described. In the case of rod-shaped bacteria, the axial movement in which the rod advances or retreats in the line of its axis, the direction being frequently reversed, is the most common. This kind of locomotion occurs often by fits and starts, the body remaining in the intervals quite still, or assuming a pirouetting or spinning movement. In all rod-like bacteria, it is probable that the progressive or axial movement is associated with rotation, for, in observing the motion of vibrios, it is easy to see that they, in progressing, twist round the axis of the spiral. When this is the case, it looks as if the filament were executing a wriggling motion, *i. e.*, as if its body were contractile; but this is obviously deceptive. The mechanism of the motion is as little understood as those of *Oscillatoria*, which it closely resembles. It must be carefully distinguished from the passive motions which are exhibited by all particles of size comparable to that of bacteria, when suspended in a liquid of which the density does not differ very widely from their own. We shall find afterwards that certain forms of bacteria appear to be motionless in all stages of their existence.

Rod-bacteria multiply by repeated bisection. This mode of multiplication goes on continuously, the rate varying with the conditions of life, and particularly with temperature. Under favourable circumstances, it is enormous. From actual measurement of the time which elapses in a single case between a bisection and the division of each half into quarters (in other words, of the longest time that a single bacterium remains without dividing), it has been ascertained that the interval in question, in common bacteria, is about an hour. This being the case, it is easy to compute that every single bacterium must produce 16,777,220 individuals in twenty-four hours. Putting it otherwise, the progeny of a mass of bacteria weighing $\frac{1}{2400}$ grain would, at the end of a day, weigh a pound.

In the largest forms of bacteria, it can be made out that each individual consists, not, like an animal cell, of one sort of living substance,* but, like a plant-cell, of a protoplasmic interior enclosed in an envelope of cellulose, by virtue of which the bodies of bacteria are enabled to resist the action of reagents, particularly weak acids and alkalies, which dissolve protoplasm. In those bacteria which separate from each other as soon as they assume the form of distinct individuals, the more stable external part presents itself as a mere envelope; but when, as very usually happens, the progeny which results from a continuous succession of divisions remains in a state of aggregation, the envelope appears to become identified with the "gelatinous" matrix by which they are held together. This observation was made more than twenty years ago by Cohn, who devised the term zoogloea as a general designation for the clumps, or as Hallier calls them from the mode of aggregation above described, "colonies." You will find that this term is now very constantly used by writers on the subject, for these gelatinous masses occur under a great variety of circumstances. In form, they are mostly either spheroidal or membranous, and have this one characteristic which is noteworthy, that their structure is such as to indicate that they grow at their surfaces or margins, not interstitially. Thus, for example, in the spheroidal forms, which, as seen under the microscope, present a more or less circular outline, it is obvious that the multiplication of individuals is most active near the edge. The membranous forms, on the other hand, often present a growing outline in one direction, a disintegrating one in the other.

We are not able to state that the process of repeated division into two is the only one by which bacteria come into existence. When we watch a liquid in which they are beginning to appear as if spontaneously, where none were visible a few minutes before, all that we can make out is, that a nebula presents itself; and that here and there, in the previously homogeneous liquid, particles exist which, although their form is at first indistinguishable, eventually become recognizable as bacteria. As to the way in which this happens, it is difficult to speak positively, for with reference to it no evidence is admissible excepting such as is founded on direct observation—*i.e., on watching the process in a single instance for many hours*—fixing the eye on a single bacterium, a thing weighing two-billionths of a grain, and measuring one-eight-thousandth of an inch, and not quitting it till it divides and divides again. Klebs has attempted to do this, but I will not detain you with an account of his researches.

From what I have said as to their structure and ordinary mode of multiplication by division, it is obvious that bacteria resemble plants, and particularly the Oscillatoriæ, more than animals. The proof that they are plants rests on what is known as the nature of the chemical processes which constitute their life, to the consideration of which we must now pass.

How do bacteria act on the medium in which they live? On this subject, we owe the foundations of our knowledge to Pasteur. The first fact is, that bacteria act on the media in which they live, not as animals, but as plants. Like plants, they derive the nitrogen that they use to build up new albuminous compounds, not from previously existing albuminous compounds, but from ammonia. Like other colourless plants, they derive their carbon apparently from any carbon-compound except carbonic acid, by dissociation of its elements. Like plants, they require certain inorganic constituents to be present in their soil, particularly potash and phosphoric acid.

As regards the assimilation (or fixation), of carbon,

* In using the expression, "one sort of living substance," I must guard against being supposed to mean that any kind of living protoplasm is homogeneous. Strange though it may appear, we are not able at present to assign any limit to its complexity of structure.

Cohn's researches have very materially advanced our knowledge since the publication of Pasteur's work. It was obvious that bacteria did not decompose carbonic acid under the influence of sunlight, by the same wonderful process by which that dissociation is performed by green plants. This they could not do in the absence of chlorophyll. But in this respect they were not in any different position from the fungi, or even from the colourless phanerogamic parasites—as, for example, the bird's-nest orchis.

Pasteur's investigations* related, not to bacteria or to the organic forms which are associated with the process of putrefaction, but to the yeast-plant. With reference to that organism, he proved that it derives its nitrogen directly from ammonia. He proved at the same time that the cellulose of which the external part of the yeast-cell consists, is derived from grape-sugar, and cannot be formed in the absence of that body. He did not extend the application of these facts to the organisms of putrefaction; but it came to be assumed that what was true of the yeast-plant would also be true of the others—viz., that although ammonia was a sufficient source of nitrogen, some hydrocarbon must be present to yield carbon.

Cohn showed this assumption to be a mistaken one, by applying to the organisms of putrefying liquids the same mode of investigation that Pasteur had before applied to the yeast-plant (Cohn, *Beitrage zur Biologie der Pflanzen*, Heft ii, pp. 191-202). That method (since known as the method of cultivation) consists in first finding a liquid of known chemical composition in which the plant to be investigated grows vigorously, and then gradually modifying the composition of this liquid by the elimination of one after another of its ingredients, until at last a mixture is obtained in which the greatest possible simplicity is combined with the greatest possible adaptedness as a soil to the requirements of the particular organism; adaptedness being judged of by rapidity of growth. Such a liquid, as regards the yeast-plant, is that known as Pasteur's cultivating fluid. Its composition stands for the fact that sugar and certain crystalline salts are all that is wanted for the nutrition of the yeast-plant.

In the earlier experiments as to the cultivation of bacteria, *e.g.*, in those which I made in 1871, it was assumed that Pasteur's liquid would also be the most suitable liquid for bacteria. During the same year, however, Cohn, observing that, although bacteria flourished in it abundantly, it was very difficult to prevent the growth at the same time of the yeast-fungus and of pencillium, *i.e.*, common mould, left out the sugar, and found that the bacteria flourished better without it than with it. His next step was to substitute for the solution of yeast-ash (a material which is troublesome to prepare) a solution containing the required salts in about the proportion in which they are ascertained to exist in the ash of the yeast-plant. The liquid which we now use as a "cultivation liquid" for bacteria is prepared by dissolving half a percentage each of potassic phosphate and magnesic sulphate in water having a trace of calcic phosphate in suspension,† and then adding as required a further percentage of ammonic tartrate, and of course boiling the mixture. In this liquid, bacteria grow rapidly—a fact which proves not only that they are able to take their nitrogen from ammonia, but that they can also derive carbon from the tartrate—the only carbon-containing body which is present. Although, however, it supports the life of bacteria so completely, that they not only subsist in it, but multiply with enormous rapidity under favourable conditions of temperature, it never originates them, if it have been boiled. It can, indeed, be very easily kept for indefinite periods without change, remaining absolutely transparent and barren, provided that care be taken to protect it from contamination. It is, however, much better practically to keep the solution of inorganic salts, adding the tartrate in the proper proportion for each set of experiments.

In order to determine the development of bacteria in a liquid of this kind, all that is necessary is to touch it with a "damp" surface—a glass rod, a thread of cotton or silk —*any object which, having been exposed to the atmosphere, has not since its exposure been dried by heating it to a sufficient temperature.* The result may be equally well attained by allowing a particle of dust or a drop of water, or common distilled water, to fall into the liquid. All these liquids, although they contain no organic forms which can be recognized even with the aid of the highest powers, yet contain that which, when added to solution of ammonic tartrate, determines its decomposition, and the building up of its nitrogen and carbon into higher combinations—in a word, vegetation. I call this process quasi-spontaneous. It is not spontaneous, for this simple reason—that it is dependent on conditions which are so far known, that it is possible to control them with perfect certainty.

I may add, that it was by experiments such as those to which I have just been referring that I was enabled to show, in 1871, that moist surfaces and particles of solid material in suspension in the air play the chief part in the propagation of bacteria; *i.e.*, in the conveyance of the material out of which they spring from one soil to another. This inference has now been confirmed—I think I may venture to say, established—by very numerous observations.*

(*To be continued.*)

* The experiments in question are to be found in Pasteur's well-known papers on Alcoholic Fermentation (*Annales de Chimie et de Physique*, tome lviii., 1858).

† The calcic phosphate is best prepared by precipitating solution of calcic chloride with common sodic phosphate, taking care that the former shall be in excess. This precipitate splits on boiling into a soluble and an insoluble phosphate.

* On this subject, see Cohn, *loc. cit.*, p. 194; Landau, *Arch. für Chirurgie*, xvii., p. 531.

RIVERS POLLUTION COMMISSION.

(*Concluded from page* 645.)

Pollution of Water by dissolved Matters.—The analyses of the very numerous samples of foul waters from mines, the results of which are given in the descriptive section of this report, show that the polluting matters present in the effluent water from metalliferous mines are, with very few exceptions, altogether in suspension. The same is the case with the effluent water from clay pits, and it is only to the water discharged from collieries, and from mines upon which arsenic is manufactured, that remedies applicable to polluting matters in solution are required. And of twenty-five samples of water discharged from collieries and coal-washing floors only nine have transgressed any of the suggested standards relating to polluting matters in solution. Of these there were eight transgressions of the standard relating to metals other than calcium, magnesium, potassium, and sodium, the offending metal being iron in each case, and one transgression of the standard relating to arsenic. Taking into consideration the great extent of river channel inspected and the great abundance of collieries in this country, the Commission is of opinion that the sum total of pollution arising from matters in solution derived from coal mines is insignificant. Moreover, the polluting matters when mixed with a considerable volume of river water are not, so far as ascertained, injurious to the health of man or air-breathing animals; they are undoubtedly very fatal to fish, but unlike all other forms of pollution, they only exert their pernicious effects upon water-breathing animals in the immediate neighbourhood of the discharges themselves; the onward flow of a river soon restores to it, by the absorption of atmospheric oxygen, its power of supporting fish life. There is, indeed, a most perfect and efficient remedy for this evil, but this, it is admitted by the Commissioners, will be found considerably more costly than any yet recommended. It consists in adding to the polluted water flowing from the mine, or being discharged from it, a quantity of quicklime (previously slaked), sufficient either to neutralize the acidity of the water, or to replace the oxide of iron it contains. About twelve hours' subsidence of the precipitated oxide of iron would then be required.

The Commission considers that the advantages to be gained by the prevention of this comparatively unimportant form of pollution would not be worth the cost of the remedy.

The only other polluting agent in solution in colliery water is arsenic, which occurred in a proportion exceeding the suggested standard (·05 part metallic arsenic in 100,000 parts of water) only in the case of the water which had been used for coal washing at a colliery connected with the Dowlais iron works near Methyr Tydfil. The occurrence of arsenic in colliery water in so large a proportion appears to be quite exceptional, and as there are no known practical means of removing this ingredient from water, especially if the latter be, like that discharged from the Dowlais coal-washing floor, non-ferruginous, the Commission recommends that colliery water and mine waters generally be exempted from the operation of standards (*d*) and (*e*). This exemption is to some extent justified by the circumstance that these polluting substances are not, as a rule, in the cases exempted, the result of waste products of a manufacturing operation; they are, on the contrary, the result of the natural washing, for the most part unavoidable, of natural mineral substances. It is, however, far otherwise in the case of mines where arsenic is actually manufactured. The vast quantities of white arsenic now being made and sold at the Devon Great Consols and some other mines has been alluded to. This arsenic is required in several important branches of British industry. It is used largely, for instance, in the manufacture of some of the new colouring matters obtained from coal-tar, in calico-printing and dyeing, and in the manufacture of glass and of shot. Whilst it would, therefore, be very undesirable to impose any serious impediments in the way of its production, it appears to the Commission only reasonable that (as is now the case with the retail sale of this article) the manufacture of a poison so virulent that a single ounce of it is sufficient to destroy the lives of 100 men, should be subject to special State supervision; and it, therefore, recommends that any officer appointed for such supervision should be empowered to require that the best practicable means be taken not only to prevent the poisoning of the air by the volatilization of the arsenic, but also to hinder the access of the poison to running water.

Pollution arising from Metal Manufactures.—The remedies for river pollution arising from metal manufactures, are most of them of a very obvious and simple character. The metalliferous liquors discharged from tin-plate and galvanizing works, together with those sometimes allowed to escape in much smaller quantities from brass foundries, German-silver works, and electro-plate factories, contain metallic salts, which, in all well-regulated works, are manufactured into marketable products and sold; or they are sometimes disposed of in their crude condition to chemical mannfacturers who utilize them for various purposes. At Messrs. Thompson, Morgan, and Company's tin-plate works at Broadwaters, near Kidderminster, the waste pickling liquor is concentrated in shallow leaden evaporating pans, until, on cooling, it deposits a copious crop of crystâls of green copperas which is sold at a small profit; the mother liquor from these crystals is fortified with fresh sulphuric acid and used over again, none being allowed to go into the river. In this way all the sulphuric acid used in tin-plate and galvanizing works would become transformed into marketable green copperas, yielding a profit to the manufacturer instead of poisoning the fish in the rivers or destroying the brickwork of the sewers, into which it is now in many cases discharged, in utter disregard of injury to the property of others. The remedy for river pollution from the muriate of iron produced in such works is equally simple, but does not hold out so certain a hope of profit. The crude waste liquor may be concentrated by evaporation and sold as a disinfectant, for which purpose it is valuable; or it may be decomposed by lime or a mixture of chalk and lime, which would transform the polluting muriate of iron into non-polluting muriate of lime; the oxide of iron precipitated by the lime may be sold to iron smelters or gas manufacturers, or dried in the ash-pits of the numerous furnaces employed in such works and then carted away with the ashes. The prohibition of the discharge of metalliferous liquids from tin-plate and galvanizing works into rivers and town sewers, would inflict no serious hardship upon manufacturers; whilst it would preserve much valuable property which is now injured or destroyed by these noxious chemicals. Still less hardship would result from the similar prohibition of such discharges from nickel, iron and steel wire, German-silver, and electro-plate works, and from brass foundries, because the liquids are of comparatively much smaller volume, whilst the metallic salts, which may be extracted from many of them, are of far higher value than those obtainable from tin-plate and galvanizing works. Where the nickel, German-silver, electro-plate and brass factories are situated in towns, such waste liquids as their owners choose to discharge may be, owing to their comparatively small quantity, safely admitted into town sewers. They will not, for the same reason, interfere with the subsequent utilization or purification of the sewage.

The Commission concludes its report by recommending, with the exceptions already mentioned in reference to the standards (*d*) and (*e*), the following liquids be deemed polluting and inadmissible into any stream :—

(*a.*) Any liquid which has not been subjected to perfect rest in subsidence ponds of sufficient size for a period of at least six hours, or which, having been so subjected to subsidence, contains in suspension more than one part by weight of dry organic matter in 100,000 parts by weight of the liquid, or which, not having been so subjected to subsidence, contains in suspension more than three parts by weight of dry mineral matter, or one part by weight of dry organic matter in 100,000 parts by weight of the liquid.

(*b.*) Any liquid containing, in solution, more than two parts by weight of organic carbon, or ·3 part by weight of organic nitrogen in 100,000 parts by weight.

(*c.*) Any liquid which shall exhibit by daylight a distinct colour when a stratum of it one inch deep is placed in a white porcelain or earthenware vessel.

(*d.*) Any liquid which contains, in solution, in 100,000 parts by weight, more than two parts by weight of any metal except calcium, magnesium, potassium, and sodium.

(*e.*) Any liquid which, in 100,000 parts by weight, contains, whether in solution or suspension, in chemical combination or otherwise, more than ·05 part by weight of metallic arsenic.

(*f.*) Any liquid which, after acidification with sulphuric acid, contains, in 100,000 parts by weight, more than one part by weight of free chlorine.

(*g.*) Any liquid which contains, in 100,000 parts by weight, more than one part by weight of sulphur, in the condition either of sulphuretted hydrogen or of a soluble sulphuret.

(*h.*) Any liquid possessing an acidity greater than that which is produced by adding two parts by weight of real muriatic acid to 1,000 parts by weight of distilled water.

(*i.*) Any liquid possessing an alkalinity greater than that produced by adding one part by weight of dry caustic soda to 1,000 parts by weight of distilled water.

(*k.*) Any liquid exhibiting a film of petroleum or hydrocarbon oil upon its surface, or containing, in suspension, in 100,000 parts, more than ·05 part of such oil.

In any enactment for the correction of River Pollution the above standards may be safely qualified by the following proviso:—Provided always, that no effluent water shall be deemed polluting if it be not more contaminated with any of the above-named polluting ingredients than the stream or river into which it is discharged.

The Commission is also of opinion that any law having for its object the prevention of River Pollution should—

(1.) Absolutely forbid* under adequate penalties the casting of solid matters into river channels;

(2.) Enact the foregoing standards of purity† below which any liquid discharges into watercourses should, with the exceptions already mentioned, be forbidden;

(3.) Give power to all manufacturers in towns, except‡ those of gas, paraffin oil, pyroligneous acid, animal charcoal, tin-plate and galvanized iron, to discharge their drainage waters into the town sewers under suitable regulations;

(4.) Confer additional powers on corporations, local boards, manufacturers, and mine owners, to take land compulsorily, under "Provisional Order," for the purpose of storing their waste refuse, or of cleansing sewage or other foul liquids, either by irrigation, filtration, or otherwise.

Further that the equal and efficient administration throughout the country of any Act that may be passed for these purposes would be best secured by the appointment of inspectors to whom should be committed the duty of detecting and proving offences against the law, and of procuring the conviction of offenders, and that in order to secure the independence of these inspectors from local influences they should, like the Inspectors under the Alkali Act, hold their appointments from Government.

SOIRÉE OF THE MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The annual *soirée*, under the presidency of Mr. Thomas Barclay, in connection with this Association, was held in the Town Hall on Thursday evening, Feb. 4th, and was attended by nearly four hundred persons. Hitherto the *soirée* has taken place at the Royal Hotel, but this year the accommodation was found to be insufficient for all who desired to be present. The arrangements for the entertainment of the guests were admirably carried out. The floor of the hall was covered with a diaper cloth, and there were temporary stairs for ascending to the side galleries. Part of the great gallery and the corridors were set apart for the exhibition of a variety of interesting objects, chemical and scientific experiments, and processes of art and manufacture. One of the most interesting experiments in the great gallery was Mr. W. Crookes's discovery of attraction and repulsion by radiation, exhibited by Dr. R. H. Norris. Three glass bulbs were arranged on a small wooden frame, each of them having suspended within it, by a delicate filament of silk, a small bar of pith. One bulb contained atmospheric air, while in the second the air was partially, and in the third entirely exhausted. The object of the experiment was to illustrate the fact that heat and light can produce repulsion in solid bodies when they are delicately suspended. Mr. Crookes in the course of some experiments a short time ago discovered that a bar of pith delicately suspended in a closed glass bulb which contained atmospheric air of the ordinary pressure was attracted towards the source of heat or light; but that when he proceeded to exhaust the air in the bulb, in the process of exhaustion he came upon a *nil* point, or a point of zero, at which there was no attraction. In proceeding still further with the exhaustion he found a further point at which the pith bar became repelled by heat or light. This was illustrated by the application of a spirit lamp to each of the three bulbs. In the first the bar was attracted, in the second there was no attraction, and in the third the bar was repelled. Mr. C. J. Watson exhibited an experiment in thermo-electricity on a table opposite. Dr. Davis's curious experiment illustrating the motion of the waves was exhibited by Mr. C. J. Woodward, B.Sc.

An apparatus called a compound pendulum, by which a variety of most elaborate and intricate designs can be drawn with the greatest precision by the motion of two pendulums, was shown by Mr. W. R. Morris.

The whole of the east corridor was occupied by Messrs. Gammon, Marrian, and Co., the well-known Birmingham confectioners. They had made extensive preparations, and had taken great trouble in order to illustrate to the visitors the many interesting processes in the manufacture of sweetmeats. About a dozen of their workpeople were engaged in making lozenges, liqueurs, creams, and a variety of fancy confectionery. This corridor during the evening, as might be expected, was considerably patronized, especially by the ladies, who were greatly interested in the various processes.

In the west corridor several of Southall, Bros., and Barclay's *employés* carried on two or three important chemical processes known as Sublimation and Scaling. The art of engraving on glass was shown on an adjoining table by Mr. John Tomey (from the works of Messrs. Stone, Fawdry, and Stone). In the same corridor Mr. Willmott, of Great Hampton Row, gave some practical illustrations of paper box making. Several of his workpeople showed the plan of making paper boxes, comprising square, oblong, and other varieties. The exhibition of scientific instruments, chemicals, and other articles remotely and directly connected with the pharmaceutical and chemical profession was of a first-rate character. Mr. J. E. Howard, F.R.S., contributed some fine herbarium specimens, illustrating the genus cinchona. A large number of new and powerful microscopes and microscopic objects, exhibited by local opticians and manufacturers under the management of Mr. Wright Wilson, M.R.C.S., F.L.S., occupied a prominent position on a table, and were a source of instruction and amusement. In the large collections of chemicals, new drugs, etc., Messrs. Hopkin and Williams and Messrs. Morson and Son, of London, were conspicuous exhibitors, as were also Messrs. Southall, Bros., and Barclay, of Birmingham. The other principal objects in the same row which attracted great attention were a large and valuable miscellaneous collection of surgical instruments and novelties, sent by Messrs. Lynch and Co., and Messrs. Maw, Son, and Thompson, London; a lot of very old herbal and botanical works, also a beautiful collection of foreign medicinal plants, bark, flowers and fruits and other botanical specimens which were in excellent preservation, were lent by Mr. W. Southall, F.L.S. Mr. Sunderland, photographer, of Bull Street, showed a large number of photographic views of the principal buildings and churches in Birmingham and the suburbs. At half-past eight o'clock the *soirée* opened with a lecture by Mr. Josiah Pumphrey, who used lime-light illustrations. Dancing commenced at about half-past nine. The *soirée* was a great success, which is to a great extent due to the exertions of Mr. W. Jones, the honorary secretary.

---

* A precedent for this provision exists in the Newport (Monmouthshire) Harbour Act, 32 & 33 Vict. c. 118, s. 18.

† A precedent for the enactment of standards for the definition of forbidden discharges exists in the Alkali Act, 26 & 27 Vict. c. 124.

‡ A precedent forbidding foul discharges into sewers exists in the Metropolis Management Act, 18 & 19 Vict. c. 120, s. 205.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 20, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed " Pharm. Journ."*

PHARMACY AND THE PHARMACOPŒIA.

WHEN MR. SPURGEON reproved the inconsistency of those of whom he said that they bore the loss of thousands with equanimity, and blasphemed furiously over a missing shirt-button, he only illustrated a common paradox in his accustomed vigorous style. We are about to refer to a similar, if less grotesque, example in connection with the pharmaceutical body in this country. An event of paramount importance has passed before our eyes without apparently attracting any special observation, while topics of the most ordinary kind have come in for a full share of criticism. The circumstance to which we allude has such an important bearing upon the honour and dignity—and, as we believe, upon the material advancement—of pharmacy, that we make no apology for placing it more conspicuously before our readers.

In a discussion on the Additions to the British Pharmacopœia, which took place at an evening meeting of the Pharmaceutical Society last May, Mr. CARTEIGHE took occasion to point out the propriety of giving greater prominence to the element of practical pharmacy in the Pharmacopœia Committee of the Medical Council.*

Again at the meeting of the Council of the Pharmaceutical Society,† in the month of July, Mr. HAMPSON, in pursuance of this suggestion, submitted a resolution, which was seconded by Mr. GREENISH, and after discussion and amendment was ultimately carried unanimously in the following terms :—

"Resolved—That this Council respectfully urges "upon the Medical Council the desirability of asso- "ciating more practical pharmacists with any Com- "mittee which may be appointed for the purpose of "preparing any future edition of the British Phar- "macopœia, or any further addendum to the present "issue. This Council would be prepared to nominate "such pharmacists in the event of the Medical Council "agreeing to their proposal."

A copy of this Resolution was officially communicated to the Medical Council and read at its next meeting, but *no answer* was vouchsafed to the suggestion thus respectfully submitted, and we are left to the mortifying conclusion, that the Medical Council declines to consider the representations of the Pharmaceutical Society in reference to a matter in which pharmacists, as well as medical men, are so profoundly interested. But, though this may change the scene, it cannot decide the issue. The reasonable claims of pharmacy cannot be thus summarily disposed of. The Council of the Society is pledged to the principle embodied in the Resolution, and it will be supported in the endeavour to carry that out by the unanimous voice of the body it represents. It cannot go back, it must not stand still, nor can we regard any *permanent settlement* possible which does not give to pharmacy an independent and responsible share in the compilation of the national Pharmacopœia.

The powers of the Medical Council are derived from the Medical Act, 1858, which was passed for the purpose of regulating the qualification of medical practitioners, but the occasion was incidentally used for amalgamating the three Pharmacopœias and placing the new British Pharmacopœia under the direction of a more representative parliament of medical science. This measure, whether so intended or not, was, in effect, an important step towards the admission of pharmacists ; but the Act being essentially a *Medical* Act could not properly include pharmacists in its executive ; nor perhaps had the time arrived when pharmacy could successfully substantiate its claims to share the privileges of the medical corporations. In the sixteen years which have since elapsed much progress has been made in pharmaceutical education, organization and status. The Pharmacy Act, 1868, both recognized the past operations of what till then had been no more than a voluntary Society, and conferred upon it substantial privileges: it restricted the practice of pharmacy, even more stringently than the Medical Act restricts the practice of medicine, to duly qualified registered persons ; and entrusted to the Pharmaceutical Society the duty of testing the qualifications and protecting the register of future pharmacists. If this important recognition had preceded the enactment of the Pharmacopœia clause of the Medical Act the Society would have had a *locus standi* before the Parliamentary Committee on the Bill, and there is every reason to believe that its application must have been successful.

It is not necessary, nor would space permit us, to substantiate the claims which pharmacy can advance to take part in the compilation of the Pharmacopœia. Unless words are a perversion of sense the proposition is itself a truism. The competence of pharmacists and the advantage of the organization of the Pharmaceutical Society for collecting materials for the work are sufficiently attested by the course actually taken for the publication of the last edition. We quote from the preface: "The Council think it right "to add that the present edition of the Pharmacopœia "has been *prepared by* PROFESSOR REDWOOD, *of the* "*Pharmaceutical Society*, and Mr. WARRINGTON, of

* See PHARM. JOURN. [3], vol. iv., pp. 900 *et seq.*

† See *ante*, p. 15.

"Apothecaries' Hall,* under the direction of a Committee of the Council consisting of the following "members: Dr. BURROWS, Dr. APJOHN, Dr. CHRISTISON, Dr. SHARPEY, and Dr. QUAIN, who also "acted as Honorary Secretary."

The practice of almost every other country in Europe, as well as that of the United States of America, constitutes an overwhelming precedent in our favour, to which we may add that it is in harmony with our national theory of Government that those who are bound by the law should be represented in the Councils where the law is made.

We attach much importance to the influence which the desired privilege would exert upon the advancement of pharmacy and the elevation of pharmacists. Nothing could be better calculated to promote pharmaceutical science and to encourage pharmaceutical research than the laudable ambition of contributing to make the national Pharmacopœia a worthy standard of British Pharmacy. It is even more than a national question, and we owe it to the pharmacists of Europe and America that our common vocation should not be dishonoured in our keeping; but we invert the proper order of things when we set ourselves to devise the scheme of a Universal Pharmacopœia, and send delegates to the farther end of Europe to assist in framing a codex for all Christendom, while we sit down ignominiously at home under the imputation of being unworthy to take part in the compilation of our own. There are probably few of our readers who have not at some time or other experienced annoyance at their own superior knowledge being over-ruled by an assumption of *ex cathedrâ* infallibility, and they will appreciate the importance of the principle for which we contend, that it is the province of pharmacy to pronounce authoritatively upon pharmaceutical subjects.

While we regretfully feel that the Medical Council treated the respectful proposition of the Pharmaceutical Society with scant courtesy, we are willing to believe that "all is for the best." It was right to make the overture, but it would not be satisfactory for pharmacists to hold a place on the Pharmacopœia Committee at the pleasure or by the sufferance of the medical element. Both faculties have an inherent title to be represented, and both must be there with co-ordinate powers, derived from a common source. This is the system in operation abroad, and nothing less should satisfy us. We are now driven by the force of circumstances to appeal to a more powerful and impartial tribunal, where our claims will be decided upon their merits; and we trust that the Members of the Pharmaceutical Society will see their way to urging this course upon their representatives, and be prepared at the annual meeting in May next to give to Mr. HAMPSON's later words the weight of an instruction to the incoming Council, viz., "that "the Parliamentary Committee should be alive to "the importance of this question, and that if any "opportunity presents itself, such as an amendment "of the Medical Act, it may be taken advantage "of to bring the subject *under the notice of the* "*Legislature.*"

* In consequence of Mr. Warrington's illness the onus of this duty devolved almost entirely upon Dr. Redwood.—ED. PHARM. JOURN.

THE ADULTERATION OF FOOD AND DRUGS BILL.

THE Adulteration of Food and Drugs Bill which Mr. SCLATER-BOOTH introduced into the House of Commons on Friday last, has been printed, and will be found at p. 675. Mr. SCLATER-BOOTH has reserved for the second reading, which is fixed for the 19th inst., his explanation of the principles of the Bill. Meanwhile it is worth notice that it proposes to repeal the 24th section of the Pharmacy Act, 1868, which refers to the adulteration of medicines. The seventh clause would appear to indicate an intention to give the Pharmaceutical Society a recognized position in the working of the Act. What its particular duties would be are not very clearly stated, although possibly they might consist in assisting to define the limitation of the "usages of trade" referred to more than once in the Bill. We shall be glad to be informed of the opinions of those of our readers who have considered the subject, as to the probable working of the proposed Bill.

THE STUDENTS' ASSOCIATION.

WE are requested to state that at the next meeting of the Students' Association, to be held on Thursday evening, the 25th inst., at 17, Bloomsbury Square, a paper will be read by Mr. JOHN MORRIS BROAD, on "Pharmaceutical Ethics." The attendance of assistants or apprentices as visitors is invited.

THE SALE OF MILK OF SULPHUR.

WE have received a communication from Messrs. HIRST, BROOKE, and HIRST, of Leeds, enclosing a recommendation from the Solicitors engaged in the defence of the recent prosecution that the wholesale druggist should advise his customers not to sell milk of sulphur without attaching a label declaring its mode of preparation. The words suggested are "Milk of Sulphur.—Lac Sulphuris, not Sulphur "Præcipitatum." The proposition is so reasonable and self-evident, that it will probably be adopted by all persons who are likely in this respect to be affected by the operation of the Adulteration Act.

PHARMACY IN IRELAND.

IN reply to a question by Mr. ERRINGTON, Sir MICHAEL HICKS BEACH stated in the House of Commons on the 11th instant, that it is the intention of the Government to bring in a Bill during the present session to regulate the practice of pharmacy in Ireland.

A GRATIFYING testimonial has recently been presented to Mr. F. CUPISS, M.R.C.V.S., of Diss, a founder, and formerly a member of the Council of the Pharmaceutical Society. The occasion was a desire on the part of the townsmen and friends of Mr. CUPISS to show their sympathy with him under the circumstances of the destruction by fire of a valuable house which he had bought and fitted up for the purpose of retiring from business after being engaged in it during more than fifty years. A sum of £101 13*s.* 6*d.* was rapidly subscribed, which was presented privately to Mr. CUPISS by the Rector of the parish and the Secretary for the testimonial.

AT the next meeting of the Quekett Microscopical Club, on Friday next, the 26th inst., a paper on the Histology of the Eye will be read by Mr. B. T. LOWNE, M.R.C.S. etc.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH, EDINBURGH.

The third meeting of the present session, took place in the Society's rooms, 119a, George Street, on Monday evening, 15th February, at half-past eight o'clock.

Mr. William Gilmour, President in the chair.

Mr. John Sadler, lecturer on botany to the Royal High School, and assistant to Professor Balfour, Edinburgh University, made a very interesting communication on—

Edible Mushrooms and Toadstools.

Mr. Sadler began his lecture by pointing out the fact that as there were upwards of 600 genera and 5,000 different species of fungi their presence was universal. Their growth was generally inseparable from and connected with the decay or transition of matter from one state to another. He referred to the extensive diseases caused by the lower forms of fungi amongst plants and animals, and even in the human subject. Amongst the former he instanced the potato, turnip, wheat, and vine diseases, and amongst the latter, the diseases of many insects, the beard disease of man, fevers of several kinds, cholera, etc. In contrast with these evils, he pointed out the great benefits conferred by the fungi acting as "scavengers" in removing the dead and dying matter, by a beautiful process of burning. He referred to the different situations in which fungi were found and explained their structure, mode of growth, and classification. He also dwelt at some length on the mushroom and toadstool form of fungi, and pointed out the difficulty of distinguishing between edible and poisonous species, and related some personal experiences, not of the most pleasant nature. Interesting details were given regarding the principal edible kinds used in Europe at the present time, as well as the effects on the human subject of various poisonous species. The lecture was illustrated by a large series of diagrams, models, and dried specimens.

At the close of Mr. Sadler's paper which was frequently applauded, and after some remarks by Dr. Wm. Craig and others, a hearty vote of thanks to the lecturer, proposed by the president, and seconded by Mr. Young, was carried with acclamation.

The Secretary then announced the following contributions to the library of the Branch:—104 volumes of various works with sundry pamphlets from the Society in London; 'Pharmaceutical Journal,' from Toronto; 'Journal of the Chemical Society,' and library catalogue, from Mr. Mackay; two large volumes of Coloured Medicinal Plants, with two printed volumes descriptive of the same, by Dr. Von Esenbeck, from Mr. Tait, Princes Street, Edinburgh; twelve volumes Gmelin's 'Organic Chemistry,' nicely bound, and in perfect order; six volumes Gmelin's 'Inorganic Chemistry,' with a complete index, bound, and in excellent order; two volumes of the 'Elements of Chemical and Physical Geology,' by Gustav Bischof, also in good order, from Mr. P. R. Brown, Edinburgh.

Mr. Mackay proposed that special votes of thanks be given to those gentlemen who had so handsomely contributed to the library, but more especially to Mr. Brown, whose contributions had of late been so numerous and so valuable.

This motion, seconded by the president, was carried with loud applause.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the members of the above Association was held at the rooms, Halford Street, on Tuesday, the 2nd instant. Mr. Clark, President, in the chair. The following report having been read, was unanimously adopted.

"In directing the attention of the members to the proceedings of the Society during another period of its existence, it gives the Committee great satisfaction to be able to say that, in their opinion, the twelfth session yields to no other, either as to the amount or importance of the work accomplished. Though the number of members has been somewhat smaller than usual, the attendance at the Meetings of the Association has improved in a marked degree, notwithstanding the numerous other classes and lectures in art, literature, and science, held regularly in the town through the winter months.

"The Committee hope that the impetus thus given to the Society may not prove transient, but may indicate a determination on the part of its members to devote themselves more earnestly to the acquisition of that knowledge which, in their opinion, will alone ensure success to the future pharmacist.

"The laboratory, which was fitted up during the previous session, has been used constantly by gentlemen preparing for their examinations, and has been extremely useful in enabling them to obtain that experimental knowledge of the facts and laws of the science of chemistry demanded under the new regulations.

"The museum, which is being arranged under the supervision of two gentlemen appointed by the Committee, has also proved of great service to the members, as a means of acquiring a practical acquaintance with the distinguishing characteristics of the various drugs and chemicals used in medicine, and the Committee take this opportunity of expressing their gratitude to the gentlemen who have so ably fulfilled the onerous duties of curators.

"During the session, two lectures on scientific subjects have been delivered by Mr. J. E. Weatherhead and Mr. F. T. Mott, and forty-one classes have been held, conducted by Messrs. Clark, Cadoux, Wright, and Basker, the average attendance at which has been ten. The Committee feel that they are only giving expression to the general sentiment, when they tender their thanks to those gentlemen who have contributed so much to the success which has attended the past session, by devoting their time, energies, and abilities to the advancement of the Society's interests."

After the usual vote of thanks to the retiring committee and the class teachers, the members proceeded to elect the Committee for the ensuing session, with the following results:—Mr. T. Wright, President; Mr. S. H. Cadoux, Vice-President; Mr. W. B. Clark, Treasurer; Mr. A. W. Shakespeare, Secretary; Mr. E. H. Butler, Mr. E. J. Bishop, Mr. J. M. Duncalf.

The Treasurer's account for the half-year, ending January 31st, was presented showing an income of £20 12*s.* 10*d.*, and an expenditure of £11 12*s.* 3*d.*, leaving a balance in hand of £11 12*s.* 0*d.*

CHEMISTS AND DRUGGISTS' SOCIETY OF IRELAND.

The monthly meeting of this Society was held at the Society's rooms, William Street, Dublin, on Tuesday evening, the 9th inst., Professor Tichborne, V.P., in the chair. After some formal business, the Honorary Secretary, Mr. W. Hayes, informed the meeting that the services of Dr. Frazer had been secured to conduct the botany and materia medica class, which will commence at the end of the present month. He considered the Society fortunate in having secured so eminent a man as their teacher.

Professor Tichborne congratulated the Society on the acceptance of the duties by Dr. Frazer and reminded his audience that, although the botany and materia medica class might not be so interesting as the class in chemistry, on account of the absence of experiments, yet it was fully as important to the pharmacist, and he urged the members not to miss a single lecture.

In reply to a question from Mr. Holmes, the Secretary said he was not able to give the Society any information about the introduction of a Pharmacy Bill for Ireland, but that he had had a conversation on the subject with Mr. Errington, M.P., who would, no doubt, question the Government. In reply to a further question, he said he had received no communication from the Pharmaceutical Society of Great Britain on the subject.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

At the ordinary monthly meeting of this Association, held on Wednesday evening, February 10th, Mr. W. S. Brown, President, in the chair, Mr. Louis Siebold, F.C.S., delivered the fourth of his series of lectures on the

Analysis of Common Articles of Food and Drink.

Mr. Siebold commenced by referring to a statement made in his last lecture, that the amount of solids not fat in milk should not be less than 9·3 per cent. At a recent meeting of public analysts 9 per cent. had been adopted as the standard by which samples should be judged. Passing on to butter, the lecturer said the analysis of this substance was not so simple as that of milk. Some of our public analysts are exceedingly clever; they can not only tell us to what extent butter is adulterated with foreign fats, but can write down the percentage of lard, beef suet, mutton suet, etc., which has been used. He did not profess to be able to do this. It was not, however, very difficult to estimate the proportion of fats other than butter fat which a sample contained, and it was not of much consequence to the public whether the adulterant had been beef, mutton, or other fat. As a preliminary test, a weighed quantity of the butter under examination should be dried on a water-bath and exhausted with cold ether, which would dissolve out the pure butter fat only, and on evaporation in a water-bath should yield not less than 80 per cent of the quantity of butter operated on. Should this experiment prove the necessity of a quantitative analysis, the following process was recommended.

Dry a weighed quantity on a water-bath until its weight remains constant; the loss is water, which in good butter should not exceed five or ten per cent. Then exhaust with hot ether and carefully wash the residue on a filter with more ether; the filtrate will contain the butter fat mixed with any other foreign fats present in the sample, but on cooling the latter will separate, settle down, and may be removed by filtration, and weighed; the butter fat may then be recovered from the ethereal solution and weighed as in the preliminary test. The residue left on the filter from the hot ethereal solution consists of the salt and casein; dissolve out the former by hot water and estimate by solution of nitrate of silver. The casein may then be dried and weighed.

Stoddart's method of estimating the value of butter by the use of Horsley's milk tubes * was then described and strongly recommended.

Flour.—A rough, but very useful test of the quality of this substance, and one that may be very quickly applied by a purchaser to a number of samples, consists in mixing one ounce of each with half an ounce of water. That which makes the stiffest paste is the best. Colour must of course be taken into account, and if the stiffest is also the whitest, so much the better; but it often happens that very white flour contains much water and forms a thin paste when mixed in this way. The quality of flour does not depend entirely on the skill or honesty of the miller, grain grown in southern countries, as Austria and Italy, is richer in gluten than that grown in our own and colder countries.

Mineral matter is now but seldom added to flour to increase its weight. A good sample should not yield more than 1 to 1½ per cent of ash.

Ergot is a very dangerous impurity often present in rye flour. If the sample be treated with solution of caustic potash if ergot be present trimethylamine will be produced and volatized, and may be detected by its herring-like odour; or if the vapours be passed through a heated tube and the products condensed in water, hydrocyanic acid will result from the decomposition of the trimethylamine, and may be detected in the usual manner.

Ergot may also be detected by shaking a sample of the flour with ether, adding a few crystals of oxalic acid, boiling for a short time and then allowing the flour to subside, the supernatant liquid will show a red coloration should ergot be present.

Bread.—The demand for very white and light bread had led to the addition of small quantities of sulphate of copper, or larger quantities of alum, to the flour by the baker, these substances having been found to exercise a remarkable effect in whitening bread.

Copper may be detected by incinerating a sample of the bread, treating the ash with water and dilute nitric acid, concentrating the solution, and treating it with solution of hydrogen sulphide, when any copper present would be thrown down as sulphide, and might be examined in the usual way.

Seven years ago, when experimenting on this subject, the lecturer had been unable to obtain bread free from alum from any baker in Manchester. There had, however, been a great improvement of late. The quantitative estimation of alum in bread is not an easy operation. Not less than 1,000 grains should be incinerated, and this being a very slow process, occupying several hours, a little nitrate of ammonia may be added occasionally to assist the burning out of carbonaceous matter. The ash should then be treated with pure hydrochloric acid and heated to dryness, the residue exhausted with water and more hydrochloric acid, then concentrated, and treated with solution of pure caustic soda in excess, to precipitate the earthy phosphates. The alumina passes into solution, and may be precipitated from the filtrate by boiling with solution of ammonium chloride; from the precipitated alumina, washed, dried, ignited, and weighed, the percentage of alum present in the sample of bread may be calculated.

A simplification of this method by Mr. E. L. Cleaver, which is published in the *Pharmaceutical Journal*, [3] iv. p. 851, was then described and strongly recommended by the lecturer.

Horsley's mode of applying the logwood test is exceedingly simple and sufficiently delicate to detect 1 grain of alum in one pound of bread. A drachm of weak tincture of logwood is mixed with one drachm of strong solution of ammonium carbonate and two ounces of water. A piece of the suspected bread is immersed in this solution for five minutes, removed, drained, and treated for a short time on a water-bath. If pure it will show a delicate pink colour which almost disappears on drying, but if adulterated with alum it will assume a violet colour. This is one of those preliminary tests which any chemist and druggist is capable of performing, and which, if showing the absence of alum, may save the trouble of a tedious quantitative analysis.

Starches.—In the microscopic examination of these, authentic specimens should be used for comparison. In this way the characteristic appearances of the various kinds will be much more easily learnt than from plates. It is important to the pharmacist to have a ready test for distinguishing pure from adulterated arrowroot. If one part by weight be shaken for ten minutes with ten parts of dilute hydrochloric acid (made of equal volumes of the B. P. acid and water), the mixture should not gelatinize, nor develop any odour. Pure arrowroot will subside, leaving the acid perfectly limpid; any other starches used as adulterants will render it more or less gelatinous, and the presence of potato starch will be indicated by a peculiar odour, not unlike that of French beans.

Coffee and Chicory.—Pure roasted coffee leaves about four per cent. of ash, for the most part soluble in water, and containing neither sodium nor silicon. Roasted

* See *Pharmaceutical Journal* [3], vol. v., p. 189.

chicory leaves five per cent. of ash nearly insoluble in water, and containing both sodium and silicon. Roasted coffee contains about one per cent. of sugar; chicory, twelve to eighteen per cent. The sugar may be estimated in infusions by Fehling's copper test, ten c.c. of which indicate half a decigram of sugar. Coffee is much lighter than chicory, and some years ago Mr. Draper proposed a plan of separating one from the other, based on this fact. He stated that by floating one c.c. of the mixture carefully on the surface of water in a tube, the lower and narrower part of which is graduated into tenths of a c.c., the chicory would shortly sink to the bottom of the tube, where its quantity might be read off; whilst the coffee would remain suspended. This test is of little value, as specimens of coffee are met with which will sink very rapidly, and of chicory, which will remain long suspended. The colour of their respective infusions is of much more importance: cold water will take up colour from chicory almost instantaneously, but remain colourless for some time when mixed with pure coffee. The test is best applied by shaking fifteen grains with four ounces of water.

The absence of sodium in the ash of pure coffee affords another ready means for the detection of chicory. Neither coffee nor chicory contains starch. If, therefore, a sample shaken for a few minutes with liquor potassæ should yield a filtrate which, when acidulated with hydrochloric acid, gives a blue coloration with tincture of iodine, it has been adulterated with roasted grain.

The analysis of tea will form the subject of Mr. Siebold's next lecture, to be delivered on Wednesday evening, March 10th.

LEEDS CHEMISTS' ASSOCIATION.

The seventh meeting of this Association, session 1874-5, was held in the library, on Wednesday evening, the 10th inst., the President, Mr. F. Reynolds, in the chair, when Mr. J. R. Kirk was duly elected an associate, and Mr. Joseph Walker proposed as an associate.

The Chairman then called upon Mr. H. Pocklington to read the paper for the evening which was entitled "Sugar Optically and Chemically Considered." This paper will be published in a future number.

On its conclusion an enthusiastic vote of thanks was passed to Mr. Pocklington, on the motion of Mr. Yewdall, seconded by Mr. Childe.

SOCIETY OF ARTS.

ALCOHOL, ITS ACTION AND ITS USES.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

LECTURE III.

(*Continued from page* 655.)

If any of you ever visited the Royal College of Physicians you would find there a system of blood-vessels dissected and traced out by the immortal discoverer of the circulation of the blood himself, William Harvey; and I think it would strike you, as you looked on, that all the organs of the body, which constitute the body in its entirety, are built upon these minutes vessels. It is as though Harvey had suggested the thought that the vascular system was the primary part of the animal organization, and that upon it were planted and developed all the structures. I have here had constructed a diagram illustrative of what I mean. The arteries are all shown branching out into their extreme divisions and giving the outline of the limbs, of the brain, of the visceral parts, and of the other organs. The veins are seen springing or continuing from these extreme arterial parts, as rivers may be said to spring, and to form at last trunks of large and larger size by which they bring back the blood to the centre of the circulation to be vivified there, and carried on again.

From this distribution of blood in these minute vessels the structures of organs derive their constituent parts; through these vessels brain matter, muscle, gland, membrane is given out from the blood by a refined process of selection of material, which up to this time is only so far understood as to enable us to say that it exists.

These minute vessels are therefore more intimately connected than any other part with the construction and with the function of the living matter of which the body is composed. Think you that this mechanism is left uncontrolled? No; the vessels, small as they are, are under distinct control. Infinitely refined in structure, they nevertheless have the power of contraction and dilatation, which power is governed by nervous action of a special kind. If we pass to the lower class of animals, we find, running along the body, in addition to its vascular system, a series of points of nervous matter, consisting of what are called ganglia. These ganglia are connected together in chain, and from them filaments of nerves emanate, which are distributed to all the active moving parts of the body. In the lower animals the nervous system thus described stands alone, and when we rise in the scale and come even to man we find still the same primitive nervous chain. But we find also now another and more highly developed nervous system, the centres of which are locked up in the brain and spinal column, from which centres nerves of special sense go into the organs of sense, nerves of sensibility or common sensation go to the skin and other sensitive surfaces, and nerves of voluntary motion go to the muscles, all combining to perform their respective functions in the animal economy.

Thus man has two nervous systems: the primary nervous chain and the added centres, with their fibres. The two systems are connected by their fibres in different parts, but they are still distinct, both anatomically and functionally. The primary nervous system is called the system of the organic vegetative or animal life; it governs all those motions which are purely involuntary, and its centres are believed by some, and I think with perfect correctness, to be the seats of those faculties which we call emotional and instinctive. The centres of the brain and spinal chord, with their parts, are the centres of the volitional and of the reasoning powers of all those faculties, that is to say, which are directly under the influence of the will.

Keep in mind, if you please, the two nervous systems, and add to the remembrance this one additional fact, that all those minute blood-vessels at the extremities of the circulation are under the control of the primary or organic nervous supply. Branches of nerves from those organic centres accompany every arterial vessel throughout the body to its termination, and without direction from our will regulate the contraction and dilatation of the blood-vessels to their most refined distribution. This fact was suspected by the older anatomists, but it remained for modern research to make it a demonstration. Thus it has now been proved that if the organic nervous supply of a part of the minute circulation be cut off by division of the organic nerve feeding that part, the vessels become paralysed, as these flexor muscles of my hand, which now grasp so firmly, would be paralysed were their voluntary nervous supply divided.

It will be clear at once that an important advancement of knowledge respecting the course of the blood through the minute circulation has been gained; but our knowledge does not rest at this point. When certain simple physical impressions are made upon the organic nerves, the disturbance of their supply is indicated by distant phenomena, and the blush which mantles, or the pallor which overspreads the cheek, under the influence of mental emotions or shock, are phenomena of this order.

---

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

I can bring to your notice an experiment, showing the production of paralysis, and of all the phenomena above quoted by the mere action of cold upon the organic nervous fibre. By evaporating ether from the back of my hand quickly, I freeze the skin, and thereby I produce paralysis. I take the ether away, and now into the paralysed vessels, which are capable of offering no efficient resistance, the blood rushes, distending the vessels, remaining for a moment stagnant in them, and giving a brilliant red colour or crimson blush over the part. I feel in this part the glow commonly called hot-ache; it is the blush which occurs on the cheeks, and it is from the same physiological condition.

Still further in advance, and with the mention of the fact I am brought back to the subject proper of my lecture; we have learned that certain chemical agents can so influence the organic nervous chain as to disturb its functions, after the manner of a pure physical act. When this peculiar fluid, the nitrite of amyl, to which I have before called your attention, came before me for investigation, I divined, from the symptoms it produced, that it influenced the organic nervous fibre precisely after the manner of a division of that fibre. I dipped a spill of paper into the liquid, brought that near to my nose, as I do now, inhaled the vapour, and immediately felt my face in a red glow, as you see it again at this moment, and felt my heart beating rapidly, as I feel it beating at the present time. I reasoned, naturally, and as events proved correctly, that this fluid, by its action on the organic nerves, paralysed the vessels of the minute circulation, and finding this to obtain with one chemical agent I traced it in others, and found a class of chemical substances, all of which have this same property of relaxing the blood-vessels at their extreme parts. The whole series of the nitrites possess this power; ether possesses it; but the great point I want to bring forth from this description is, that the substance we are specially dealing with, alcohol, possesses the self-same power. By this influence it produces all those peculiar effects which in every-day life are so frequently illustrated. It paralyses the minute blood-vessels, and allows them to become dilated with the flowing blood.

If you attend a large dinner party, you will observe after the first few courses, when the wine is beginning to circulate, a progressive change in some of those about you who have taken wine. The face begins to get flushed, the eye brightens, and the murmur of conversation becomes loud. What is the reason of that flushing of the countenance? It is the same as the flush from blushing, or from the reaction of cold, or from the nitrite of amyl. It is the dilatation of vessels following upon the reduction of nervous control, which reduction has been induced by the alcohol. In a word, the first stage, the stage of vascular excitement from alcohol, has been established.

The action of the alcohol extending so far does not stop there. With the disturbance of power in the extreme vessels, more disturbance is set up in other organs, and the first organ that shares in it is the heart. With each beat of the heart a certain degree of resistance is offered by the vessels when their nervous supply is perfect, and the stroke of the heart is moderated in respect both to tension and to time. But when the vessels are rendered relaxed, and resistance is removed, the heart begins to run quicker, like a watch from which the pallets have been removed, and the heart-stroke, losing nothing in force, is greatly increased in frequency, with a weakened recoil stroke. It is easy to account in this manner for the quickened heart and pulse which accompany the first stage of deranged action from alcohol, and you will be interested to know to what extent this increase of vascular action proceeds. The information on this point is exceedingly curious and important. After I had observed the effect of alcohol on the circulation generally, I attempted to calculate the rate at which it expedited the rate of circulation by observing its effect on the beat of the heart in the pigeon. Alcohol may be administered to this bird quite painlessly, and, as the animal quickly goes to sleep under the influence, and is therefore perfectly quiet, the beating of its heart can be calculated with precision. I traced in these observations an increase of beats of the heart amounting in the course of two hours to one-fourth beyond what was natural. Then I essayed to make researches on myself, but many circumstances intervened, connected with the persistent labour and anxiety of professional life, which prevented me conducting the necessary operations so correctly as I desired, and as I might perhaps at another time have done. Fortunately, the information has been far more ably supplied by the researches of Dr. Parkes, of Netly, and the late Count Wollowicz. The researches of these distinguished inquirers are so valuable, I make no apology for giving them in detail. The observers conducted their inquiry on the young and healthy adult man. They counted the beats of the heart, first at regular intervals, during what were called water periods, that is to say, periods when the subject under observation drank nothing but water; and next, taking still the same subject, they counted the beats of the heart during successive periods in which alcohol was taken in increasing quantities. Thus step by step they measured the precise action of alcohol on the heart, and thereby the precise primary influence induced by alcohol. Their results were as follows:—

"The average number of beats of the heart in twenty-four hours (as calculated from eight observations made in fourteen hours) during the first, or water period, was 106,000; in the alcoholic period it was 127,000, or about 21,000 more; and in the brandy period it was 131,000, or 25,000 more.

"The highest of the daily means of the pulse observed during the first, or water period, was 77·5; but on this day two observations are deficient. The next highest daily mean was seventy-seven beats.

"If, instead of the mean of the eight days, or 73·57, we compare the mean of this one day, viz., seventy-seven beats per minute, with the alcoholic days, so as to be sure not to over-estimate the action of the alcohol, we find:—

"On the 9th day, with one fluid ounce of alcohol, the heart beat 430 times more.

"On the 10th day, with two fluid ounces, 1,872 times more.

"On the 11th day, with four fluid ounces, 12,960 times more.

"On the 12th day, with six fluid ounces, 18,432 times more.

"On the 13th day, with eight fluid ounces, 23,904 times more.

"On the 14th day, with eight fluid ounces, 25,488 times more.

"But as there was ephemeral fever on the 12th day, it is right to make a deduction, and to estimate the number of beats in that day as midway between the 11th and 13th days, or 18,432. Adopting this, the mean daily excess of beats during the alcoholic days was 14,492, or an increase of rather more than 13 per cent.

"The first day of alcohol gave an excess of 4 per cent., and the last of 23 per cent.; and the mean of these two gives almost the same percentage of excess as the mean of the six days.

"Admitting that each beat of the heart was as strong during the alcoholic period as in the water period (and it was really more powerful), the heart on the last two days of alcohol was doing one-fifth more work.

"Adopting the lowest estimate which has been given of the daily work of the heart, viz., as equal to 122 tons lifted one foot, the heart, during the alcoholic period, did daily work in excess equal to lifting 15·8 tons one foot, and in the last two days did extra work to the amount of 24 tons lifted as far.

"The period of rest for the heart was shortened, though, perhaps, not to such an extend as would be inferred from the number of beats, for each contraction was sooner over.

The heart, on the fifth and sixth days after alcohol was left off, and apparently at the time when the last traces of alcohol were eliminated, showed in the sphygmographic tracing signs of unusual feebleness; and, perhaps in consequence of this, when the brandy quickened the heart again, the tracings showed a more rapid contraction of the ventricles, but less power than in the alcoholic period. The brandy acted, in fact, on a heart whose nutrition had not been perfectly restored."

(*To be continued.*)

Parliamentary and Law Proceedings.

Adulteration of Food and Drugs Bill.

The following Bill to Repeal the Adulteration of Food Acts, and to Make Better Provision for the Sale of Food and Drugs in a Pure State, was brought into the House of Commons on Friday, February 12, by Mr. Sclater-Booth. The second reading is fixed for Friday, February 19 :—

Whereas it is desirable that the Acts now in force relating to the adulteration of food should be repealed, and that the law regarding the sale of food and drugs in a pure and genuine condition should be amended:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. From *the commencement of this Act* the 23 & 24 Vict. c. 84, 31 & 32 Vict. c. 121, s. 24, and the 35 & 36 Vict. c. 74, shall be repealed, except in regard to any appointment made under them and not then determined, and in regard to any offence committed against them or any prosecution or other act commenced and not concluded or completed, and any payment of money then due in respect of any provision thereof.

2. This Act shall not apply to Scotland or Ireland except as herein provided.

3. The term "food" shall include every article eaten or drunk by man, other than drugs:

The terms "drug" shall include medicine for internal or external use:

The term "county" shall include every county, riding, and division, as well as every county of a city or town, not being a borough:

The term "justices" shall include any police and stipendiary magistrate invested with the powers of a justice of the peace.

Description of Offences.

4. No person shall knowingly mix, colour, stain, or powder, or order any other person to mix, colour, stain, or powder, any article of food with any ingredient or material of a nature injurious to health, with intent that the same may be sold in that state, and no person shall knowingly sell any such article so mixed, coloured, stained, or powdered, under a penalty in each case of fifty pounds for the first offence; every subsequent offence, after a conviction in such penalty, shall be a misdemeanor, for which the person, on conviction, shall be imprisoned for a period not exceeding six months with hard labour.

5. No person shall knowingly, except for the purpose of compounding as hereinafter described, mix, colour, stain, or powder, or order any other person to mix, colour, stain, or powder, any drug with any other ingredient or material of a nature injurious to health, with intent that the same may be sold in that state, and no person shall knowingly sell any such drug, so mixed, coloured, stained, or powdered, under the same penalty as in the last clause for a first and subsequent offence.

6. No person shall knowingly sell any article of food or any drug which is not of the nature, substance, and quality of the article demanded by the purchaser, under a penalty of *twenty* pounds, except as herein excepted and provided; that is to say, except—

Where any matter is mixed therewith for the purpose of rendering it portable, or of preserving it;

Where a harmless ingredient is mixed with it for the purpose of rendering it palatable or of improving its appearance;

Where according to the usage of trade it is sold in a mixed state;

Where it is the subject of a patent in force, and is supplied in the state required by the specification of the patent;

Where British, colonial or foreign spirits are reduced from their ordinary strength by persons licensed and paying duties under the excise;

Where a drug is compounded either in conformity with a prescription of a registered medical practitioner or otherwise, according to the usage of trade;

Where the article is unavoidably mixed with some extraneous matter.

7. No person shall sell any article mixed for any of the purposes mentioned in the exceptions above set forth, if the matter mixed be more than is ordinarily required for the purpose, under a penalty of *ten* pounds.

No person shall sell any article of food which by the usage of trade is sold in a mixed state, unless the ingredients shall be mixed in the proportions required by such usage, and no person shall sell any compounded drugs, except the same shall be compounded according to the prescription in writing submitted for that purpose, or in accordance with the regulations prescribed by the British Pharmacopœia issued by the General Medical Council, or with a basis to be laid down by the Pharmaceutical Society, or the Local Government Board, or the Privy Council, subject to a penalty of *twenty* pounds.

8. Provided that no person shall be guilty of an offence in respect of the sale of an article mixed with any ingredient not injurious to health, whether the case may or may not fall within any of the above mentioned exceptions, if at the time of delivering such article he shall supply to the person receiving the same a notice to the effect that the article is mixed, by a label written or printed on or with the article.

9. No person shall knowingly, and with the intent that the same may be sold in its altered state without notice, abstract from an article of food any part of it so as to affect injuriously its quality, substance, or nature, and no person shall knowingly sell any article so altered without making disclosure of the alteration, under a penalty in each case of *ten* pounds.

Appointment and Duties of Analysts, and Proceedings to obtain Analysis.

10. In the city of London and the liberties thereof, the commissioners of sewers of the city of London and the liberties thereof, and in all other parts of the metropolis the vestries and district boards acting in execution of the Act for the better local management of the metropolis, the court of quarter sessions of every county, and the town council of every borough having a separate court of quarter sessions, or having under any general or local Act of Parliament or otherwise a separate police establishment, may, as soon as convenient after the passing of this Act, where no appointment has been hitherto made, and in all cases as and when vacancies in the office occur, and when required so to do by the Local Government Board, shall, for their respective city, districts, counties, or boroughs, appoint one or more persons possessing competent knowledge, skill, and experience, as analysts of all articles of food and drugs sold within the said city, metropolitan districts, counties, or broughs, and shall pay to such analysts such remuneration as shall be mutually agreed upon, and may remove him or them as they shall deem proper; but such appointments and removals shall at all times be subject to the approval of the Local Government Board, who may require satisfactory proof of competency to be supplied to them, and

may give their approval absolutely or with modifications as to the period of the appointment and removal, or otherwise.

11. The town council of any borough may agree that the analyst appointed by any adjoining borough or for the county in which the borough is situated, shall act for their borough during such time as the said council shall think proper, and shall make due provision for the payment of his remuneration, and if such analyst shall consent, he shall during such time be the analyst for such borough for the purposes of this Act,

12. Any purchaser of any article of food in any district, county, city, or borough where there is any analyst appointed under this or any Act hereby repealed shall be entitled, on payment to the analyst, or if there be no such analyst then acting for the district to the analyst of a neighbouring district, of a sum not more than ten shillings and sixpence, as shall be agreed upon between such person and the analyst, to have such article analysed by such analyst, and to receive from him a certificate of the result of his analysis.

13. Any medical officer of health, inspector of nuisances, or inspector of weights and measures, or any inspector of a market, or any pol'ce constable under the direction and at the cost of the local authority appointing such officer, inspector, or constable, may procure any sample of food or drugs, and if he suspect the same to have been sold to him contrary to any provision of this Act, shall submit the same to be analysed by the analyst of the district or place for which he acts, and such analyst shall with all convenient speed analyse the same and give a certificate to such officer, wherein he shall specify the result of the analysis.

14. The person purchasing any article with the intention of submitting the same to analysis shall, after the purchase shall have been completed, notify to the seller or his agent selling the article his intention to have the same analysed by the public analyst, and shall offer to divide the article into three parts to be then and there separated, and each part to be marked and sealed, or fastened up in such manner as its nature will permit, and shall, if required to do so, deliver one of the parts to the seller or his agent.

He shall afterwards retain one of the said parts for future comparison, and submit the third part, if he deems it right to have the article analysed, to the analyst.

15. It the seller or his agent do not accept the offer of the purchaser to divide the article purchased in his presence, the analyst receiving the article for analysis shall divide the same into two parts, and shall seal or fasten up one of those parts, and shall cause it to be delivered, either upon receipt of the sample or when he supplies his certificate to the purchaser, who shall retain the same for production in case proceedings shall afterwards be taken in the matter.

16. If the analyst do not reside within two miles of the residence of the person requiring the article to be analysed, such article may be forwarded to the analyst through the post office as a registered letter, subject to any regulations which the Postmaster General may make in reference to the carrying and delivery of such article, and the charge for the postage of such article shall be deemed one of the charges of this Act or of the prosecution, as the case may be.

17. If any such officer, inspector or constable, as above described, shall apply to purchase any article of food or any drug exposed to sale, and shall tender the price for the quantity which he shall require for the purpose of analysis, not being more than shall be reasonably requisite, and the person exposing the same for sale shall refuse to sell the same to such officer, inspector, or constable, such person shall be liable to a penalty of five pounds.

18. The certificate of the analysis shall be in the form set forth in the schedule hereto, or to the like effect.

19. Every analyst appointed under any Act hereby repealed or this Act shall report quarterly to the authority appointing him the number of articles analysed by him under this Act during the foregoing quarter, and shall specify the result of each analysis, and such report shall be read at the next meeting of the authority appointing such analyst.

Proceedings against Offenders.

20. When the analyst having analysed any article shall have given his certificate of the result, from which it may appear that an offence against some one of the provisions of this Act has been committed, the person causing the analysis to be made may take proceedings for the recovery of the penalty herein imposed for such offence, before any justices having jurisdiction in the place where the article or drug sold was actually delivered to the purchaser, in a summary manner.

Every penalty imposed by this Act shall be recovered in the manner prescribed by 11 & 12 Vict. c. 43, and may be mitigated according to the judgment of the justices.

21. At the hearing of the information in such proceeding the production of the certificate of the analyst shall be sufficient evidence of the facts therein stated, unless the defendant shall require that the analyst shall be called as a witness, and the parts of the articles retained by the person who purchased the article shall be produced, and the defendant may, if he think fit, tender himself and his wife to be examined on his behalf, and he or she shall, if he so desire, be examined accordingly.

22. The justices before whom any complaint may be made under this Act may, upon the request of either party, in their discretion cause any article of food or drug to be examined and analysed by the analyst of an adjoining district, who shall thereupon make the analysis as if he were applied to by any officer in his district, and may be required to attend to give evidence at the hearing of the case; and the expense of such examination, analysis, and attendance shall be deemed part of the expenses of executing this Act, unless the justices order the same to be paid by the complainant or the defendant.

23. Any person who has been convicted of any offence punishable by any Act hereby repealed or this Act by any justices may appeal to the next general or quarter sessions of the peace which shall be held for the city, county, town, or place wherein such conviction shall have been made after the expiration of ten days from the day when such conviction shall take place, provided that such person enter into a recognizance within three days next after such conviction, with two sufficient sureties, conditioned to try such appeal, and to be forthcoming to abide the judgment and determination of the court at such general or quarter sessions, and to pay such costs as shall be by such court awarded; and the justices before whom such conviction shall be had are hereby empowered and required to take such recognizance; and the court at such general or quarter sessions are hereby required to hear and finally determine the matter of such appeal, and may award such costs to the party appealing or appealed against as they shall think proper.

24. In any prosecution under this Act, where the fact of an article having been sold in a mixed state has been proved, if the defendant shall desire to rely upon any exception or provision contained in this Act, it shall be incumbent upon him to prove the same.

25. If the defendant in any prosecution under this Act, prove to the satisfaction of the justices or court that he sold the article in the same state as when he himself purchased it, and that he bought it, as the same article in nature, substance, and quality as that demanded of him, and with a warranty in writing to that effect, he shall be discharged from the prosecution, but no order for costs, shall be made in the case, unless he shall raise any other question which shall be decided against him, in which case he shall be liable to pay the costs incurred by such question.

26. Every penalty imposed and recovered under this Act shall be paid in the case of a prosecution by any officer, inspector, or constable, to the prosecutor, and shall be by such prosecutor paid to the authority for whom he acts, and be applied towards the expenses of executing this Act.

27. Any person who shall forge, or shall utter, knowing it to be forged for the purposes of this Act, any certificate or any writing purporting to contain a warranty, shall be guilty of a misdemeanor and be punishable on conviction by imprisonment for a term of not exceeding *two* years with hard labour.

28. Nothing in this Act contained shall affect the power of proceeding by indictment, or take away any other remedy against any offender under this Act, or in any way interfere with contracts and bargains between individuals, and the rights and remedies belonging thereto.

Expenses of Executing the Act.

29. The expenses of executing this Act shall be borne, in the city of London and the liberties thereof, out of the consolidated rates raised by the commissioners of sewers of the city of London and the liberties thereof, and in the rest of the metropolis out of any rates or funds applicable to the purposes of the Act for the better local management of the metropolis, and in counties out of the county rate, and in boroughs out of the borough fund or rate.

Special Provision as to Tea.

30. From and after the first day of January one thousand eight hundred and seventy-six all tea imported as merchandise into and landed at any port in Great Britain or Ireland shall be subject to examination by persons to be appointed by the commissioners of customs for the inspection and analysis thereof, for which purpose samples may, when deemed necessary by such inspectors, be taken and with all convenient speed be examined by the analysts to be so appointed; and if upon such analysis the same shall be found to be unwholesome, mixed with other substances or exhausted tea, the same shall not be delivered unless with the sanction of the said commissioners, and on such terms and conditions as they shall see fit to direct, either for home consumption or for use as ships stores or for exportation; but if on such inspection and analysis, it shall appear that such tea is in the opinion of the analyst unfit for human food, the same shall be forfeited and destroyed or otherwise disposed of in such manner as the said commissioners may direct.

31. Tea to which the term "exhausted" is applied in this Act shall mean and include any tea which has been deprived of its proper quality, strength, or virtue by steeping, infusion, decoction, or other means.

32. This Act shall commence on the *first day of October one thousand eight hundred and seventy-five.*

33. This Act may be cited as "The Sale of Food and Drugs Act, 1875."

SCHEDULE.

Form of Certificate.

To * and .

To all to whom it may concern.

I, the undersigned, public analyst for the , do hereby certify that I received on the day of , 18 , from † , a sample of for analysis, which then weighed , and have analysed the same, and declare the result of my analysis to be as follows:—

The said sample contained the parts as under.

---

*Observations.**

I return the residue of the sample not consumed in the analysis herewith.

As witness my hand this day of , 18 .

A.B.,
at .

* Here insert the name of the person submitting the article for analysis.

† Here insert the name of the person delivering the sample.

* Here the analyst may insert at his discretion his opinion as to whether the mixture (if any) was for the purpose of rendering the article portable or palatable, or of preserving it, or of improving the appearance, or was unavoidable, and may state whether in excess of what is ordinary, or otherwise, and whether the ingredients or materials mixed are or are not injurious to health.

THE ALLEGED SALE OF ADULTERATED SULPHUR.

At the Leeds Town Hall on Wednesday, the adjourned summons before Mr. Bruce, against Mr. Joseph Harrison, chemist, Stanningley, was heard. The summons had been issued under the Adulteration Act, 1872, at the instance of the Superintendent of the Sanitary Department, and charged the defendant with selling, on the 2nd instant, as precipitated sulphur, 4oz. of sulphur, which was adulterated to the extent of 64 per cent. with sulphate of lime. The Town Clerk prosecuted, and Mr. Granger appeared for the defendant.

Mr. Brooke (Hirst, Brooke, and Hirst), wholesale druggist, said that sulphur præcipitatum as prescribed by the Pharmacopœia of 1867 was pure sulphur; lac sulphuris contained sulphate of lime. Both were prepared by precipitation. Since the present proceedings had been instituted he should supply the pure article, viz., that mentioned in the new Pharmacopœia, if precipitated sulphur were asked for. Previously if precipitated sulphur had been asked for it would have depended on the price quoted as to which of the two kinds he would have supplied. His price list had been altered since the question had come before the court.

Mr. Scattergood, surgeon, was then called.

Mr. Granger asked whether it was advisable to have medical evidence.

Mr. Bruce: Yes, I think so. Supposing Mr. Harrison should be convicted, it would be of great benefit to the druggists that they should know what they are doing. Mr. Harrison does not wish to do a thing which is contrary to the law, therefore, I should suppose he would desire to have the fullest evidence on the subject.

Mr. Scattergood said the compilers of the Pharmacopœia attached so much importance to the fact that the precipitated sulphur of the new Pharmacopœia should be pure that they had given tests. The terms milk of sulphur and precipitated sulphur had always been held to be synonymous by writers on materia medica. Lac sulphuris was left out of the new Pharmacopœia, and sulphur præcipitatum was the only term used for precipitated sulphur. He believed that the reason for altering the formula for preparing precipitated sulphur was because by the mode originally adopted it could not be obtained without an admixture of sulphate of lime. When people got what was supplied as precipitated sulphur, it was very often not effectual as a medicine, because it was not pure sulphur. The complaint that it was difficult to get the article pure had led to its disuse in medicine to a great extent. Sulphur was usually ordered for its purgative action. Sulphate of lime was not a purgative at all; the best that could be said of it was that it was inert. When he prescribed precipitated sulphur he expected that the pure article would be supplied.

By Mr. Granger: He very rarely used precipitated sulphur. He knew that milk of sulphur was very often used. He took the terms to be synonymous, milk of sulphur being the adulterated article.

Mr. Smeeton, chemist, stated that if he were asked for precipitated sulphur he should supply a pure article.

By Mr. Granger: He had altered his labels for milk of sulphur since the prosecutions began, adding the words "Contaminated with sulphate of lime." He had had the pure article brought back by customers two or three times. In poor neighbourhoods milk of sulphur was generally preferred, but his customers, as a rule, knew the difference.

Mr. Granger then raised the same defence as the defendant set up when the case was last before the court, viz., that there were two kinds of precipitated sulphur, one of which was identical with milk of sulphur, and therefore containing sulphate of lime, and the other the pure sulphur. It appeared, he said, that many of the druggists were altering their price lists, etc., as a consequence of the present proceedings; what they had hitherto done having been done simply from ignorance, and not with any intent to defraud the public.

Mr. Bruce said there was no imputation that either Mr. Harrison or any of the druggists had made any attempt to defraud.

For the defendant Mr. Thomas Walker, chemist, was called, and he contended that milk of sulphur was often asked for under the name of precipitated sulphur, and had been called by that name in the old Pharmacopœias. In his neighbourhood where the customers were chiefly of the poorer class, milk of sulphur was greatly preferred to the pure sulphur, which had been returned to him on several occasions.

Mr. Bruce stated that according to the new Pharmacopœia precipitated sulphur was a pure article without a trace of lime in it, and when therefore a person asked for it he had a right to have it, and not an article that contained 36 parts of sulphur and 64 of sulphate of lime. Whilst he could not do otherwise than convict, still it seemed to him that Mr. Harrison had only been doing what all the other druggists had been doing, without a knowledge that it was improper. That was proved by the evidence on both sides, and Mr. Harrison would leave the court without a stain on his character. A fine of 1*s.* was imposed, it being understood that this was only a test case.

The Town Clerk remarked that ignorance would no longer be an excuse.

The Town Clerk applied for costs, but Mr. Bruce did not think it was a case in which he was entitled to them.

Mr. Geo. Teasdale, chemist, Bramley, was summoned for a similar offence, and a fine of 1*s.*, without costs, was inflicted.—*Yorkshire Post.*

Poisoning by Chloral Hydrate.

On Friday, February 12, Dr. Hardwicke held an inquest at Bloomsbury on the body of Edward P. Kendall. Mr. J. W. Barnes, surgeon, said when he first saw deceased he had been dead some time; he was dressed, lying on his right side, both his feet drawn up, and arms folded. His nails were dark, and there was a frothy mucus on the pillow. Witness saw two bottles, one of which had contained a solution of hydrate of "chloral" and one of "syrup." They were both empty. He made a post-mortem examination, and was induced to believe the cause of death was an over or poisonous dose of hydrate of chloral.

Mr. William Blades, assistant to Mr. Cooper, chemist, of Oxford Street, said he knew deceased as a customer, coming usually on a Sunday for chloral and sedative mixtures, owing, as he said, to want of sleep. On Sunday last he asked for "hydrate of chloral," which witness told him was in crystals and the crystals being rather large it would be awkward of him to judge of a dose, which was 20 grains. Deceased wanted eight doses, and witness suggested his having it in solution, and gave him 160 grains in solution, a 1½-ounce bottle labelled "poison," and the doses were also marked by a paper label. Witness had dispensed 60 grains of chloral to be taken in four hours, and up to the present time he had not known of any bad consequences of taking chloral, which had become a fashionable remedy for want of sleep.

The Coroner, in summing up, said the practice of taking chloral ought to be checked. Its action was far more powerful than alcohol, and again it underwent changes and its properties were therefore altered, and what would be a harmless dose at one time might become an overdose at another, especially under the effects of light. It was also doubly dangerous to persons of intemperate habits.

The jury returned a verdict that "the deceased died from the effects of taking an overdose of 'hydrate of chloral,' and that in their opinion the same was brought about by misadventure."—*Standard.*

Poisoning by Laudanum.

Two inquests have been held in Leeds within the last few days, in each of which a verdict was returned that the deceased had been poisoned by laudanum.

In one case it appeared from the evidence that the deceased lived with a woman who was in the habit of taking daily a large amount of laudanum. She admitted in evidence that she had on one occasion taken as much as six ounces in one day. It was shown that deceased purchased an ounce of laudanum, but there was no evidence to show whether he took it or not. In the evening he went to sleep and became unconscious, and, subsequently, a surgeon was called in and applied the stomach pump and other remedies, but the deceased died the following evening. The Coroner said there was no evidence to show by whom the laudanum had been administered, and advised the jury to return an open verdict.

The second inquest was on the body of William Jackson, chemist and druggist, late of Bradford. The deceased, it appeared, had been in the habit of taking laudanum for neuralgia, and whilst on a visit to some friends took, it was supposed, three or four ounces of laudanum. He went to sleep, and on getting up on the following morning still appeared drowsy. About dinner-time a doctor was called in, but the deceased never rallied, dying about twenty-four hours after taking the dose. The jury were of opinion that the deceased did not intend to commit suicide, and returned a verdict that "death was accidentally caused by taking an overdose of laudanum."

Notes and Queries.

[428]. EXT. HÆMATOXYLI.—Can any reader inform me how the bright colour imparted to solution of Ext. Hæmatoxili by caustic potash can be rendered permanent?—Wm. J. Cooper.

NOTE ON POMADES.—The question has often been asked by correspondents how the misty appearance so often perceived in bottles of pomade, apparently between the pomade and the glass, may be avoided.

After trying all the plans suggested without success, I adopted the expedient of dipping the bottles, after the pomade has become cold, into warm water for about a minute, when the misty appearance entirely disappears. I have never found the above plan to fail.—Leontodon.

PHARMACEUTICAL REMUNERATION, ETC.

Sir,—As an old stager, having entered the drug trade somewhere about thirty-five years since, you will perhaps allow me to say a few words before the present exciting controversy is closed.

Now it did not seem to me that anything contained in the first letter of "Veritas" indicated in the least a twenty years' sleep; most reasonable persons could see that it was written with the intention of showing that things were greatly improved inside the pharmaceutical sphere, as well as outside its boundaries, and if we had not kept pace with other trades and other classes of the community, it was in a great measure owing to the peculiarity of our business, which entailed upon us exceptional obligations.

My experience quite agrees with most of his statements of course excluding the typical "apprentice," for there are now, as there were then, hard and exacting employers, as there were, and are, kind and considerate ones.

I must conscientiously coincide with every word he says to "An Examined Assistant" and particularly, as regards "unemployed time in business hours," the very mention of which shows "An Examined Assistant" to be no man of business.

The second letter of "Veritas" appears to have more of a personal character; written when just recovering from sickness, and under irritation caused by remarks made upon his letter by "An Examined Assistant;" so that remembering "Nemo mortalium omnibus horis sapit," it would have remained unnoticed by me had it not contained that startling statement upon pharmaceutical remuneration which seems to have overwhelmed others as well as myself with astonishment, as the numerous letters appearing week after week in your columns amply testify. Now all extremes are bad. Extreme statements are mostly mischievous.

I could point to a man who entered the drug trade without any capital except his head and his hands, who rose to be the head of a large wholesale firm, and who retired with great wealth; but while this might be legitimately adduced as an example of what it was possible for *one*, under certain circumstances, by dint of industry and energy, to accomplish, it would be very ridiculous to make the sweeping statement that *all* young men entering the drug trade might reasonably expect to become millionaires.

"Veritas" has both facts and experience against him, and this is so patent to all who choose to make use of their ordinary powers of observation, that it were scarcely worth confuting him but for this—that men are too apt to welcome with eagerness any extravagant statement which but promises enough and prophesies enough, whether it be confirmed by a single particle of evidence or not.

I know something of the rule of geometrical progression by which the thirty-two nails in a horse's shoes, beginning at a farthing the first nail, are made to amount to a marvellous sum. I have also read a little about the law of natural selection, by which the weaker is supposed to be crushed out in the struggle for existence. But although there has been a great display of arithmetic in your columns over the question, I do not think the first would exactly apply, the latter would not be kind, and moreover the £200 man would be the most likely to be the victim.

No sensible man with £200 or £300 will reasonably expect any such amount of success, the limits of the drug trade pretty clearly indicating that all such cases must be very exceptional, and further, I would strongly advise his putting aside all thoughts of horseflesh until at all events he has secured his £500 retiring allowance, or it will greatly retard its attainment. There is far less chance for him if he endeavours to perform this feat on horseback.

As to taking a wife it is better not to hazard an opinion any further than this: if he means to do it at all, I think one would recommend the wife first, for if the horse takes the first place in the affections it may perhaps keep there.

"Veritas," in his last letter, fights hard and thinks he has demolished all his opponents, but although he says so, he has not in any way proved the truth of his assertion. Need a man submit to the fare of an anchorite and other privations to be able to retire into inactivity in the prime of life? I hope many of your younger readers will say—No.

Just a line as to pharmaceutical hours of business. This knotty point will never be solved by letter writing. If masters will be considerate and young men reasonable, little cause for complaint need exist.

Employers are doing great things in the way of improving the old condition of things. Young men are often both exacting and unreasonable. I would in all kindness put before them an old exhortation—"Let not your good be evil spoken of."

If time given for study, attending lectures, etc., makes you all the more diligent in business hours, your employer will feel encouraged in making sacrifices; but if (as is too often the case) you are never seen studying in your own time, and his business too is neglected, you do not deserve much consideration, nor ought you to expect any.

ONE WHO HAS KNOWN THE DRUG TRADE MORE THAN THIRTY YEARS.

Sir,—I think many of us who are young men and about to start in business have cause to be thankful to "Veritas" for his very cheering letters.

It has been the custom of late years (at any rate, among assistants) to talk disparagingly of the future prospects of chemists and druggists, and a very common saying has been—"Oh, it is no use to pass the examinations, for unless a fellow has £700 or £800 he will never get a business worth anything." The effect of such a feeling has been to discourage many from seeking to obtain either the Minor or Major qualification.

Hence, I think that such bold and manly letters as "Veritas" has written are likely to be productive of great good, by inspiring the hearts of the poorer class of assistants with the hope that they may one day become masters of lucrative businesses, although their means to commence with may be but small. Such a hope would prove a great incentive to study and practical work, and go a far greater length to make them happy than even the closing of the establishment an hour earlier than usual.

M. P. S.

Sir,—The following table, showing the sums necessary to be laid by annually in order to acquire £10,000 in the course of fifteen years, may interest those who have read the correspondence elicited by the statement of "Veritas." It is assumed that the young man of twenty-five has purchased with his £300 a business, of which the returns are at first £500 per annum, out of which he contrives to lay by one-fourth. I leave it to each of your readers to form his own judgment as to the probable percentage of persons, confining themselves to a chemist's legitimate business, who could, with so small an outlay secure such a desirable result.

Years.	Net Annual Profit.		Years.
1st.	£125	£259	15
2nd.	170	336	14
3rd.	230	433	13
4th.	300	538	12
5th.	400	684	11
6th.	500	814	10
7th.	600	930	9
8th.	600	886	8
9th.	600	844	7
10th.	600	804	6
11th.	600	766	5
12th.	600	729	4
13th.	600	694	3
14th.	600	661	2
15th.	600	630	1
		£10,008	

The third column shows the amount of the annual profit improved at 5 per cent. compound interest for the number of years specified in column four.

"COMPOUND INTEREST."

Sir,—A typographical error occurs in my last letter in your columns. "In this city the shops are ostensibly closed at six." "Six" should been "eight."

VERITAS.

February 13, 1875.

PHARMACEUTICAL EXAMINATIONS.

Sir,—I am very glad to see that Mr. Greenish has brought before the Council the question of the equal (or otherwise) severity of the Pharmaceutical Examinations, as conducted respectively in London and Edinburgh.

That three months should elapse before a candidate who has failed can again present himself for examination, is generally understood to be the rule, but I rather doubt if such a law is, or at any rate was, always insisted on, for I certainly remember hearing of an instance, in which a candidate who had been thrice plucked in London presented himself at Edinburgh (I think in the very next month after his third failure), came out in honours, and following up his successes also passed his Major Examination at the "Modern Athens" at the end of another three months.

If such ever was the case, we may alter the old saying into "they can manage these things better in Scotland."

Mr. Hampson remarked that "statistics to be of any value must cover a somewhat prolonged period;" but about two years ago I called your attention to the different percentage of failures at the two places of examination, and do not think there has been much variation in it since.

Under these circumstances it certainly seems the duty of the Council to inquire into the cause, and I would venture to suggest (without in the slightest degree wishing to insinuate that such is the case) that it would be advisable to see whether any of the London Board of Examiners, in an excess of zeal for the higher education of pharmacists, do not ask questions in their particular departments, which may be considered as almost too severe when compared with those put by the other members of the Board.

This might, I imagine, be ascertained by a comparison of the numbers of the victims in the various subjects (for I presume that the examiners usually take the same), and would surely be a fit object for the inquiries of a committee of the Council, a report from which would doubtless prove that candidates have no more to fear plucking at the hands of any one or two of the examiners than they have from the others.

EDWARD H. STOREY.

42, *Castle Street, East, W.,*
February 15, 1875.

EARLY CLOSING.

Sir,—The early closing at Bedford certainly answers very well, but Mr. Waring did not speak "to the card" when he stated that medicines only are supplied after the shops are closed, no limitation of that kind being made. With regard to "every chemist keeping three or four assistants," that was simply a stretch of his imagination, for there are only two chemists in the town who employ more than two pairs of hands, reckoning assistants and apprentices together, and at the present time, I believe, there are only three or four paid assistants in the town; so that Mr. Waring must either have left Bedford for some considerable time or be troubled with a very short memory. The fact is, the medical profession, as in many other towns, dispense their own prescriptions, so that there is very little chance of getting much of a dispensing business, the main part of the trade consisting of the ordinary chemists' sundries, combined with such pharmaceutical products as paints, petroleum, and tar. "Veritas" is welcome to come and "take stock," and will, I am sure, meet with civility from any chemist of whom he may make inquiries, but I am afraid he will not find it such an El Dorado as he has been led to expect. I can tell him for his comfort that no less than three chemists have commenced business in Bedford within the last few years, and none of them could succeed in getting a living.

A BEDFORDIAN.

A. Plimsoll.—You will find the process described in the British Pharmacopœia, under the head of "Ferrum Redactum."

"*Erratum.*"—We are requested by Mr. Lowe to make the following correction in his letter in last week's issue. In the tenth line of the last paragraph but three, for "is *now* much less incorrect," read "is *not* much less incorrect."

"*Leontodon.*"—See an article by Mr. J. Spiller on "Nickel Plating as applied to Photographic Purposes," in the *Pharm. Journ.* for Nov. 4, 1871, p. 368.

"*Inquirer.*"—We do not think a qualification to enter the medical profession could be acquired in the manner described, but the question had better be addressed to one of our medical contemporaries.

H. Foster.—The first label would, in our opinion, be liable to a stamp; the second probably so; the third we think would not. But decisions of the Commissioners have shown the grounds upon which they have been made to be so indeterminate by outsiders that, to be safe, it would be better to submit the labels to the Board.

J. Browne.—A fresh volume of the *Pharmaceutical Journal* is commenced in the first issue in July of each year.

"*Student.*"—This is a preparation mentioned in Squire's 'Companion' as having been made at the suggestion of Dr. Spencer Wells. A note in reference to it will be found in *Pharm. Journ.* for April 19, 1873, p. 821.

J. S.—Most manuals of chemistry, including those mentioned by you, define the fundamental chemical principles upon the application of which the answers to the questions sent would depend.

"*Quærens.*"—No such list is kept at Bloomsbury Square. Perhaps you might obtain the information by applying at the office of the Crown Colonies Commission, 12, Spring Gardens, S.W.

J. Garth.—(1) The arms are those of the Pharmaceutical Society as a corporate body, and no legal right exists to use them in any other way. (2) We cannot say; apply at Apothecaries' Hall. (3) This question should be submitted to the Registrar of the Medical Council.

M. D.—Bleached sponge is prepared by soaking ordinary sponge in very dilute hydrochloric acid, then in several successive quantities of cold water, afterwards in water containing a little sulphurous acid or chlorine. Finally the sponge is repeatedly washed in clean water.

J. Bradshaw and *A. P. S.*—We are unable to give advice upon medical subjects.

"*Theta.*"—Phospho-molybdic acid is prepared by digesting with the aid of heat freshly precipitated molybdic acid, with sufficient solution of phosphoric acid to dissolve it.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. E. Smith, Mr. S. Taylor, Mr. Haselden. Mr. Ince, Mr. Bell, Mr. Baynes, Mr. Pocklington, Mr. Plimsoll, Mr. E. J. Searle, Mr. A. C. Bowdler, Mr. Reynolds, Mr. A. Warren, "One who values Time and loves Study," H. F., C. D.

ON SOME ADULTERATED PEPPER.

BY HENRY POCKLINGTON, F.R.M.S.

Shortly after the Bradford exposure of the tricks of the pepper trade, an examination of the contents of the domestic pepper-box induced me to make sundry examinations of various peppers purchased or otherwise obtained from different sources in Leeds, with results quite different from my expectations. In common, I believe, with many others interested in food analysis, I have been under the impression that pepper has been very little adulterated notwithstanding its present exemption from excise supervision; but so far as Leeds is concerned,—and I have not at present extended my observations beyond its bounds,—there is no doubt that this impression is an erroneous one, and that vast quantities of a highly sophisticated article are in the market. Under these circumstances, it occurs to me that a short notice of the three groups, into which the specimens I have examined may be arranged, may be of interest, and perhaps of value, to West Riding pharmacists in particular and to the readers of the Journal in general. I regard this as the more probable since the worst specimens that I have examined have been procured, not from small chandlers' shops, but from respectable pharmacists in poor neighbourhoods.

The first sample examined was supplied to my family in the ordinary way, and is quite characteristic of some manufacturers doing an extensive trade amongst small shopkeepers either directly or through the medium of a wholesale house. I am of opinion the latter. This pepper was adulterated to the extent of 50 per cent. with various farinas, of which a species of so-called Brazilian arrowroot, a "yam" starch, forms by far the largest proportion. There was a small quantity of rice starch and a little wheat flour present. The arrowroot granules are large, of an exaggerated "mussel" shape, and polarize very brilliantly. The starches appear to have been damaged by water and to have been subsequently stove dried. Fragments of the mycelium of fungi and spores could be detected.

Sample No. 2.—This was supplied by a firm of pepper grinders direct to a respectable pharmacist under special warranty that it was genuine. It proved to be *black* pepper adulterated with about 60 per cent. of "pea-meal," locust-beans in very small quantities, wheat, and rice starch. It has been frequently met with in Leeds and Bradford.

Sample No. 3.—This differs exceedingly from the preceding, and I have no idea as to its origin, the specimen having been handed me for examination without any indication of the source whence it was derived. It is largely adulterated with farinas, amongst which are small quantities of wheat-starch, oatmeal, and a compound starch of which I have not as yet determined the nature. This sample is also adulterated with a somewhat notable quantity of lime, and is singularly devoid of flavour. I have only seen one sample. There can be little doubt that the major portion of the pepper supplied to small shops in this locality is more or less adulterated. The sophistication is extremely easy of detection by any one possessed of a microscope, as the characters of genuine ground pepper are utterly unlike those of the substances mixed with it. The following plans answer well in practice.

Take a small quantity of the suspected pepper on the point of a clean spatula and place it on a glass slip, add a drop of water, and mix the pepper with the water. Place on the usual thin cover and examine with a quarter-inch objective. The presence of starch will at once be detected and the nature determined by its salient features. Those not familiar with the microscopical appearance of starch granules will derive great assistance from the use of iodine solution, which will at once stain the granules with the characteristic blue violet coloration. More efficient service, however (since genuine pepper contains starch in very characteristic and minute granules) is rendered by the use of the micro-polariscope which shows the starch granules brilliantly white on the dark ground and marked with their several black crosses. When the analyst intends to avail himself of this method, he will find it desirable to moisten the pepper on the slide with either oil of cloves or thin Canada balsam or dammar, as the bi-refractive intensities of the starch granules are very considerably exalted by the use of these media. The approximate percentage of starch present may be obtained by separation of the starch from the pepper by the usual methods pursued in the preparation of starch. The mixture is well agitated in a test tube with plenty of water and allowed to rest a short time. The heaviest portions including nearly all the fragments of pepper will speedily subside. The water has now to be poured into another tube and the suspended starch allowed to subside. Comparison of the amounts of the two precipitates will give fairly accurate results, but each precipitate should be microscopically examined. It might be mentioned that this method much facilitates the diagnosis of the starches employed as adulterants. Any floating particles should be examined microscopically, as they will include fragments of the husks of the pepper and any cereals employed.

WHAT IS A SYNONYM?

BY A. F. HASELDEN, F.L.S.

Upon an occasion this was a question in the Preliminary Examination. How it was answered forms no part of this communication, but I have often thought how little as a matter of teaching the subject is brought to the notice of our students.

The Pharmacopœia abounds in synonyms: it is questionable whether they receive sufficient attention. It appears to me that the Pharmacopœia does not go back far enough in its synonyms, although when compared with former Pharmacopœias written in Latin it is decidedly in advance. In reading the prescriptions of young members of the professions of medicine and surgery the information may be sufficient; but is it equally so for those of older dates? Prescriptions of twenty, thirty, or even forty years ago are still dispensed either from the original or a copy in the prescription book. When the Pharmacopœia was written in Latin, translators like Phillips and Collier considered it one of the important features of the work to give the various names applied through many previous Pharmacopœias to the same article.

The British Pharmacopœia of 1867, as a rule, gives only in addition to the name used in the work that of the last edition of the London, Edinburgh, or Dublin Pharmacopœias. In the case of hydrargyri perchloridum, as also in hydrargyri subchloridum, the synonyms of 1864 are added, namely, for the former hydrargyrum corrosivum sublimatum, and for the latter, calomelas.

May it not be worth while, in the interest of those now studying, to draw attention to the matter of synonyms or former names and present names? Let me take one of the preparations of mercury of the B.P.—

Name—Hydrargyrum Ammoniatum.
Syn.—Hydrargyri Ammonio-Chloridum, London and Dublin.
Hydrargyri Præcipitatum Album, Edinburgh.

For this in Phillips's translation of the London Pharmacopœia I find—

Name—Hydrargyri Ammonio-Chloridum.
Syn.—Mercurius Præcipitatus Albus,
Calx Hydrargyri Alba,
Hydrargyrus Præcipitatus Albus,
Hydrargyrum Præcipitatum Album.

The most unusual and least likely to be known amongst these is the calx hydrargyri alba, at one time frequently so written and still met with in old prescriptions.

Hydrargyri oxidum or hydrargyri oxidum cinereum is not in the B.P.; it is seldom now prescribed, but was formerly in ointment. Since writing this a prescription has been presented in which hydrargyri oxidum cinereum is ordered, the prescriber upon a second thought writing underneath black oxide, evidently under the impression that it might not be understood.

Name—Hydrargyri Binoxidum.
Syn.—Mercurius Calcinatus,
Hydrargyrus Calcinatus,
Hydrargyri Oxidum Rubrum,

was omitted in the B.P. of 1867, but has since been placed among the additions as hydrargyri oxidum flavum. It is now prepared by precipitation, employing a solution of perchloride of mercury and solution of soda in place of a solution of bichloride of mercury (former name) and solution of potash.

Hydrargyri nitrico-oxidum is now hydrargyri oxidum rubrum.

These omissions, alterations, and re-admissions are perplexing to those well versed in the matter,—must they not be more so to those not far advanced in pharmaceutical study? and therefore, as it appears to me, it is not out of season but desirable that attention should occasionally be drawn to them.

If prescriptions were never written but in accordance with the nomenclature of the B.P. then it would be needless to study synonyms except for the understanding of prescriptions written before 1867; but even that would, I think, be a sufficient reason for becoming acquainted with them. But who can say that the nomenclature now in use shall not be put aside when the establishment of a Universal or International Pharmacopœia takes place? The millennium of a permanent pharmacopœial nomenclature is yet far distant. Given, that all chemists agreed as to the names of the chemical portions of the work, what shall I say of the galenical?

Take for instance the simple preparation confectio rosæ caninæ, how many pupils of three years' standing would recognize it in conserva cynosbati,—a name much in vogue not long since, to be seen in many a cough linctus form, and a name quite within the range of possibility to be used again? Some prescribers prefer unusual names, so that patients may not know exactly what they are taking. Again, take emplastrum cantharidis, formerly known as emplastrum vesicatorium, and emplastrum epispasticum, the last word being rejected to designate the emplastrum in the B.P., but taken up to christen the blistering liquid, liquor epispasticus. If I were to go into the articles of the vegetable Materia Medica, or those in demand in a general pharmaceutical business, such as is found in many parts of London and all parts of the provinces, the subject of synonyms might be continued to a very considerable extent, more especially if the common English names given to some of the American preparations or remedies be mentioned, *e.g.*, Podophyllum peltatum (common names,—may apple, hog apple, raccoon berry, wild lemon, and mandrake), or Leptandria Virginica (common names,—black root, culver's root, culver's physic), etc. Again, Hydrastis Canadensis (golden seal, yellow puccoon, ground raspberry, turmeric root), etc. But enough I feel has been stated to make the matter worthy of inquiry and study.

If it be true, as has been said, that there have been those who did not know that hydrargyri oxidum and hydrargyri oxidum cinereum were synonymous, and that antimonii potassio-tartras was sought for on the shelf of the dispensing counter when antimonium tartaratum was full in view; that magnesia, magnesia levis, magnesiæ carbonas, magnesiæ carbonas levis, condensed magnesia and condensed carbonate of magnesia are a puzzle to many; then surely no apology is necessary for introducing the subject. If such sayings be fallacious there can still be little or no harm in jogging the memory upon synonyms.

LEAD IN HAIR RESTORERS.

BY JOHN C. HUNTER, A.P.S.

Pharmacists have generally looked upon "hair restorers" with some suspicion, former analyses having shown them to be more or less charged with lead.

A gentleman in Glasgow, otherwise in good health, was seized with partial paralysis of the tongue rather suddenly. His medical adviser on questioning him found that he had been using for his hair, which was turning grey, a hair restorer, and on the bottle being produced it was seen to be one well known in the trade. On the label it was stated that the "restorer" was perfectly harmless, being free from lead and other injurious ingredients. The patient's symptoms indicated a stage of lead poisoning, and the label on the bottle did not satisfy his medical man as to the harmlessness of its contents. He therefore caused some of it to be sent to me in a bottle, for examination, to ascertain if there were any lead present, and, if so, in what quantity.

I found the contents of the bottle to consist of a clear fluid portion, and a grey-white precipitate. On filtering off the clear fluid, and applying the usual tests for the presence of lead, it was found to be present in the proportion of 2·75 grs. in the fluid ounce, existing in the form of acetate.

On examining the precipitate it was found to consist of ·5 gr. lead carbonate, and 2·8 grs. sulphur in each fluid ounce of the hair restorer; therefore the total amount of the two lead salts was equal to 3·25 grs. in each fluid ounce of it, notwithstanding the statement on the label that the "restorer" contained no lead or any other injurious ingredient.

BENZOATE OF LITHIUM.*

BY E. B. SHUTTLEWORTH.

This salt has been proposed as a remedy for certain disorders of the urinary organs, and appears to possess advantages over the forms in which lithium has heretofore been exhibited. The comparative insolubility of the

* From the *Canadian Pharmaceutical Journal.*

carbonate has always proved a bar to its general employment, and though the citrate is in this respect much more eligible—only twenty-five parts of water being required for solution—yet the salt is of an unstable and deliquescent character, and somewhat troublesome to prepare and dispense. The benzoate is not open to any of these objections, and has the additional advantage of containing, in combination, an acid which is itself of no inconsiderable repute in the treatment of patients suffering from various forms of urinary deposits.

This salt is not usually to be met with in commerce, but is not difficult to prepare. I am not, however, aware of any work of reference which contains any directions or formula for this purpose; and am, therefore, induced to believe that a few remarks on the subject may prove acceptable.

Benzoate of lithium may be most advantageously prepared from the carbonate—

$$\underset{74}{L_2CO_3} + \underset{244}{2\,HC_7H_5O_2} = \underset{256}{2\,LC_7H_5O_2}$$

In a wedgewood dish put one ounce, avoir., of carbonate, mixed with nine ounces of water. Heat gently by aid of a spirit lamp, and add gradually, and by small portions, benzoic acid until effervescence is no longer produced. About three and a quarter ounces will be required. Evaporate to dryness, stirring constantly, and reducing the heat towards the close of the operation. The product may, for convenience, be powdered. The yield will be nearly three and a half ounces.

By following this process a much less quantity of water and consequently less evaporation will be needed than if the benzoic acid be dissolved and the carbonate added thereto. If, by reason of impurity or discoloration of the benzoic acid, it is necessary to filter the solution, three ounces more water may be added before evaporation; and, if required, a little purified animal charcoal may be used. The benzoate may be obtained in crystals by withdrawing the heat and setting the solution aside immediately after the benzoic acid is all added.

Watts* says the lithium salt of benzoic acid is uncrystallizable. This is incorrect; the benzoate may be crystallized without the slightest difficulty. It takes the form of glistening, pearly scales, or laminæ, somewhat resembling iodide of cadmium, but less lustrous. The crystals feel soapy or greasy to the touch; have a cool, sweetish, and not disagreeable taste, and are perfectly permanent in the air. The solution has an acid reaction.

I have found the salt to be soluble in three and a half parts of water at 60° F.; in two and a half parts at 212° F.; and in ten parts of cold alcohol, sp. gr. 838.

THE OCCURRENCE OF ORGANIC FORMS IN CONNECTION WITH CONTAGIOUS AND INFECTIVE DISEASES.†

BY J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

LECTURE I.

(*Concluded from page* 666.)

INFLUENCE OF BACTERIAL VEGETATION ON THE PROCESS OF PUTREFACTION.

In referring to Cohn's classification of the organisms which constitute the group of Schizomycetes according to their form, I stated that this classification was chiefly of value for the purposes of description, and that the exact similarity of any two forms cannot here be taken as evidence of their organic continuity any more than their dissimilarity affords indication of the absence of intimate relation between them; for the influence of environment over organisms such as bacteria is so great, that it seems as if it were paramount; the surrounding conditions claiming a power not merely of moulding the organism into conformity with themselves, but even of originating it.

For reasons on which it is unnecessary to enter here, we do not admit the latter part of this claim; but it is a principle of fundamental importance in dealing with the question we have now before us—that of the agency of bacteria in septic processes—that the influence of circumstance over form is practically so powerful, that, in considering the relation of bacteria to septic processes, we shall do best if we regard the appearance of particular forms as mere links in the chain of events of which the process consists.

To illustrate this, it will not be waste of time to refer for a moment to the singular fact discovered a short time ago by Professor Cohn, that, under conditions as yet quite unknown, colouring matters come into existence in albuminous liquids when left to themselves at ordinary temperatures; and that this development of pigment is associated with the development of bacteria. Not long ago, having left a "solution" of ordinary egg-albumen in a cupboard in the laboratory, I found that the liquid, which had no putrid odour, possessed an intense indigo blue colour. Being acquainted with Cohn's observations, I at once guessed what had happened, and found on microscopical examination, that the blue scum on the surface of the liquid consisted, first, of colourless bacteria, resembling in form those met with in septic liquids; and, secondly, of blue pigment particles of extreme minuteness, which appeared to be imbedded in the interstitial gelatinous material by which the organisms were surrounded. The process continued for some time, but eventually the liquid was inadvertently allowed to dry. On inoculating a similar albuminous liquid with the dried residue, I was unsuccessful in reproducing the process; but Cohn, who came upon several of his colour-producing bacteria in a similar accidental way, was able to perpetuate the process by repeated transmissions.*

I mention this observation merely to illustrate what I have been saying as to the relation between the two collateral processes—between the vegetation process on the one hand, and that of the formation of a characteristic chemical product on the other. Here we have no sufficient reason for saying either that the production of colour is the cause of the development of bacteria, or that the bacteria are the agents in the production of the pigment. All that we observe is, that the two phenomena begin, continue, and end together; we regard them, therefore, as collateral characteristics of one and the same process.

As the result of innumerable observations, we know that, as a rule, those changes in albuminous liquids, which we familiarly recognize as constituting putrefaction, are accompanied by the presence in such liquids of characteristic vegetable organisms. We also know that the two processes—viz., the chemical changes and the rapid vegetation go on *pari passû*, and that the same circumstances which favour the growth and multiplication of organic forms also favour putrefaction.

As to the meaning of these facts, there is some difference of opinion even among competent naturalists. All are agreed that the relation between the chemical process and the vegetative process is an intimate one; but somewhat discrepant views prevail as to its nature.

The fundamental experiment by which the intimacy of the association is proved is this. When a tube or flask is partly filled with water containing albuminous matter in solution or suspension, and subsequently boiled for a sufficient length of time, and closed hermetically during ebullition, no putrefaction occurs under any circumstances; but if, after such a tube has been heated and allowed to cool, a drop of distilled water, or any other exposed liquid, be added before the tube is again sealed, putrefaction follows, provided that the preparation is kept at the ordinary temperature.

As I have already hinted, there are some naturalists who would not agree to the terms in which I have stated

* 'Dict. of Chem.,' p. 552.

† Lecture delivered at Owens College, Manchester; reprinted from the *British Medical Journal*.

* Cohn, *loc. cit.*, p. 180.

this result. They would rather substitute for the words "under any circumstances" some such expression as "in 9,999 cases out of 10,000." For our present purpose, it makes little difference whether the statement be accepted absolutely or not. But there is another point relating to the origin of bacteria in albuminous liquids of much greater importance, which the discussion about abiogenesis is apt to conceal, or throw unduly into the background. It is a question which arises directly out of the results of the "cultivation" experiments to which I have just referred. These experiments show that bacteria are able to derive the whole of the carbon they require for the building up of their protoplasm from compounds of great chemical simplicity, which have never formed part of any living organism, and seek for no higher source of nitrogen than ammonia. This being the case, it is more than probable that, when the growth of bacteria goes on in association with septic processes, they derive their nitrogen and carbon, not from the albuminous compounds themselves, but from the ultimate products of their disintegration. This being the case, we must regard bacterial life (in so far as it consists in the building up of new protoplasm) as a process consequent on the chemical process of putrefaction with which it is associated. For disintegration must already have proceeded as far as to the production of ammonia—in a word, must have proceeded to the last stage—before the new integration could commence.

While admitting this, it is important clearly to see that the admission does not in any way render it more or less probable that bacteria are the efficient causes of putrefaction—that without which putrefaction could not take place—for there is nothing which forbids us to regard bacterial vegetation as connected (if I may so express myself) with both ends of the chemical process of disintegration of putrescible material at the same time; not the shadow of an objection to the assumption that, on the one hand, bacteria derive material for the integration of their protoplasm from the products of *dis*integration of the soil in which they flourish, and on the other, that they produce the ferment by which disintegration is determined. There is nothing, in short, against their standing to the chemical process at the same time in the relation of antecedent and consequent.

If it should seem to you that this is a too vague way of dealing with the subject, I would ask you to consider that the question is one in respect of which caution is more than usually necessary; for, while theoretical explanations offer themselves freely on every side, experimental investigation is beset with peculiar difficulties. As regards the main question, that of the agency of bacteria in producing putrefaction, there are two extreme views, which are both clearly mistaken—the one which asserts that they have nothing to do with the septic process; the other, that the chemical phenomena of putrefaction are the mere accidents of a peculiar kind of vegetation. The truth lies without doubt between these two opposed theories; but it is not to be got at by an ingenious reconciliation of the one with the other, but by honestly opening the minds to the facts as they stand, in the confidence that, if they are allowed fair play, they will eventually shape themselves into a general conception, in accordance with their true relation. So long as uncertainty exists, there is nothing to be so much avoided as that sort of clearness which consists in concealing difficulties and overlooking ambiguities.

[Since this lecture was delivered, an important contribution to the elucidation of this question has been made by Dr. Hiller of Berlin (*'Der Antheil der Bacterien am Fäulnissprocess,' Centralblatt*, No. 54, Nov. 14th, 1874). Starting from the fact observed by himself (to the accuracy of which I can testify from my own observation) that, in the "alkaline fermentation" of urine, the splitting of urea into ammonic carbonate is not in relation with the abundant development of septic bacteria in the liquid, he made experiments which showed that in urine, bacteria do not derive their nitrogen from urea, but from other sources; and that, if ammonic tartrate be added to urine the multiplication of bacteria goes on with great activity, without any diminution of its acid reaction, *i.e.*, without any decomposition of its urea. From this result, he proceeds to similar experiments as to the influence of bacteria on egg-albumen. Having first ascertained, by careful observations, the fact familiar to the housewife that fresh eggs "turn" when put into the same basket with rotten ones, and can therefore be infected through the air, he injects a "cultivation liquid," containing bacteria, but not putrid, into the albumen of a fresh egg, with the aid of a subcutaneous syringe. The egg remains unaltered. He therefore thinks it impossible to identify multiplying bacteria with the "septic ferment"; with reference to which he thinks that the experimental investigations of the last few years have proved nothing more than "it is a particulate substance which either exists suspended in the air, or adheres to objects, and that it can be separated from the air by filtration, and can be destroyed by the temperature of ebullition." With this final statement of the case I perfectly agree, and am not at all disposed to quarrel with him because he goes on to suggest that the "particles" of which the septic ferment consists are not living beings, but *Protëinsplitterchen.*]

THE CARBONYLS, AND THE TRUE FUNCTION OF ORDINARY CAMPHOR.*

BY M. BERTHELOT.

The author proposes to institute as a new class of organic compounds, a subdivision having the general function of aldehydes, to which he proposes to give the name of carbonyls. It comprehends at present three well defined bodies, of which it systematizes the reactions. These are—ordinary camphor; oxide of allylene, or dimethylene carbonyl, discovered by the author a few years since; and the diphenylene carbonyl, obtained by the oxidation of fluorene, and designated under the name of diphenylenacetone by Fittig and Ostermayer.

Oxide of Allylene or Dimethylene Carbonyl† .	$C_6H_4O_2$ or $(C_2H_2,\ C_2H_2)\ C_2O_2$
Diphenylene Carbonyl .	$C_{26}H_8O_2$ or $(C_{12}H_4, C_{12}H_4)C_2O_2$
Camphor, or Terebutylene Carbonyl . . .	$C_{20}H_{16}O_2\ (C_{10}H_8,\ C_8H_8)\ C_2O_2$

Suberone ($C_{14}H_{12}O_2$), the author thinks, probably has a similar constitution.

These bodies, he considers, may be regarded as the types of homologous series, and of a great number of other compounds possessing the same characteristic reactions, which he describes as follows:—

(1) The carbonyls can fix hydrogen and become changed into alcohols; reciprocally the alcohols so engendered reproduce carbonyls by the loss of hydrogen.

$C_6H_4O_2 + H_2 = C_6H_4(H_2O_2)$ . . Hydrate of Allylene.
$C_{20}H_{16}O_2 + H_2 = C_{20}H_{16}(H_2O_2)$. Campholic Alcohol.

This general reaction is that which has been proposed by the author to characterize the aldehyde function; it includes the true or primary aldehydes, the secondary aldehydes or acetones, and the aldehydes having a mixed function, such as the quinones.

(2) Carbonyls can be formed directly or indirectly by the substitution of equal equivalents of oxygen for hydrogen in incomplete carbides:—

$C_{2n}H_{2(n-p)}H_2(-)$ forms	$C_2H_{2(n+p)}O_2(-)$
Propylene, $C_6H_4,H_2(-)$ forms thus .	$C_6H_4O_2(-)$
Hydride of Camphine, $C_{20}H_{16},H_2(-)$ forms	$C_{20}H_{16}O_2(-)$
Fluorene, $C_{26}H_8,H_2(-)$ forms . . .	$C_{26}H_8O_2(-)$

They can also be formed directly by oxidizing with chromic acid the still more incomplete carbides which are derived from the foregoing by loss of hydrogen.

Allylene, $C_6H_4+O_2$, forms	$C_6H_4O_2$
Camphine, $C_{20}H_{16}+O_2$, forms	$C_{20}H_{16}O_2$

* *Journal de Pharmacie et de Chimie* [4], xxi., 81.
† C = 6; O = 8.

These two modes of synthetic formation are analogous to those which are observed in the study of the aldehydes properly so-called and the secondary aldehydes or acetones. In fact, by direct oxidation by means of pure chromic acid the author has found that—

Ethylene, $C_4H_4 + O_2$, forms $C_4H_4O_2$: Ethylic Aldehyde.
Propylene, $C_6H_6 + O_2$, forms $C_6H_6O_2$: Acetone (and Propyl Aldehyde at the same time).

On the other hand, by indirect oxidation—

Hydride of Ethylene, $C_4H_4(H_2)$ forms . $C_4H_4(O_2)$.
Hydride of Propylene, $C_6H_6(H_2)$ forms . $C_6H_6(O_2)$.

But the carbides which engender the aldehydes proper and the acetones, by this latter substitution, are saturated compounds, whilst the carbides that engender similarly the carbonyls, are incomplete: this is an essential difference, which leads to important consequences in their reactions. The carbonyls, in fact, are themselves incomplete bodies, and that independently of their aldehyde function. Besides their aptitude to change into alcohols by hydrogenation, like aldehydes in general, the carbonyls present the special character of fixing by addition the elements of water, and, in principle, all other simple or compound bodies occupying the same gaseous volume.

(3) It is thus that the fixation of the elements of water changes the carbonyls into monobasic acids; it is similar to the fixation of water upon carbonic oxide by which formic acid is formed, and is effected in the same manner by the aid of alkalies.

C_2O_2 [–] + $H_2O_2 = C_2H_2O_4$. Formic Acid.
$C_{20}H_{16}O_2$ [–] + $H_2O_2 = C_{20}H_{18}O_4$. Campholic Acid.
$C_{26}H_8O_2$ [–] + $H_2O_2 = C_{26}H_{10}O_4$. Diphenyl Formic Acid.
$C_6H_4O_2$ [–] + $H_2O_2 = C_6H_6O_4$. Propionic Acid.

(4) In virtue of the same incomplete character, the carbonyls can be changed into bibasic acids by the fixation of 6 equivalents of oxygen:—

$C_{20}H_{16}O_2$ [–] + $O_6 = C_{20}H_{16}O_4,O_4$. Camphoric acid.
$C_6H_4O_2$ [–] + $O_6 = C_6H_4O_4,O_4$. Malonic acid.

This fixation may be interpreted in two ways; either that the camphor fixes at first O_2, in the manner of ordinary aldehyde, which becomes acetic acid, and that the incomplete character of the camphor would render it able to fix O_4 additional; or that the camphor tends to form at the first the two acids $C_2H_2O_4 + C_{18}H_{14}O_4$, according to the type of the oxidation of acetone, which gives rise to $C_2H_2O_4 + C_4H_4O_4$. But the two acids derived from camphor would combine together in the nascent state in consequence of the incomplete character of one of them.

(5) Carbonyls can be formed analytically by means of a single molecule of a bibasic acid, by loss of water and carbonic acid. This mode of formation recalls the acetones; but they are derived from two distinct molecules of monobasic acid which assigns to them a very different constitution, especially in view of the incomplete character of the carbonyls.

The author claims that the theory put forth by him is based upon the relations of facts, independent of all hypotheses respecting the internal constitution of carbides, aldehydes, or acids; but that it is easy to connect it with what is known of the formation of carbides themselves, without need of having recourse to radicals or even a particular symbolism.

All the carbides can be derived from formene by the successive union of that carbide to a first molecule of formene with separation of a volume of hydrogen equal or superior to that of the formene which enters into combination. The aldehydes (aldehydes proper, acetones, and carbonyls) result from the substitution of equal equivalents of oxygen for hydrogen in the carbides. It may be admitted that the aldehydes result from the oxidation of a certain molecule of formene; but their properties should vary according to the number and nature of the reactions previously accomplished upon the molecule of formene which gives them birth.

The author hopes that the institution of the class of carbonyls will put an end to controversy respecting the real function of camphor. He thus recalls the history of this question. In 1840 Pelouze discovered that ordinary camphor could be obtained by oxidizing Borneo camphor; but he took care to declare expressly that he refused to accept either the theory that looks on Borneo camphor as an alcohol or that which regards it as a hydride of camphor; the relation between the two bodies, in his opinion, not being closer than that which exists between oxalic acid and the organic matters which yield oxalic acid when treated with nitric acid. In 1859 the author, during his researches upon saccharine principles and etherification, discovered by direct synthesis the combination of Borneo camphor with acids, and demonstrated that it fulfilled the function of an alcohol. Hence it became probable that in respect to it ordinary camphor played the part of an aldehyde, and he succeeded in effecting the synthesis of Borneo camphor by the hydrogenation of ordinary camphor, and ascertained that a camphor isomeric with ordinary camphor could be obtained by oxidizing crystallized camphine.

The author, however, distinguishes camphor from the aldehydes, properly so called, by the fact that its direct oxidation does not furnish a monobasic acid, comparable to acetic acid; and from the acetones by its oxidation yielding a single bibasic acid, without breaking up into two distinct acids, comparable to the two derived from acetones. The aptitude of camphor to fix the elements of water and become converted into a monobasic acid, also differs from the properties of acetones. So long as camphor appeared to stand alone the author hesitated to make it the type of a new class of compounds; but since the discovery of new bodies possessing analogous reactions has cleared up apparent anomalies, he considers himself justified in establishing a new class of aldehydes, which he proposes to call carbonyls.

NORWICH CHEMISTS' ASSOCIATION.

Some four years since, the chemists' assistants and apprentices in Norwich formed an association for the purpose of aiding them in the acquisition of the necessary technical knowledge to enable them to pass the Minor and Major examinations of their profession. Classes were instituted and much good resulted from them. Last year a more comprehensive character was given to the Association by the admission of principals to full membership, and by its re-construction under the above title. It has received a grant from the Pharmaceutical Society of Great Britain, and, besides placing at the service of the members a library and museum, it offers the advantages to be derived from class studies, under competent teachers, of chemistry, botany, and materia medica. All that is required is increased support to enable it fully to accomplish the object for which it is established. One of the principal founders of the Association, and its late president, Mr. Nuthall (assistant to Mr. F. Sutton), being about to leave Norwich, having taken a business in the county, the members, in his honour as well as for the good of the society, instead of a private annual dinner among themselves, gave a semi-public dinner at their rooms in Duke's Palace, on Thursday evening, February 18, which was exceedingly well attended, covers being laid for fifty gentlemen. The chair was occupied by Mr. Corder, the president. Mr. W. K. Cooke (vice-president) filled the vice-chair. After the usual loyal and patriotic toasts,

The President said he had great pleasure in proposing the health of his friend Mr. Nuthall, and only regretted that this was the first, and he was afraid might be the last, time he should have that pleasure. Mr. Nuthall had been amongst them for many years, and, so far as that association was concerned, there was no man who had done so much, so well, and so heartily, for it; and if any one had not passed his examination, or acquitted himself so well as he should have done, the fault did not rest with Mr. Nuthall. In leaving them, the members would, he was sure, wish him every success in his undertaking, with health and prosperity.

Mr. Nuthall said what he had done for the society had been a pleasure to him, and he only regretted that recently it had not met with more support from that class for whom it was particularly intended—the apprentices. Since the Association had been in existence he had always met with every assistance from the employers who were members, and also from the more advanced of the students who had succeeded in passing their examinations; but when he turned to what should be the apprentices' class he found a coldness difficult to account for, but which he hoped that meeting would do something towards breaking down. He hoped that the employers present would endeavour to create among their apprentices and assistants a greater warmth in pharmaceutical study and education, and also direct their attention to this society as a means of acquiring the same. One of the things that caused him much regret in leaving Norwich was the breaking of his connection with this society. He had been associated with most of the members, either on committee or as a teacher, for four years, and he assured them it was with the deepest regret that his connection with them would now be severed. But wherever he should be the Association would have his best wishes, and he hoped at times to be able to come amongst them.

Mr. Pitts, in giving "Prosperity to the Pharmaceutical Society of England," spoke of the giant strides that Society had made in the country, and the advantages now enjoyed by young men compared with those of thirty or forty years ago, when the hours of business were much longer. He hoped these advantages would be turned to the best account, and that the chemists of the next generation would make better men than those of the present and the past. With the toast he coupled the health of Mr. Cubitt, the first Local Secretary to the Pharmaceutical Society.

Mr. Cubitt responded. He said that sixty years had passed since he made his commencement in business, and although he should himself never be a partaker of the benefits of the Pharmaceutical Society, he could see plainly and clearly that it would be a great boon to those who availed themselves of it. He called attention to the advantages now enjoyed by chemists' apprentices and assistants compared with the state of things years ago, and dwelt upon the importance of pupils acquiring in addition to a mechanical knowledge of their business an accurate knowledge of accounts, which at present many of them were unacquainted with, thus falling into difficulties which otherwise they might steer clear of.

Dr. Pitt, in acknowledging the toast of "The Medical Profession," said he believed the medical profession had always been on very good terms with this society and with all chemists. From his own knowledge he was able to say that chemists had been a great assistance to medicine, and he believed he might add that medicine had been a great assistance to them. As secretary to the British Medical Association at its meeting in Norwich, he had the greatest pleasure in affording them a good opportunity of exhibiting their specimens in chemistry and materia medica, and it was a source of pride to the medical profession to have such an exhibition in connection with that society. As a body, he believed there existed great unanimity of feeling both among medical men and chemists, and without that kindness of feeling they would not be able to get on as they did.

Dr. Beverley endorsed what Dr. Pitt had said, more especially with regard to what he trusted would always be an intimate connection between the calling of the chemist and the doctor; because for the good working of either there must always be unanimity of feeling between the medical profession and that of the pharmaceutical chemists. He was glad to find that in both professions alike they were advancing with rapid strides. At one time, many years ago, any man could practise the profession of a surgeon, or even of a physician, without passing an examination, and the same unsatisfactory state of things existed with regard to chemists; but now, he was glad to say, no one could deal in drugs without having his knowledge tested by a practical examination. The members of both professions were servants of the public, and the public had a right to expect from them that knowledge which could only be secured by practical examinations. Dr. Beverley having expressed his satisfaction at learning from the President that the pharmaceutical examination was a very practical one indeed, proceeded to express his concurrence with what fell from Mr. Nuthall as to the very few members attending the classes in this room. He regretted this, because he had seen the table covered with some very beautiful specimens, and had listened with great interest to one gentleman dissecting plants and teaching a botanical class as carefully and accurately as he (Dr. Beverley) was taught himself; and it was a pity that the medical students of Norwich were not present to hear him. In conclusion, he hoped with this inauguration dinner the Association would enter upon a more satisfactory state of things, and that, although they were losing the valuable assistance of Mr. Nuthall, they would, one and all, put their shoulders to the wheel and carry on the Association with more vigour than hitherto.

Mr. Thompson proposed "The Health of the President of the Association and one of the Examiners of the Pharmaceutical Society." Mr. Thompson, in the course of some practical observations, urged upon apprentices the importance of not deferring their studies till they were assistants.

The President (Mr. Corder) acknowledged the compliment. He said that since he had been on the Board of Examiners, in London, the young men who had come up from Norwich, who had studied in this Association, had all, with one exception, passed the examination. This showed the use of these associations, if only they were properly attended. Young men who came up from these associations were better prepared than those who studied in London, and it only stood to reason that three months "cram" in London could not possibly make up for four years wasted in the country. Not only was it important to the profession of pharmaceutical chemistry that the examinations should be passed, but the medical profession and the public expected that the chemists and druggists of the present day would advance as every other profession was advancing. Our chemists and druggists were far below those of the continent, for in France, Germany, and Italy the examinations were much more stringent, and it was impossible for a man to enter the business unless he passed those examinations. He trusted this Association would not die out, but would have more vigour as time went on, and that young men who wished to take a position in business would see that study must be made, and that they must not blame the Pharmaceutical Society or the examiners if they did not pass the examinations, which were well and properly conducted. He (the President) much regretted that their Local Secretary, Mr. F. Sutton, was unable to be present. His absence was not owing to any lack of sympathy, but to his having been unexpectedly called away that day to attend a council meeting of public analysts.

After the health of the Vice-President had been drunk, Mr. Woodhouse proposed "The Norwich Chemists' Association.

Mr. Butler, the treasurer, in returning thanks, spoke upon the numerical and financial condition of the Association; both of which, he said, required improvement. The subscription was only 10*s*. a year, and although there was a balance in hand the state of the funds would have been different but for their science and art classes in connection with South Kensington. As the President had said, those who had gone up from the Association to London had been successful with one exception, and some of them had obtained honours. He suggested whether it would not be possible to extend the Association to the county and thus make it "The Norfolk and Norwich Chemists' Society."

Mr. T. Pitts (the secretary) also acknowledged the toast. Several other toasts were subsequently drunk.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 27, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PROSPECTS OF PHARMACY IN IRELAND.

AT the moment of going to press, we learn that, in addition to the Bill which Sir MICHAEL HICKS BEACH has announced that it is the intention of the Government to bring in during the present session with the object of regulating the practice of Pharmacy in Ireland, there is a probability that at least another Bill on the same subject will be introduced into Parliament. According to a communication we have just received from Dublin, a deputation from the Society of Chemists and Druggists of Ireland has recently waited on Sir DOMINIC CORRIGAN, in reference to the subject of pharmaceutical legislation for Ireland, and a special meeting of the Society was held last Tuesday evening for the purpose of receiving a report from the deputation. The President, Mr. E. M. HODGSON, said that the deputation was cordially received by Sir DOMINIC, and that the matter in question w[illegible] [illegible]lly discussed. The opinion of Sir DOMINIC was that the subject would be taken up in the present Parliament, and so far it is in accordance with the announcement that appeared last week in our paper,* as well as in most of the daily and weekly papers. Sir DOMINIC also expressed the opinion that if the ranks of pharmacists in Ireland were to be augmented, it must be from the body of chemists and druggists. In this respect, also, we are happy to find that the views we have from time to time put forward on the subject of Irish pharmacy are in accordance with those of Sir DOMINIC CORRIGAN.

According to our judgment nothing can be more appropriate or more consistent with the spirit of the age than the severance of pharmaceutical from medical duties as well in Ireland as in this country. We believe that this opinion will be generally shared not only by those who think on what is good for the interests of pharmacy, but that it would also be admitted as correct by those who are still subject to the trammels of habitual usage which had led their practice in the opposite direction before they had opportunity of considering both sides of the question, provided they would give due attention to the matter. The realization of this object will, however, be a work of time; but it may be materially facilitated by legislative action, and we still hope that it will receive that aid.

* See *Pharm. Journ., ante,* p. 67

We have always held, moreover, that it would be highly conducive to the interests of the public at large, as well as of pharmaceutical practice, if the obsolete *régime* of the Apothecaries' Hall of Ireland, in regard to pharmacy, were superseded, and if the competently qualified chemists and druggists of the sister country were permitted to perform the functions they are well able to perform, in dispensing medicines with advantage to themselves no less than with convenience to the public. The dearth of provision for the requirements of the public in this respect seems unquestionable, for it is unequivocally admitted by all parties, and we see no other means of providing for the deficiency than the removal of those disabilities which now prevent the educated chemist and druggist from doing the work he is well able to do.

Sir DOMINIC CORRIGAN seems to hold similar opinions, and consistently enough he recommended the Society of Chemists and Druggists in Ireland to draw up a Bill and ask the Government to introduce it. Nothing could be more fitting than that those who suffer under the legal disqualification for practically carrying out the main part of their business should undertake the task of drafting a measure by which they should be relieved from this unjust restriction. We heartily concur with Sir DOMINIC's further recommendation that Irish pharmacists should act independently in this matter by establishing an independent Irish Pharmaceutical Society or College of Pharmacy, complementary to the existing Colleges of Physicians and Surgeons, and we have nothing to urge against the opinion he expressed that Irel should have its own Pharmaceutical Society.

In the endeavour to attain this object Irish Pharmacists would have the advantage of the example that has been set by their brethren in Great Britain; we have every desire to see them soon actively at work in this direction, and we wish them all success in their labours.

As a first step we may record that at the meeting last Tuesday in Dublin, a resolution was passed on the motion of Professor TICHBORNE, seconded by Mr. STANLEY OLDHAM, that Messrs. E. M. HODGSON, Professor TICHBORNE, WM. HAYES, J. GOODWIN, W. ALLEN, A. DORAN, STANLEY OLDHAM, and R. SIMPSON, should form a Committee to frame a Bill and submit it to Sir DOMINIC CORRIGAN for his opinion and advice.

THE ADULTERATION BILL.

THERE can be little doubt if the Bill now before the House of Commons should become law without much alteration, that it will be effectual in repealing the existing Act, and will not leave much room for complaint on the part of the retail dealer. But whether it would in the same degree provide better for the sale of food and drugs in a pure state does not seem so evident. To judge from the speeches of some honourable Members last Friday, it would seem that there will be considerable opposition to the Bill in Committee, and we look forward with interest to the discussion of its several clauses. We trust, however, that legislation on a subject of so much importance to the general public and to traders may not be influenced by such out-of-date statements as were put forward in the discussion last Friday. We refer more especially to Dr. PLAYFAIR'S remarks as to the practice of drug-grinding which have called forth repudiations from several wholesale druggists and drug-grinders. We are surprised that Dr. PLAYFAIR'S usual shrewdness and caution should have been got the better of by a mere piece of antiquarian scandal, which we have every reason to believe has long ceased to have any application, thanks to the improved system of education that has been introduced during the last twenty years. We are, however, glad to note that Dr. PLAYFAIR endorsed Mr. PELL'S objections to the ridiculous fees proposed to be paid to analysts. As a distinguished chemist, no less than as a Member of Parliament, he had a special right to speak dogmatically on this point, and, in doing so, he honourably acquitted himself of a duty he owed to the followers of a profession to which he has himself belonged. If the public good requires the services of chemists as analysts, the remuneration of such services should be sufficiently ample to ensure competent skill and due care on the part of the analyst, so that while the public is well protected the trader shall not be unduly prejudiced.

IMPORTANT LEGISLATION RESPECTING PHARMACY IN CANADA.

RECENT advices from the Dominion show that there is a probability of pharmacy in Upper and Lower Canada soon being regulated and protected by legislation equal in stringency to that existing on the subject in any part of the world. In the province of Ontario, pharmacy is at present regulated by an Act, passed in 1871, an abstract of which has been given in this Journal.* This Act having been found defective, an attempt was made during the last session of the Ontario Legislature to modify some of its provisions, but without success, principally in consequence of the opposition of the medical profession to a proposition to repeal that section of the present Act which gives to the members of the College of Physicians and Surgeons the right to carry on the business of a chemist and druggist without registration. The Bill is, however, to be brought forward again, and it is hoped that the misunderstanding which gave rise to this opposition will be removed.

Another important feature of the proposed Bill is, that it renders compulsory the passing of an examination and connection with the Ontario College of Pharmacy previous to entering the respective stages of "apprentice," "assistant," and "pharmaceutical chemist." The "apprentice," before the term of his indenture commences, is to produce to the Registrar a certificate showing that he has attained a creditable degree of proficiency in the subjects of examination for admission of pupils to high schools or collegiate institutes, or else he must pass a "Preliminary" examination settled by the Ontario College. Further, he is to pay annually the sum of one dollar to the Registrar, which is to entitle him to receive the Journal and Proceedings of the College. Before entering on the duties of an "assistant," the "apprentice" is to present satisfactory evidence of his having served a term of three years' apprenticeship, and to pass a "Minor" examination, for which he is to pay a fee of four dollars. He will then be entitled to registration as an "Associate" of the College, and be considered qualified to dispense the prescriptions of legally qualified practitioners conditionally upon his paying annually the sum of two dollars to the Registrar. An "Associate" desirous of being registered as a Member of the College, or of commencing business as a "pharmaceutical chemist" (the only class entitled under the present Act to carry on the business), must pass a "Major" examination, for which he is to pay a fee of four dollars, and is to pay a further fee of four dollars annually as long as he carries on the business of a pharmaceutical chemist. The right to registration of persons engaged in the capacity of apprentices or assistants at the time of the passing of the Act is provided for, and, after a certain date it is to be unlawful for any person carrying on the business of a chemist and druggist to employ in such business an apprentice or assistant who has not been registered under the Act.

A clause specially interesting to British pharmacists enacts that persons holding the diploma of the Pharmaceutical Society of Great Britain, the Pharmaceutical Association of Quebec, or the Philadelphia College of Pharmacy, and all persons registered under the Pharmacy Act of Great Britain, 1868, are to be entitled to registration as members of the Ontario College of Pharmacy without undergoing examination.

In the province of Quebec, the regulation of pharmacy has been for some time in a very unsatisfactory state, in consequence of it having been vested in the hands of the College of Physicians and Surgeons, and the opposition by the College to fresh legislation on the subject. According to the *Canadian Pharmaceutical Journal*,* however, a hastily drafted Bill, based upon the Ontario Act, and embodying the above amendments, has recently been passed rapidly through the Legislature and become law. The three grades in Quebec are to be termed "apprentices," "certified clerks," and "licentiates in pharmacy."

* See vol. i. (1870), p. 21.

THE SCHOOL OF PHARMACY.

THE courses of lectures on chemistry and pharmacy, and materia medica and botany, in connection with the Pharmaceutical Society's School of Pharmacy, Bloomsbury Square, will recommence on Monday, March 1st. Students who have but a limited time at their disposal would find the ensuing five months to be a very favourable time for studying at the School; for between the 1st of March and the 31st of July, they would have the opportunity of not only attending in the laboratory, and at the usual courses of chemistry and pharmacy, and botany and materia medica, but also the summer course of systematic and practical botany, at the Royal Botanic Society's Gardens, in Regent's Park.

AT the meeting of the Committee of the Chemists' Ball, held on Monday last, it was decided to hand over to the Benevolent Fund of the Pharmaceutical Society the sum of Twenty Guineas.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

On Wednesday evening, the 17th inst., a *soirée* was given by the Council of this Association to the members, in the Rooms, Music Hall, Surrey Street. The President, Mr. G. A. Cubley, in the chair. After the covers had been removed, "The Queen" was given by the chair, and duly honoured.

The President in announcing that the annual meeting would then be held, said that he could not congratulate the Association on the progress it had made during his year of office, but from the meeting that night and the support lately offered to them, he had no doubt that under the rule of his successor their affairs would take a brighter turn. It was especially necessary that they should be a united body, so that they might defend the interests of the trade, and again take up the question of education at a favourable opportunity.

The Honorary Secretary, Mr. E. R. Learoyd, read the report for the past year, which was of a somewhat discouraging character, showing an apparent decreasing of interest exhibited by the young men in attending the classes formed under the auspices of the Association, but a hope was held out that a want may arise which will result in the formation of regular classes and scholarships.

The Treasurer having given a statement of accounts for the past year, it was proposed by the Chairman and seconded by Mr. W. V. Radley, that Mr. H. W. Maleham should be President for the ensuing year. This was unanimously carried.

The President elect, having taken the chair, gave the following address to the members present:—

"Gentlemen,—The honour you have been pleased to confer upon me by electing me as your president is another proof of the confidence you have invariably placed in those who since the foundation of this Association have strenuously endeavoured to promote its welfare and prosperity, and through its operations benefit the trade generally in this town and district. It is, however, with very mingled feelings that I accept such a responsibility, and I feel sure in giving me your votes this evening, you deeply sympathize with me in thus being placed in the unfortunate and unenviable position of president of an Association neglected and maligned by those who ought to feel most interested in its welfare, and its very existence in such jeopardy as to cause the Council gravely to consider whether the Society should cease to exist, or another effort be made to fan the flickering flame into increased vitality.

"I am not prepared to give you an elaborate inaugural address; inability and the state of the Association will not permit of it, but I would take this opportunity to appeal earnestly to those who by their apathy have reduced the Association to its present position. Possessed of an able and devoted Council, a hard-working and zealous Secretary, and every appliance for the successful working of an institution like this, we only want the sympathy, personal co-operation, and pecuniary assistance of every principal and every assistant and apprentice in this town to render the Sheffield Pharmaceutical and Chemical Association second to none in the kingdom. It was formed at a time when legislation closely affecting our interests, both beneficially and otherwise, was rife, rendering it highly important that as provincial chemists we should raise our powerful voice against oppressive measures, and assist by our support the successful carrying out of those most conducive to the preservation of our rights and interests, and the elevation of our body to a higher standard. This Association was therefore formed, as were many others throughout the country, for this object, to promote education and conduce to mutual goodwill. I am happy to say we *have* done good, we *have* made our voice heard, notwithstanding those who have decried our usefulness and held themselves aloof from us. We have spent much time and money in supplying our apprentices and assistants with means, in the nature of library, lectures, and classes, for preparing for those examinations which are the tests of their fitness to take upon themselves the responsibilities of masters of establishments, and though it has pained us to see these opportunities disregarded and neglected in a great degree, I feel sure I am speaking the sentiments of my brethren of the Council as well as my own, in saying that the time and money has not entirely been thrown away, and that there are young men in this town and neighbourhood who would gladly testify to the advantages they have derived from this Association. I am not at all disposed to lay the entire blame upon the young men themselves. If masters have been blind to the benefits and privileges of an organization like ours, and by their absence from our meetings and deliberations shown little encouragement to those in their employ, it cannot be surprising the latter should be careless and indifferent. By the gradual withdrawal of subscriptions, as the reports from year to year have testified, they have withheld from us the means of cheapening the price of education, which in this town is very costly, to those who are disposed to do their utmost to deserve and appreciate it. Unquestionably the gauge of prosperity must be looked for in the subscriptions and fees, and as I have already stated, under this head there has been a great falling off. Why is this? We issue annual reports that I fear are more frequently thrown into the waste paper basket than read, or it could not be so frequently thrown into our teeth,—What are you doing for us? My answer has always been, Read the report, and come and see for yourselves. We are charged with not taking measures to prevent unqualified men from selling poisons and dispensing drugs. Our answer to this is, the Council is zealously working in that direction, and has already done much to put a stop to such practices, and though we may all individually do much, it is only organized bodies like this that can effectually deal with such a difficult matter. Then there is the early closing question. We are charged with neglecting that. We are all too much interested to permit this society to do that. If there were the slightest chance of any good coming from its interference, no one more than myself would wish to see the hours of business curtailed and labour lessened, but I am strongly of opinion that it does not come within the province of the Association. Nothing would be more calculated to bring discord amongst us, or interfere with our usefulness in other ways. We may each do much by example in our neighbourhoods, but I am sure it is quite out of character, in a large town like this, for residents in one quarter to attempt to legislate for those in another. Gentlemen, I have given you a very discouraging sketch of our position, but I trust better times are in store for us; there never was a period in our history when the existence of our society was of such importance to us as the present. An Adulteration Act is now in force, and from the differences of opinion existing amongst analysts as to what really constitutes adulteration of drugs, it acts very oppressively, and much vexation and injury has been experienced by chemists in different parts of the country by proceedings being taken against them on the most frivolous grounds. I am not inclined to dispute the existence of such abuses as adulterations, nor of the importance of enactments being in force to suppress them. Fortunately for us in Sheffield we have experienced much immunity from such annoyances as the Leeds "Milk of Sulphur" cases and others of a similar nature, owing to the intimate knowledge our borough analyst has of drugs and the customs of the trade. But our time may come notwithstanding, for although we may ourselves test in some measure the quality of our drugs, we must place a certain amount of confidence in the wholesale houses,—and what could be a greater comfort than to have an association like this to take up our defence? Undoubtedly, if it has the means, it ought to lend a helping hand to its members in such sore strait. I, therefore, in the name of the Council, appeal to you who have seceded from us, and you who have not yet joined us, to come forward at once, and with your subscriptions and personal support assist in keeping this Association together, and performing the work that is laid out for us. In conclusion, gentlemen, I thank you for the honour you have done me this evening, and taking my predecessors as models, I trust I shall merit the confidence you have placed in me, and that, when I vacate this chair, I may be able to congratulate you upon the prosperity of this Association, and that I shall see around me faces that have long been strangers to this room. Since arriving here this evening, I have been pleased to learn that the result of the canvass in the different districts by the members of the Council, has resulted in a considerable addition to our numbers, and in congratulating you, I do hope we shall put our shoulders to the wheel, and make it the most successful year we have ever had."

After a vote of thanks had been accorded to Mr. Cubley for the efficient manner in which he had filled the office of President for the past session, and duly responded to, Messrs. Ellinor and Jervis were elected Vice-Presidents, and after a vote of thanks had been given to the retiring Council and other officers, the following gentlemen were elected as Council for the ensuing year:—Messrs. Cubley, Ward, Learoyd, Cocking, A. J. Appleton, Hudson, Dunnill, and Otley; after which Mr. Radley was re-elected Treasurer. On the motion of Mr. Cocking, Mr. J. H. D. Jenkinson was elected Honorary Secretary in the room of Mr. Learoyd who for several years has successfully held that office. A vote of thanks having been given to Mr. Learoyd for his services and suitably replied to, Messrs. Priestley and Crawshaw were elected Auditors for the coming year. During the meeting a general discussion took place on the advisability of forming a trade protection section for mutual assistance in case of unjust prosecution under the Adulteration Act, also upon the desirability of a greater uniformity of charges being adopted for prescriptions and for the higher drugs and chemicals. These subjects were referred for full discussion at a future meeting. The President announced that Mr. Ward, F.C.S., would read a paper at the next monthly meeting of the Association. Fifteen gentlemen were proposed as members of this Association, which brought to a close a very successful and agreeable meeting.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 18th February, 1875. Professor Odling, F.R.S., in the chair. The minutes of the previous meeting having been read, Professor Clerk Maxwell delivered a lecture "On the Dynamical Evidence of the Molecular Constitution of Bodies." The lecturer, after some preliminary remarks, proceeded to discuss the dynamical method of studying a system of molecules, with especial reference to that elaborated by Clausius, showing how it would explain the variations from Boyle's law observed in dense gases. He then deduced from the kinetic theory that the number of molecules in a unit of volume of two gases must be the same, which coincides with Gay Lussac's law of equivalent volumes. The difficulties which at present beset the atomic structure of the molecule were then stated, as also those connected with the transparency of gases and their electric phenomena. After a vote of thanks to the lecturer the meeting was adjourned until Thursday, 4th March, when there will be papers "On Some Constituents of the Brain," by Dr. Thudicum; "On the Dissociation of Nitric Acid," by P. Graham and J. W. Gatehouse; "On Calcic Hypochlorite from Bleaching Powder," by C. Kingzette; and "On a Simple Method of Determining Iron," by W. Noel Hartley. The Faraday lecture "On Liebig's Contributions to Experimental Chemistry," will be delivered on Thursday, 18th March, by Dr. A. W. Hofmann, F.R.S.

PHILADELPHIA COLLEGE OF PHARMACY.

The fourth meeting of the session was held January 19th, 1875, Dr. Wilson H. Pile in the chair. The minutes of the previous meeting were read and approved.

Professor Maisch, from the collection of the late Professor Procter, presented *Penghawar Djambi*, portions of the stipes, with the hair-like chaff still attached, of ferns from the East Indian Islands, the hairs being used as a hæmostatic, acting mechanically; also, from Dr. J. W. Eckfeldt, a portion of the large root of *Populus monilifera*, from Delaware County, Pa., where it is grown as a shade-tree. It was very evident that the false cotton-root bark, described at the previous meeting is not derived from this species.

Three samples of fluid extract of cotton-root bark were shown by Mr. Blair. Two had the characteristic red colour of this fluid extract, while the third was more of a greenish-brown colour, caused by heat being used in a part of the process, which seemed to entirely destroy the red colour.

Professor Maisch said he had prepared tinctures of both the true and false bark, that of the latter being destitute of the peculiar red colour.

Dr. A. W. Miller presented specimens of glucose, of American manufacture. Commercially, the term glucose is applied to the liquid form, and grape sugar to the solid. The samples shown were considered of good quality, and to compare favourably with the imported article. They were made from corn starch, by the well-known process with sulphuric acid. Glucose is largely used by brewers in the United States as a substitute for malt. A very handsome specimen of white grape sugar, of American manufacture, was shown, and stated to have been made from wheat starch.

Mr. J. L. Lemberger, of Lebanon, Pa., presented yellow beeswax, of unexceptional quality, purified, by himself, by filtration through paper. He said that with proper arrangements, fifty pounds of wax may readily be filtered in a day.

The Chairman asked for information as to the difference between light and heavy oil of cinnamon, which are quoted at different prices.

Professor Maisch suggested the probability of the light oil and the impure oil being derived from cinnamon leaves, which are said to have an odour somewhat reminding of cloves.

Anilin Inks.

Dr. Bridges exhibited a large collection of anilin colours, and Dr. Miller a specimen of anilin black, soluble in water, and writing ink made from it by dissolving 1½ ounce of the former and 1½ fluidounce of mucilage of gum arabic in one gallon of water.

The practical uses to which anilin colours had been put for colouring candies, syrups, liquors, hair-oils and the like were commented upon by several speakers, and attention was drawn to the following formulæ for inks by C. H. Viedt.

C. H. Viedt objects to the use of fuchsin and other anilin colours, which are insoluble in water, and recommends the employment of those colours only as are soluble in water. Such inks do not require the addition of gum arabic or dextrin, except for slow and heavy writers, and should be so far diluted that the writing, when dry, is free from the metallic lustre of the anilin colours. The author recommends the following proportions:—

For *red ink*, dissolve 1 part of diamond-fuchsin in 150 to 200 parts of boiling water.

For *blue ink*, take 1 part of bleu de nuit (anilin blue, soluble in water) to 200 or 250 parts of boiling water.

For *violet ink*, 1 part of the colour is dissolved in about 300 parts of water. This ink is very easily affected by ordinary black copying ink, a pen containing some of the latter rendering the former at once very pale and granular.

Green anilin ink is the handsomest, but also the dearest, of all anilin inks. It is prepared by dissolving 1 part of so-called iodine green, which is soluble in water only, in 100 or 110 parts of boiling water. The writing is of a blue-green colour; if a more yellowish-green shade is desired, a little picric acid should be added.

Yellow anilin ink cannot be recommended. A solution of 1 part of picric acid in 120 or 140 parts of water is better and cheaper.

Insoluble anilin black is used for indelible stencil inks and for calico printing.

Mr. E. M. Boring exhibited ointment of mercuric nitrate, made by the formula of Mr. Rother.* This specimen, although one month old, and exposed in an ordinary dispensing jar in the shop for that time, still retained its citrine colour. and looked as nicely as when first made. Dr. Pile said he had used this formula for some time, and excepting a little alteration in the temperature when making large quantities, had found it satisfactory.

Mr. Boring also exhibited glyconin, made of five parts of glycerin and four parts of the yolks of eggs, by weight; also samples of emulsion of cod-liver oil, made with it.† The oil emulsions were made by emulsifying four parts of oil with one of glyconin, and diluting so that the emulsions contain respectively 50 and 66⅔ per cent. of oil. The former is quite mobile, while the latter has about the consistence of a 50 per cent. emulsion made with gum arabic and sugar.

Suppositories.

A paper, by George W. Kennedy, on suppositories, was read of which the following represents the principal points:—

"I do not wish to be understood as advocating the turning out of suppositories quickly, and lacking in medicinal strength or uniformity, but simply to stand by the quickest way of making them, so as to contain exactly what the physician expects them to contain. The process by moulding may answer the purpose of manufacturers of pharmaceutical preparations, who make them in large quantities and in a hurry, regardless of the equal distribution of the medicament. They are put up neatly, look elegantly, and the manufacturers are largely rewarded for their labour, but never once think of the poor sufferer, who expects immediate relief only to be disappointed, if the suppository is not of the strength represented. Some kinds are not used often, and, when stored away on the shelves for a long time, will absorb oxygen and become rancid, fatty acids being liberated, which are irritants and render such suppositories, therefore, unfit to be applied. Another objection is raised: when made with English narcotic extracts, such as hyoscyamus, belladonna, and others, such extracts contain moisture, and the suppositories, if kept for some time, mould, and are then likewise unfit for use. This proves the necessity that every pharmacist should make all suppositories fresh as wanted. I, for one, wish suppository-moulds had never been introduced, then manufacturers of the like would never have made them, as they would not be sufficiently compensated for their time and trouble, and all retail pharmacists would be compelled to make them as wanted.

"Many apothecaries favour the addition to suppositories of some hardening material, while they differ vastly what that ingredient should be, and also what quantity to be added, some advocating the use of paraffin, spermaceti, wax or Japan wax. I beg to differ with all those who favour the addition of any substance for the purpose of giving the suppository a greater degree of stiffness; it is not necessary. I never use anything but cacao butter, and while I have prepared a large number of suppositories, I have experienced no difficulty whatever. Occasionally I have heard of complaints by pharmacists that suppositories, when made of cacao butter alone, will lose their shape, and have been returned to them in a soft condition to be remade. This might, perhaps, occur when they are placed in a very warm room or near a fire; but I have never known suppositories made of commercial cacao butter to lose their shape, or even found their surface to yield to the temperature of the room where they were kept, and I have had sufficient experience in their manufacture to know that they will keep during the hottest summer months in our climate. There are some few substances that act like camphor on fats, which are quite troublesome to make; but even for suppositories of this character I use nothing but oil of theobroma. There is no doubt but much of the cacao butter, as found in the United States market, is adulterated with fats having low fusing points, and this would account for some suppositories losing their shape and becoming soft.

"Of the many excipients that have been introduced since the time when suppositories were first recommended, none appears to answer the requirement so well as cacao butter; it is decidedly the best, and, to my knowledge, no other substance or composition has been proposed that can well be substituted for it in its singular use as a medicine and vehicle.

"In using medicines by suppository, their action must be quick, and the only way to procure this is to use an excipient that will melt rapidly and uniformly. Physicians object to the use of many of the hardening ingredients in suppositories—wax, for example—because the temperature of the body will not overcome their higher melting-point; they are thus left behind, unmelted, in the rectum, in this condition they are very apt to produce local irritation, and are therefore unfit to enter into the composition of suppositories.

"This reminds me of a little incident which occurred in our town two years ago. A physician was sent for in haste to see a very sick person, and prescribed suppositories, the composition of which I cannot recall at present, with the exception of one of the ingredients, which was carbolic acid; the prescription was dispensed by a druggist, and one applied as directed. After remaining in the rectum a short time, it was discharged, and exhibited nearly the same appearance as when introduced; a second one was applied with the same result. The medical attendant examined the suppositories more closely, and found they would not yield even to the warmth of the hands, and inferred from that that a large percentage of wax had been used in their preparation. He wrote another prescription, and had them compounded elsewhere; they were applied and had the desired effect. The balance of the first box was brought to my shop, and upon examination I found the fusing point to be 120° F.

"In the opinion of the writer, the best mode of dispensing suppositories with dispatch, insuring at the same time a perfect distribution of their medicinal ingredients, avoiding all foreign matter for the purpose of hardening, and giving the satisfaction to know that the cones will melt at animal heat, is the following:

"Take of cacao butter a sufficient quantity, powder in a wedgewood mortar by first striking the butter gently until it is broken up into quite small pieces, a little care being required so as not to strike too hard, otherwise the friction produced would have a tendency to soften the butter, making it a little more difficult to manipulate; then add the medicinal ingredient, and rub all together, forming a plastic mass to be rolled out into a suitable length, and cut up into as many pieces as suppositories have been directed, each piece to be formed by the fingers and a spatula into a conical shape. It is advisable to sprinkle a little lycopodium over the fingers to prevent contact of heat from the fingers, which would soften the mass during the necessary manipulation. If made in winter, when cacao butter is much harder, by the addition of one drop of glycerin to each suppository, a mass can be formed in a much shorter time."

Mr. Mattison objected to the opinion expressed by the

* See *Pharm. Journ.*, Aug. 6, 1870, p. 107.
† See *Pharm. Journ.*, Oct. 24, 1874, p. 339.

author as to manufactured goods, as entirely too general; his experience with suppositories was in favour of moulds. Mr. Boring had used the process described, and found a piece of linen advantageous in avoiding contact with the hands. Professor Remington had made suppositories by hand, and failed to see matters in the same light as the writer of the paper, the suppositories being brittle. Mr. Shinn urged that small lumps of cacao butter could be avoided only with difficulty. To prevent this, Mr. Lemberger called attention to grating the oil of theobroma previous to admixture with the other ingredients. Mr. McIntyre believed that the process possessed sufficient merits to warrant attention to it. It was safe to say that in cases where the activity will admit of nothing but positive equal distribution, or the call is very urgent, it is possible to prepare, in from five to ten minutes, a few suppositories in condition for immediate use, which, for shape and utility will be in keeping with all requirements. By proper attention to all the details of this process, and by inserting the cones prepared with the fingers and a spatula, while yet plastic, into a hinged mould, which has previously been well cleaned and dusted with powdered arrowroot or lycopodium, and pressing them well home, after a few moments they can be readily detached from the opened mould by pressure upon the end of each suppository.

Dr. A. W. Miller read a paper on the orthography of asa fœtida.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture III.

(Concluded from page 675.)

It will seem at first sight almost incredible that such an excess of work could be put upon the heart, but it is perfectly credible when all the facts are known. The heart of an adult man makes, as we see above, 73·57 strokes per minute. This number multiplied by sixty for the hour, and again by twenty-four hours for the entire day, would give nearly 106,000 as the number of strokes per day. There is, however, a reduction of stroke produced by assuming the recumbent position and by sleep, so that for simplicity's sake we may take off the 6,000 strokes, and speaking generally may put the average at 100,000 in the entire day. With each of these strokes the two ventricles of the heart, as they contract, lift up into their respective vessels three ounces of blood each, that is to say, six ounces with the combined stroke, or 600,000 in the twenty-four hours, The equivalent of work rendered by this simpler calculation would be 116 foot tons; and if we estimate the increase of work induced by alcohol we shall find that four ounces of spirit increase it one-eighth part; six ounces, one-sixth part; and eight ounces, a fourth part.

The stage of primary excitement of the circulation thus induced lasts for a considerable time, but at length the heart flags from its over action, and requires the stimulus of more spirit to carry it on in its work. Let us take what we may call a moderate amount of alcohol, say two ounces by volume, in form of wine or beer, or spirits. What is called strong sherry or port may contain as much as twenty-five per cent. by volume. Brandy over fifty, gin, thirty-eight; rum, forty-eight; whiskey, forty-three; vin ordinaire, eight; strong ale, fourteen; champagne, ten to eleven; it matters not which, if the quantity of alcohol be regulated by the amount present in the liquor imbibed. When we reach the two ounces, a distinct physiological effect follows, bringing on that first stage of excitement with which we are now conversant. The reception of the spirit arrested at this point, there need be no important mischief done to the organism; but, if the quantity imbibed be increased, further changes quickly occur. We have seen that all the organs of the body are built upon the vascular structures, and therefore it follows that a prolonged paralysis of the minute circulation must of necessity lead to disturbance in other organs than the heart.

By common observation the flush seen on the cheek during the first stage of alcoholic excitation is presumed to extend merely to the parts actually exposed to view. It cannot, however, be too forcibly impressed that the condition is universal in the body. If the lungs could be seen, they too would be found with their vessels injected; if the brain and spinal cord could be laid open to view, they would be discovered in the same condition; if the stomach, the liver, the spleen, the kidneys, or any other vascular organs or parts could be exposed the vascular enlargement would be equally manifest. In the lower animals I have been able to witness this extreme vascular condition in the lungs, and there are here presented to you two drawings from nature, showing, one the lungs in a natural state of an animal killed by a sudden blow, the other the lungs of an animal killed equally suddenly, but at a time when it was under the influence of alcohol. You will see, as if you were looking at the structures themselves, how different they are in respect to the blood which they contained, how intensely charged with blood is the lung in which the vessels had been paralysed by the alcoholic spirit.

I once had the unusual, though unhappy opportunity of observing the same phenomenon in the brain-structure of a man, who in a paroxysm of alcoholic excitement, decapitated himself under the wheel of a railway carriage, and whose brain was instantaneously evolved from the skull by the crash. The brain itself, entire, was before me within three minutes after the death. It exhaled the odour of spirit most distinctly, and its membranes and minute structure were vascular in the extreme. It looked as if it had been recently injected with vermilion. The white matter of the cerebrum, studded with red points, could scarcely be distinguished, when it was incised, by the natural whiteness; and the pia mater, or internal vascular membrane covering the brain, resembled a delicate web of coagulated red blood, so tensely were its fine vessels engorged.

I should add that this condition extended through both the larger and the smaller brain, the cerebrum and cerebellum, but was not so marked in the medulla or commencing portion of the spinal cord.

The action of alcohol continued beyond the first stage, the function of the spinal cord is influenced. Through this part of the nervous system we are accustomed, in health, to perform automatic acts of a mechanical kind, which proceed systematically even when we are thinking or speaking on other subjects. Thus a skilled workman will continue his mechanical work perfectly, while his mind is bent on some other subject; and thus we all perform various acts in a purely automatic way, without calling in the aid of the higher centres, except something more than ordinary occurs to demand their service, upon which we think before we perform. Under alcohol, as the spinal centres become influenced, these pure automatic acts cease to be correctly carried on. That the hand may reach any object, or the foot be correctly planted, the higher intellectual centre must be invoked to make the proceeding secure. There follows quickly upon this a deficient power of co-ordination of muscular movement. The nervous control of certain of the muscles is lost, and the nervous stimulus is more or less enfeebled. The muscles of the lower lip in the human subject usually fail first of all, then the muscles of the lower limbs, and it is worthy of remark that the extensor muscles give way earlier than the flexors. The muscles themselves by this time are also failing in power; they respond more feebly than is natural to the galvanic stimulus; they, too, are coming under the depressing influence of the paralysing agent, their structure is temporarily deranged, and their contractile power reduced.

This modification of the animal functions under alcohol marks the second degree of its action. In young sub-

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts*.

jects there is now, usually, vomiting with faintness, and gradual relief from the burden of the poison.

The alcoholic spirit carried yet a further degree, the cerebral or brain centres become influenced; they are reduced in power, and the controlling influences of will and of judgment are lost. As these centres are unbalanced and thrown into chaos, the rational part of the nature of the man gives way before the emotional, passional, or organic part. The reason is now off duty, or is fooling with duty, and all the mere animal instincts and sentiments are laid atrociously bare. The coward shows up more craven, the braggart more boastful, the cruel more merciless, the untruthful more false, the carnal more degraded. "*In vino veritas*" expresses even indeed to physiological accuracy, the true condition. The reason, the emotions, the instincts, are all in a state of carnival, and in chaotic feebleness.

Finally, the action of the alcohol still extending, the superior brain centres are overpowered; the senses are beclouded, the voluntary muscular prostration is perfected, sensibility is lost, and the body lies a mere log, dead all but two-thirds, on which alone its life hangs. The heart still remains true to its duty, and while it just lives it feeds the breathing power. And so the circulation and the respiration, in the otherwise inert mass, keeps the mass within the bare domain of life until the poison begins to pass away, and the nervous centres to revive again. It is happy for the inebriate that, as a rule, the brain fails so long before the heart, that he has neither the power nor the sense to continue his process of destruction up to the act of death of his circulation. Therefore he lives to die another day.

Thus there are four stages of alcoholic action in the primary form:—(*a*) A stage of vascular excitement and exhaustion; (*b*) a stage of excitement and exhaustion of the spinal cord, with muscular perturbation; (*c*) a stage of unbalanced reasoning power and of volition; (*d*) a stage of complete nervous collapse of function.

Such is an outline of the primary action of alcohol on those who may be said to be unaccustomed to it, or who have not yet fallen into a fixed habit of taking it. For a long time the organism will bear these perversions of its functions without apparent injury, but if the experiment be repeated too often and too long, if it be continued after the term of life when the body is fully developed, when the elasticity of the membranes and of the blood vessels is lessened, and when the tone of the muscular fibre is reduced, then organic series of structural changes, so characteristic of the persistent effects of spirit, become prominent and permanent. Then the external surface becomes darkened and congested, its vessels in parts visibly large; the skin becomes blotched, the proverbial red nose is defined, and those other striking vascular changes which disfigure many who may probably be called moderate alcoholics, are developed. These changes, belonging as they do to external parts, come under direct observation; they are accompanied with certain other changes in the internal organs, which we shall perhaps discover in a future lecture to be more destructive.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Adulteration of Food and Drugs Bill.

On Friday, Feb. 19, Mr. Sclater-Booth moved the second reading of this Bill. He said that the first Act upon the subject was passed in 1860, in consequence of frequent complaints of purchasers from retail tradesmen of the injury to which they were subjected by the prevalence of adulteration. After being in operation for twelve years, it was entirely recast. In the second Act the appointment of an analyst was made *quasi*-compulsory on the authorities who had to do with it, and the law had a sanitary object. The language of the Act was founded on the idea of adulteration, which was to be prohibited, not only because it was a fraud upon the purchaser, but also because it was an injury done to the community. But this Act was soon found to be attended in its working with serious difficulties, partly caused by the want of any definition of the word "adulteration" in the Bill. Judges differed and magistrates were unable to understand what was exactly meant by the word. Again, there were some obscurities in certain operative clauses of the Bill which brought about failure on the one side and on the other gave rise to serious heartburnings. When he came into office therefore he found that though the Act was of so recent a date the time had arrived for re-considering it. Consequently about a year ago he asked the House to appoint a Select Committee with a view to some amendments during the last session of Parliament. The Committee found their labours grew upon them, time went on, and the report was not in his hand early enough to enable legislation to be pressed on last year. Having to consider the matter during the recess, the first question was whether the new Bill should be laid down on the same lines as the old, and whether the same language should be used in its operative clauses. The experienced draughtsman to whom the preparation of the Bill was entrusted had the recommendations of the Select Committee before him, but found it impossible with satisfaction to himself or with any assistance which he (Mr. Sclater-Booth) could give, to frame such a definition of the word "adulteration" as could be relied upon as the basis of permanent legislation on the subject. The consequence was that what would be regarded as the operative clauses of the Bill had been drawn up in a different way, and an attempt had been made to lay down in the clauses the things exactly prohibited and the exceptions which might fairly release the trader from penalty. By an unfortunate error of the printer, the measure was still an Adulteration of Food Bill, but it was obvious that its title should be "The Sale of Food and Drugs Bill." The Bill was arranged in five parts, it described the offences prohibited, laid down rules for the appointment and duties of analysts, and regulated the proceedings against offenders; then there were some special provisions with regard to certain offences, and some important clauses with reference to the new duties imposed on those who were to carry out the measure. It prohibited the admixture with food and drugs of any ingredient injurious to health, or the sale of any article not of the nature demanded by the purchaser, with certain exceptions. Opinions might vary as to the value of the list of exceptions which had been made, but in Committee he would be happy to hear what might be said on the subject, and accept of amendments which might appear to be reasonable. It was provided that if articles were mixed, whether in accordance with the custom of trade or the convenience of the consumer or seller, they should be mixed in proper proportions, and it would be for the seller to show that this was done. Under the old Act, the seller of retailed articles was obliged to declare orally to his customers if there had been any admixture. That provision had been seriously complained of, and it was obvious that in any shop where a large business was done, this express notice could not be given or insisted on. It was therefore now proposed that it would be sufficient if a label stating the fact was affixed to the article. The Select Committee had recommended that the appointment of analysts should be made compulsory on the authorities. But the number of candidates for these appointments was not very considerable, and great difficulty had been experienced in getting competent analysts. Then, though you might make an authority appoint an officer you could not without stringent legislation make it put the officer in motion. He knew from the experience he had in other branches of administration how easy it was to make a colourable appointment and then to take care that the person appointed should not do that which the law contemplated. Further, he did not think it advisable that the appointments should be too numerous if a smaller number would be sufficient. It was clearly desirable that a small borough, for instance, should have inducements held out to appoint the same person as had been appointed in a large borough or town in the same county to discharge the duties rather than to have separate analysts for each separate town. A refusal on the part of a dealer to allow samples of his goods to be taken for analysis was made a punishable offence. As a matter of common justice, the dealer and his wife would be admitted to give evidence at their trial. This led him to a provision to which he had given anxious consideration—namely, that if the defendant in any prosecution produced a warrant of the purity of the article from the person of whom he had bought it, and also proved to the satisfaction of the justices that he sold it in the same state as when it came into his hands, he should be discharged. Proceedings, however, might be taken against the person who had given such a warrant in the event of the article proving to be adulterated. The fines obtained from prosecutions would in future go to the authorities who were charged with the carrying out of the Act, instead of to the police, and it was hoped that this would prove an inducement to those authorities to have the provisions of the Act strictly enforced. There was an important provision that tea should be examined by the Customs on importation. Any tea pronounced by the Customs' analyst to be unfit for human consumption would be forfeited and destroyed. Altogether, he believed that if the Act was properly enforced the adulteration of food and drugs would be reduced within very narrow limits. Already analysts had been appointed in 34 out of 54 counties, and he had no doubt that under the present Bill the number of such appointments would be largely increased. The Committee were strongly of opinion that mixtures of coffee, cocoa, mustard, etc., which were expressly labelled as mixtures, should be allowed for the sake of the public taste, and their recommendation on this point had been adopted in the Bill. If the consumer desired those articles mixed, and they were harmless, there seemed no reason for prohibiting their sale. At prosecutions it would not be necessary for the analyst to attend unless his presence was expressly desired, and samples for analysis might be sent through the post. A body of gentlemen representing the public analysts had, he was happy to say, expressed approval of the general principles of the Bill, though of course they had suggestions to make in their own interest, some of which he should be able to accept. He hoped the local authorities would take steps to secure prompt execution of the Bill in case it passed into law, and at the same time to insure fair hearings for all persons concerned in cases of prosecution. He believed the provisions contained in the measure would tend to the great advantage of the public, and would at the same time do no real harm to the trading classes. All the clauses of the Bill had been carefully drawn and considered with a sole desire to provide an effective security for the purchasing public, and at the same time to remove what was a reproach to the existing law—namely, that it was gratuitously injurious to the trading classes.

Mr. Sandford thought this Bill was framed rather in the interest of the wholesale dealer than in the interest of the public. In its present form, at all events, it would lead to a very considerable adulteration of goods. He looked with considerable alarm on any measure that would lead to a restoration of the old state of things. Although the great grievance at the present moment was that adulteration was not properly defined, this Bill did not attempt to define adulteration. It left unredressed that which was admitted to be the great grievance of the present state of things. According to the 5th and 6th clauses, in order to procure the conviction of a person who sold adulterated goods it must be proved that he had full knowledge that they were adulterated. Now it was notorious that when proof of such knowledge was required it was impossible to get a conviction. As the Bill at present stood, Clause 7, was the single clause under which a conviction could be obtained, and it would have to be considered in connection with some previous exceptions, so that it would be most perplexing for any magistrate to decide upon. In amending the Act the first thing to do was to provide that a better description of analysts should be appointed. He believed that if England were divided into three or four portions, and one able analyst were appointed for each of those divisions, that number of analysts would be quite sufficient. As a member of the Committee, he examined almost every witness upon that point, and they told him, he believed unanimously, that almost every article could be sent to an analyst, no matter how distant, from one end of England to another. He was not going to mention names, but he would say that in certain towns analysts were appointed with the express understanding that they should take no action against any person in the town. Municipal councils, especially in large towns, were to a great extent composed of the very class of persons to be proceeded against. Therefore he thought the appointment of analysts ought not to be left in their hands. There was no doubt that the Act had pressed hardly upon some retail dealers, and he thought it was of very great importance that retail dealers should be enabled in some more expeditious way to proceed against wholesale dealers for having sold to them adulterated goods. If the House wished to put down adulteration, if they wished at the same time not to press heavily upon retail dealers, the persons whom they ought to endeavour to punish were the wholesale dealers. But, if one class of persons was favoured more than another by this Bill, it was the wholesale dealers. He was opposed to an inspection of tea in bond. He did not like to throw that duty on the Government. He thought it was the duty of the wholesale dealer to take care that he did not import an adulterated article. Wholesale dealers were not such poor people that they could not pay the expense of an inspection of goods which they imported into this country in order to ascertain whether they were adulterated or not. He thought that on them lay the responsibility of not introducing into this country an adulterated article. If the system of inspection of tea was to be introduced the principle should be extended to every article of food.

Mr. Muntz observed as to the word "knowingly," if it were retained in the Bill, all attempts to check adulteration would be hopeless. There was in the Bill another clause which provided that if a defendant proved he had sold the article in the same state in which he had purchased it, and with a warranty in writing to that effect, he should be discharged. It was obvious, however, that, even if there were a warranty, it would afford no evidence that the article had not been wilfully adulterated, because the warranty might have been given by a man of straw. The recommendations of the Committee were that if a warranty in writing were produced by a defendant the case should be adjourned, and that the justices should direct a summons to be issued against the person or persons from whom the defendant has purchased the articles, who, if found guilty of adulteration, should be liable to the penalties imposed. Certainly the wholesale dealer ought to be held responsible if it were clearly proved that the retailer purchased the articles of him in an adulterated state. If this alteration were made in the Bill it would be a most valuable one In Birmingham and the neighbourhood there was a large number of respectable grocers who wanted a Bill against adulteration to be passed, though they were averse from being annoyed by petty analysts who did not understand their work. If tea were to be inspected in bond, why should not wine be inspected also? More persons were poisoned by wine than by tea, and what the Committee heard about Hamburg sherry was enough to make people turn teetotallers next morning.

Mr. Pell said under the Bill no fewer than 292 separate authorities would have the power, if they chose to exercise it, of appointing a petty officer to undertake very important duties. This number of authorities was far too large. If, however, the local authority in a small place were prevented from appointing an analyst, it would have to rely on the services of the analyst appointed for the surrounding district, who, while being paid by one authority, would thus have to work for another without remuneration. Under the 10th clause 10*s.* 6*d.* was the outside sum to be paid by a person who required an analysis, and this charge, he maintained, was far too low. The amount was to be made up by the salary of the analyst, and where was the salary to come from? It was to come from one portion only of the community—those unhappy people who up to the present moment had borne many charges which ought to have fallen on the community generally. He should propose an amendment to remove this *maximum* amount to be paid for an analysis. He suggested that at all events a portion of the analyst's salary should be met from the Imperial Exchequer. There was a danger, also, that without some considerable amount of central control no analyst would be appointed at all. It ought not to be left to the option of 280 local authorities to make this appointment or not, and some provision should also be made for filling it up to the satisfaction of the central authority. If the Government exercised any supervision they should be prepared to contribute annually towards the cost of these officials.

Sir H. Peek said he had been in the tea trade all his life, and he believed that not one ounce in a ton of all the tea which came into England was adulterated here. A number of foreign substances were, unfortunately, put into tea elsewhere, but that the importers could not help. The examination of tea by sample might be very easily effected. Five samples taken from 1,000 lb. weight would be quite sufficient, and if one of those samples was found to contain matters injurious to the human organs it would not be difficult to ensure its destruction. Some of the analysts went as far as to say that all green tea was adulterated with deleterious matter, and a gentleman who was High Sheriff of Anglesey had been fined a large sum for importing the very finest green tea procurable. The fact was, that analysts wished to make themselves out exceedingly clever, and made the most of the very least quantities of foreign matters they discovered in the various samples submitted to them. With regard to the custom of the trade it was very difficult to say what should or what should not be allowed. It was a monstrous thing that the Government should be permitted to prepare their cocoa and mustard in a manner that would subject a private dealer to punishment for selling an adulterated article. When the proper time arrived he should be able, on the part of the trade, to show how the Bill might be considerably improved.

Mr. Garnier expressed his opinion that this Bill would remedy all the grievances of traders while it gave increased protection to the public. Cocoa and mustard must always be sold as mixtures, the first being mixed with farina and the latter with wheat flour coloured with turmeric. He thought it a pity that the retail trader should not be allowed to show that the article complained of was in the same state in which he had received it from the wholesale trader and so throw the liability on the latter, because although the retail dealer had at present the common law right of proceeding against the wholesale trader, the cost of taking proceedings was so great as practically to debar him from the exercise of that right.

Mr. Read remarked that under the 4th clause the offence of selling articles adulterated with poisonous matter was very severely dealt with, the penalty being £50 for the first offence, and six months' imprisonment for any subsequent offences, and there were no exceptions whatever to the operation of the clause. The reason why tea was the only article that had been, so to say, taken under the protection of the Government on being imported, was that it was the only article which had been represented as coming into this country in an adulterated state. The hon. member for Birmingham said that there was some sort of doctoring of tea in England. That might be, but the extent of such adulteration was really very trifling. It was very different with wine, which after its import was mixed and adulterated by the trade.

Dr. Playfair said it was to the operation of the existing Adulteration Acts that the people owed pure milk, pure bread, and tea of much better quality than had formerly been sold. In regard to these great staple articles of food their operation had been very beneficial, and the question was whether this Bill, while removing some of the grievances of which traders complained, would give the public the same protection as they now enjoyed. His own impression was that the Bill would not, unless they made serious alterations in it in Committee. His hon. friend (Mr. C. S. Read) said they had not given definitions, but they had given a definition of food which a lawyer would easily pull to pieces. Food was defined "every article eaten or drunk by man other than drugs." Neither tea nor coffee was eaten or drunk. It was an infusion of these articles, but this error could of course easily be remedied. This Bill said that ignorance instead of knowledge was to be required of the retailer. He was not to know his business at all, for the words of the clause were "if he knowingly"—that meant, if he dealt in milk, that he need not know his business sufficiently to know that he was selling skim milk. He of course would say he did not know the cream was away. Thus the word "knowingly" would destroy all the use of the Bill. Then there was another great exception which he must take to the Bill, and that was that the seller was to be governed by the usage of trade. Before the Act of 1872 it was the usage of trade to mix 25 per cent. of water with milk; that was the usage of the trade, and therefore anyone who did no more than that could not be punished. Then as to drugs—at one time the druggist would send his bark or other drugs to be ground, and he would get back exactly the same weight, and nothing would be charged for grinding. Why? Because the grinder abstracted a certain portion of the genuine article and adulterated what was left to make up the weight. That was formerly the usage of the trade, and that was yet done to several drugs, though not to the same extent. It was formerly the usage of the trade to mix oil of vitriol with vinegar. It made it stronger, and if there was not too much it was not injurious to health, but it was adulteration. It was the usage to mix alum with inferior flour, flour which no longer possessed any nutritive qualities at all. These "usages" would reappear, he feared, under this Bill, and if "usage of the trade" was to be allowed they might drive a coach through any part of it. The hon. member for South Leicestershire (Mr. Pell) hit a great blot in the Bill with regard to the analyst's fee. He could speak dogmatically on the point, for he was a professor of chemistry, and he affirmed that it was perfectly impossible to get an efficient analysis for 10*s.* 6*d.* If the clause remained, it simply meant that the analyst was to get 10*s.* 6*d.* from the consumer *plus* the salary he received. Scotland and Ireland were excluded from the measure, but that, he understood, would be rectified.

Mr. Salt wished to know how the Act would benefit the consumer, and how he would make use of it. It should be chiefly valuable for the poor persons, who were most affected by adulterated food and drugs, and who were absolutely at the mercy of the retail trader. The poor man might take the article he had bought to the analyst, and have it analysed on payment of 10*s.* 6*d.* But he would have no knowledge of the analyst, and was he likely to be in a position to pay 10*s.* 6*d.* for an analysis of his small purchase of flour, coffee, tea, or sugar? By the 14th clause it was provided that if a person went to a trader with the intention of having the substance that he purchased analysed, he must give notice of his intention and divide his purchase into thirds, one of which he was to leave with the dealer and another to retain for himself. Was not such a proceeding beyond the capacity of the poor man, especially as no means were provided for bringing him into direct contact with any of the officers?

Mr. Colman said that the recommendations of the Select Committee had the full support of the trade, and whatever responsibility formerly attached to the manufacturers still remained with their full consent. Objection had been taken to the expression "the usage of trade." There were certain articles—mustard being one—in regard to which there was not much difficulty in knowing what was the usage of trade. The Blue-book referred to the usages in the manufacture of mustard, and it was rather hard that the traders should be fined for selling the articles which the Government itself made for the public service. He had no doubt that, with certain amendments, the Bill might be made fair to the consumer and the retail dealer, and not unjust to the manufacturer.

Mr. Mundella inferred, from the evidence taken by the Committee, that there was very little adulteration on the part of retailers in this country, and that this was due, not so much to the Adulteration Acts as to the improvement of our fiscal system and the abolition of excessive duties the existence of which made it profitable to adulterate. Some sensational letters which had appeared in the papers were traceable to adulterators who wished to advertise their own speciality. This Bill, with a few amendments, would remove those vexations which were rendering the law nugatory. The appointment of analysts ought to be made compulsory, for the temptations to adulterate were perhaps greatest in the small places where it was difficult to make the appointments.

Mr. Ramsay said there ought to be some means of determining the chemical knowledge and acquirements of analysts, who at present differed in their opinions as to the tests to be employed in detecting the presence of certain substances in different ingredients.

Mr. Sclater-Booth explained, with reference to the objection that the poor man who could not pay 10*s* 6*d*. to an analyst had not been considered, that the police and public officer would be in duty bound to take care of such cases. He admitted that the term "knowingly" was used too frequently in the 9th clause, and he would consider whether it should not, in some instances at least, be struck out. With reference to the complaint of the hon. member for Leicester, that in addition to the charge of 10*s*. 6*d*. for analysis a supplementary charge was raised out of the rates, he could not help thinking if any charge on the rates was reasonable this was a charge of that kind. He thanked hon. members for the various suggestions which had been made, and he could assure the House they would all be considered by him with every anxiety to make the Bill as perfect as possible.

The Bill was then read a second time and ordered to be committed on Thursday, March 4.

Prosecutions under the Adulteration Act.

Adulterated Sarsaparilla.

The Town Clerk appeared on Friday the 19th inst. at the Bradford Borough Court, to prosecute several tradesmen for selling adulterated articles of food and drink. Henry Brown, a man occupying a stall in Godwin Street, was charged with having sold sarsaparilla which was adulterated.

Mr. Rimmington, the public analyst, said that there was not much sarsaparilla in the compound, but it was mixed with liquorice.

Brown was fined £1 and 8*s*. costs.

Adulterated Ginger.

Wm. Standing, shop-keeper, Manchester Road, was charged with having sold two ounces of ginger which was adulterated.

The defendant said that when he was told that the ginger was going to be analysed he told the inspector that he would not guarantee that it was pure ginger.

The Town Clerk: But that was too late; you should have done so before.

Mr. Rimmington said that the ginger was adulterated to the extent of one-third with plaster of Paris—a material which would not dissolve.

The defendant said that he sold it as he bought it himself. He was fined 10*s*., and 8*s*. costs.

Catherine Wainwright, 58, Leeds Road, was charged on two summonses with selling ginger and arrowroot which were adulterated. The "ginger" contained scarcely any ginger, but was composed principally of wheat flour, ground rice, white pepper and turmeric. The arrowroot was not injurious to health, but was adulterated with tapioca flour.

Mrs. Wainwright made the defence that she had bought the articles of some other person.

The magistrates instructed all those who made that defence to get a guarantee with the articles, and then they would have a cause of action against those from whom they bought their goods, and could compel them to pay their fines. Mrs. Wainwright was fined 10*s*. and costs in each case.

Milk Prosecutions in Dundee.

Several prosecutions for the sale of adulterated milk have recently taken place in Dundee Police Court. In one, Alexander Scott, a farmer, was charged with having supplied to a dealer milk which had been adulterated.

In the course of his evidence, Mr. Macdougald, the public analyst, stated that the milk in question contained only 10·65 per cent. of total solids. His standard for normal milk was 3 per cent. of fat, and 12 per cent. of total solids. He had fixed upon that standard after a number of experiments tried on cows in Edinburgh. He arrived at it by striking an average, and then making a reduction so as to be certain of ensuring milk dealers full justice. There might have been one or two below the average. The solids not fat varied very little. The cows experimented on were fed on hay, potatoes, draff, and turnips. He thought 12 per cent, a very reasonable standard. Professor Wanklyn took 12·5 per cent. Referred to a standard reported to have been fixed by the Society of Public Analysts that milk should contain "not less than" 9 per cent. by weight of solids not fat, and 2·5 per cent. of butter fat, Mr. Macdougald said that was the minimum, and a very poor one. His reading of the article was that 9 per cent. of solids not fat and 2·5 per cent. of fat was the lowest milk that should be allowed to pass.

For the defence, Mr. Frank W. Young, analytical chemist, deposed that in his opinion 12 per cent. was too high a standard. Milk possessing 11·5 of solids would certainly pass as good average milk. There had been samples of pure milk with much less total solids. Were he to get such a sample of milk he would assume it to be pure milk, and all public analysts in the country would do the same. He had met with pure milk containing as low as 11 per cent. total solids. He considered it probable that a sample with 9·10 of solids, might have come pure and unadulterated from the cow. Such cows were exceptional, and probably it was soon after calving. A good deal depended upon feeding, and also upon the way the cows are kept, in producing quality. Milk with 10·65 of solids would probably be unadulterated.

The Baillie decided that the milk had been adulterated, and inflicted a penalty of 50*s*.

Supposed Poisoning by Aquafortis.

On Monday the 15th instant, an inquest was held at Wycombe Marsh, Bucks, to investigate the circumstances attending the death of Silas Gill. It appeared that in consequence of the deceased having been taken ill and stating that he had swallowed about half-a-quartern of aquafortis, a medical man was sent for who found him suffering very severely. Some salad oil was procured, of which deceased was induced to swallow about two ounces. The surface of the body was then quite cold, but he was quite sensible. He said he was tired of his life, and had been out of work.

It was proved that deceased had previously attempted to commit suicide, and the jury returned a verdict that he died from the effects of poison taken while in a fit of temporary insanity.

Review.

COMMENTARY ON THE BRITISH PHARMACOPŒIA. By WALTER G. SMITH, M.D., Dublin, etc., etc. London: Smith, Elder and Co. 1875.

With the new year, appeared a volume from the pen of a Dublin physician, whose frequent contributions to this Journal must have made his name familiar to pharmacists.

The author's main object was (to quote from the preface) "to supply practitioners and students with an explanatory commentary on the drugs and preparations of the British Pharmacopœia."

In the introduction he alludes to a feature for which he claims special advantage—viz.: "having kept the book within reasonable limits, and avoided the needless repetition of the characters given in the Pharmacopœia."

He seems to have recognized the difficulty in condensing pharmacy, materia medica, botany, chemistry, and medicine, as well as remarks upon *fashionable* remedies, not yet sufficiently established to find a place in the national pharmacopœia, into a volume of *seven hundred pages*, with the use of a type similar to that of Attfield's 'Chemistry'—of which latter work the commentary, *externally*, is almost a *fac simile*.

The author having expressed his determination for brevity upon unimportant matters, we cannot refrain from remarking that we are surprised that he did not discard the mention altogether of such nostrums as "liq. carbonis detergens," "nepenthe," Holloway's pills and ointment, Dalby's carminative, etc.; for the bare recognition accords to them undesirable prominence, and certainly does not aid the cause of true pharmacy.

The general arrangement of the work is alphabetical, and the order of the British Pharmacopœia is maintained throughout; the commentary upon each drug being subdivided into "origin, characters, and tests," and "uses in pharmacy and medicine."

All necessary details of such indigenous plants as are the source of officinal drugs are given at length, while those from foreign sources are described as briefly as possible, leaving space, as the author remarks, for "the introduction of more useful matter."

The botanical origin is not always followed by the geographical source; which might, with advantage, have been included in every case without fear of increasing the size of the volume to an extent that would have been necessary had the history, production, and commerce been commented upon.

We are not at all prepared to cede that the description of certain officinal drugs by the author is in all cases equal to the clear and concise language of the Pharmacopœia. For instance, Almonds are thus described:—"Bitter almonds are distinguished from sweet almonds by being shorter and thicker—they should be entire, white, and brittle; when injured by keeping, or of bad quality, they are soft, flexible, and translucent."

This is not a clear description of the bitter and sweet almond to our mind; neither is it sufficiently explicit to put into the hands of a student, for no allusion to the actual shape or length of either variety is made; neither is the presence or absence of odour under certain circumstances made a distinguishing feature. Indeed, as it stands, the description of the almond as "entire" is superfluous, and certainly inaccurate when giving the colour as "white," unless it be followed by the word *internally*; for almonds have a cinnamon-brown seed coat.

It may be argued that a student ignorant of materia medica would know an almond, and also distinguish the bitter from the sweet variety; the former, doubtless, most would be capable of doing, the latter, however, is at times exceedingly difficult. Upon the almond and its products the author is "at sea," for "oleum amygdalæ" is said to be made by pressing the bitter or sweet almond in bags between plates *slightly warmed.*

Now if there is one practice more than any other that is discountenanced in this country, it is the use of heat in the expression of almond oil.

The yield of fixed oil is stated from bitter almonds as 28 per cent., and from sweet almonds 54 per cent.; by what means, whether hydraulic pressure or by ether, is not stated. If pressure be intended we imagine 43 to 44 per cent. from both varieties of almond would have more accurately represented the yield, and if by ether as a menstruum, then upwards of 50 per cent. might have been stated—certainly not 28 per cent., by either process, or from either variety.

But a few pages beyond the note upon almonds it is stated "nutmeg is the only officinal drug from which is derived both a fixed and a volatile oil."

Had this statement been made with the substitution of the words "*in which exists*," for "from which is derived," we would not have dissented; but as it reads we must say that we remember another officinal drug from which is derived both a fixed and volatile oil, viz., bitter almond.

It would have been possible in a short description of some of the interesting drugs to have added something in addition to a condensed paraphrase of the pharmacopœial description. Essence of lemon, for instance, is said to be one of the few essential oils made "by simple expression" as well as distillation. This does not convey much information to a student, for the ordinary press is not used, but a process of actual squeezing by the hand is resorted to, the essence being absorbed by a sponge. In short that portion of the work devoted to fixed and volatile oils has not had the care bestowed upon it evident elsewhere, for in addition to the errors to which we have alluded there are discrepancies in the specific gravities, percentage yield, and other minor points which render the work inadmissible as one of reference upon this subject.

The commerce of drugs cannot be properly handled by strangers to the port of London who necessarily know nothing of the special trading attached thereto; we must therefore excuse the author's statement that Chinese, *Russian*, and European rhubarbs are the principal commercial varieties. We imagined it was very generally known by this time that Russian, or the so-called "Turkey rhubarb," has for some years past been entirely absent from commerce.

The pharmacy portion of the work has been written with considerable care, and is sufficiently explicit for the use of students in medicine, who cannot wish to be experts in this art.

Here again, we notice some few errors and misapplied terms. Aromatic sulphuric acid of the Pharmacopœia is made synonymous with "Mynsicht" elixir, quite contrary to usual practice in pharmacy, and is therefore liable to mislead. Also, when the author states the amount of extract yielded by certain fresh plants, roots, etc., he is not always accurate.

Extract belladonna from the fresh herb is said to be yielded in the proportion of 5 to 10 per cent. (should have been 5 to 6 per cent.); extract opium as 66 per cent. (B.P. gives 50 per cent.); extract of nux vomica as 7·8 per cent. (should have been about 12 per cent.), and so on.

Reference is also made to "the coagulation" of the colouring matter in making green extracts. Is it coagulated or separated?

Upon that portion of the work devoted to chemistry, the best results have been achieved, and good use has been made of the space afforded for the subject.

The introduction, under each of the principal metals, of "a pedigree or genealogical table" of its preparations is a very excellent feature, as a student is thereby enabled at a glance to see the derivation of a series of preparations.

Those desirous of gaining information upon the manipulation necessary for the manufacture of the officinal acids, oxides, salts, etc., will, in this work, find very excellent general ideas upon the subject, quite sufficient, we should say, for a student of medicine, although insufficient for one desirous of becoming *thoroughly* conversant with pharmaceutical chemistry.

Many minor points in connection with this subject are hardly in accordance with our views and observations. Certain figures also will bear correction; of these some are typographical errors, as when the atomic weight of iodine is put at 1·27.

As the recent British Pharmacopœia addendum has been included in the commentary, we should have preferred to have seen some of the preparations there enumerated more enlarged upon, whereas many have been dismissed in a few lines.

Adulteration is so frequently alluded to, that we cannot pass the remarks made under this head without notice. The importance of calling the special attention of medical practitioners, pharmacists, and others, to means by which they may detect impurities and check fraudulent sophistications, cannot be overrated; but at the same time we must protest against those spurious lists of substances said to be liable to adulteration, which it is customary for authors now-a-days to parade, upon the authority of writers of the first half of this century.

We will give a few quotations from the list before us:—

Citric acid. "Most common impurity, tartaric acid and lime."

Belladonna leaves. "Attention to the character of the leaves, ovate, acute, entire, smooth, will distinguish them from any of the adulterations that have been practised, such as *Digitalis purpurea* (foxglove), *Solanum nigrum* (woody nightshade), *S. Dulcamara* (bittersweet), *Verbascum Thapsus* (mullein), *Hyoscyamus niger* (henbane)."

Powdered capsicum "is adulterated with red oxide of lead, and with coloured sawdust."

Aniseed oil, "in consequence of its high price, is sometimes adulterated with spermaceti, wax, camphor, or alcohol."

Cajeput oil, "from its high price (?), is occasionally adulterated with oil of turpentine or other oils."

Castor oil "is adulterated with other fixed oils (olive oil, etc.), and a most dangerous fraud consists in the addition of a small quantity of croton oil to it with a view of increasing its activity."

Anyone who has taken the trouble to examine the substances enumerated as now met with in trade in Great Britain, must know, that in the main the above statements are without foundation.

The recent 'Pharmacographia' by Hanbury and Flückiger is a master-piece upon this as upon other matters, and we cannot remember that reference is made in that work to the fraudulent adulterations of the drugs we have mentioned and in the way indicated. We would strongly recommend authors when commenting upon adulterations to make such statements as are based on their own observations only, and also in addition to be so charitable as to believe that there are to be found honest traders in physic as in other wares.

Surely it is the duty of an author when making assertions, which he personally cannot verify, to append by footnote or otherwise his authority for the statement.

Having then hastily glanced at the work before us from a pharmacist's point of view, in closing our remarks we would not, in justice to the author, lose sight of the special object for which he designed the book, viz., "to supply practitioners and students with an explanatory commentary on the drugs and preparations of the British Pharmacopœia."

To these gentlemen for whom the work was designed we commend it for perusal, and in the hands of medical practitioners leave that portion specially devoted to "the uses in medicine" of the many substances of the officinal materia medica, a subject upon which we do not feel competent, neither is it within our province to offer authoritative opinions.

Correspondence.

The London and Edinburgh Board of Examiners.

Sir,—I am afraid the members of the Scottish Examining Board will not feel flattered by the remarks made at the last meeting of the Council, and by some of the correspondence in the Journal. Frequently of late I have heard various members and associates of our Society decrying other members and associates who have "only passed in Edinburgh." Invariably, however, I have found these men of the class who are for ever parading themselves before the public as members, etc., "By Examination," and who never forget to add M.P.S., M.P.S.G.B., or some other string of letters, to their signatures. Nothing, in my opinion, tends to degrade our calling so much as this. The public are becoming aware that a man may be an M.P.S. and yet not be an educated man, and they instinctively condemn the whole for the shortcomings of the few. When people place a lot of initials after their names, and are always reminding one of their never-to-be-forgotten examination, is it to be wondered at that they should be expected to possess considerably more knowledge than they are ever found to do?

My reason, however, for writing to you, Mr. Editor, is to explain why at least some of our young men go to Edinburgh rather than to London. To begin with myself, I passed my Minor in London, and my Major in Edinburgh, and for these reasons:—First, I had a decided objection to the manner in which I had been spoken to and watched by at least one of the examiners of the London board, and being of a somewhat nervous temperament I felt a peculiar dread of going there again. I must add, however, that the majority of the examiners were extremely courteous and kind. Second, I had several times been in London, and had never been in Scotland, and therefore I decided on Edinburgh.

Of course, whilst there, I was brought in contact with others who had come for a like purpose, and from the conversation I had with them I learnt the reasons why several had given the preference to Edinburgh.

More than one was of opinion that the number of candidates for examination in London was so numerous that it was utterly impossible for them all to be fairly tried. The examiners could not devote sufficient time to each subject; this haste and the excitement together completely unnerves many of the candidates, more especially those who have not had the advantage of a course at some of the London establishments, and who have little or no real idea as to what the examination is like. Consequently the poor lad who has studied hard in some sequestered little town, with only the aid of his books, is plucked, whilst the numbskulls who can afford to have a carefully selected stock of knowledge driven into them, carry all before them. The former, unconscious of the value of his knowledge, is nervous, and fails; the latter, blissful in his ignorance, fears nothing, and wins.

Other candidates had heard so much about the so-called catch questions, and the severity of the examiners, from those who had been plucked in London, that they had decided to submit themselves to the board about which they knew that at least they would not be more severely handled than in London.

One candidate only acknowledged that he had come to Edinburgh because he had been previously plucked in London.

I cannot myself judge of the relative stringency of the examinations in London and Edinburgh, but when I went for the Minor in London, I found the examination much less stringent than I expected; whereas, the Major in Edinburgh proved much more severe than I had anticipated. By each and all of the members of that board the candidates are treated with every consideration, and I shall always remember with pleasure the hours I spent in their company, and the kind words of encouragement addressed to me by Dr. Maclagan.

Some member of the Council lately asserted that Dr. Maclagan examined the candidates as to their microscopical knowledge. This I believe to be incorrect. Dr. Maclagan certainly conversed with me on the subject, and I examined various objects with the microscope, but I never understood that that was any portion of my examination.

I, however, must conclude; but will add that I think the greatest average of candidates who pass in Edinburgh arises from two causes: the better men preferring Edinburgh, and the greater amount of care taken by that board of examiners to thoroughly test the capabilities of the candidates. I only wonder more do not avail themselves of the opportunity of visiting Scotland, and I am confident this would be the case if a lot of the "students" only thought they would be more likely to pass there than in London.

England.

February 23, 1875.

Adulteration of Food and Drugs Bill.

Sir,—This Bill has now been read a second time before the House of Commons and promises speedily to become law. It is as well, therefore, for all who are interested or concerned in its working to give the subject their careful consideration, for the purpose of pointing out defects and remedying errors.

I have watched the operations of the present Act, and have been attempting to discern in the future the results which will follow the enforcement of the new Bill. My first impression is that there will be a scarcity of suitable men to fill the appointments which will have to be made, and my second, that no body of men can be so readily fitted to occupy these posts as pharmaceutical chemists. It will be as well, therefore, for these gentlemen to devote as much attention as possible to the subject, so as to be enabled to seize the advantages that may be offered them of thus adding to their incomes.

I think the new Act more clearly defines the duties, etc., of the analyst, and it will not be quite so perplexing to magistrates, who may, therefore, be able to arrive at decisions not quite so diverse as heretofore. The parts of the Act treating of the "proceedings against offenders," "expenses of executing the Act," and the "special provision as to tea," will ultimately greatly facilitate its working, and will at once remove or prevent the infliction of such hardships as the retailer has had to suffer where the present Act has been strictly enforced.

In the future, vendors of articles of foods and drugs will certainly not be able to grumble at the definition of adulteration which is given by this Act. The person who adds salt to his cayenne may claim that it is added to improve its appearance, and consequently that it comes under the exceptions of clause 6. If lead is found in a mineral water, the manufacturer may plead that it has not knowingly been added. These exceptions under clause 6 are the weak points in the Bill, affording numberless pretexts and excuses to the fraudulent adulterator. Yet possibly it may be better that the Act should be too lenient than too severe. Clause 7, however, will afford many analysts an opportunity of certifying an adulteration, and may cause many frivolous and vexatious prosecutions. On the whole, however, I think the Act may work as satisfactorily as it is possible for any Act to do which has to deal with so subtle and complex a subject. My prognostications, however, are not worth much, for experience only can fairly prove the merits and demerits of such a Bill.

I almost think "adulteration" could have been more clearly defined by the following clauses:—

1. The addition to any article of food or to any drug of any ingredient for the purpose of increasing its weight or bulk so as thereby to yield an increased profit to the vendor and mixer.
2. The addition to any article of food or to any drug of any colouring or other matter for the purpose of imparting to an article of inferior value the appearance of one of better quality.
3. The abstraction from any article of food or from any drug of any ingredient whereby its value as a dietetic or as a medicine shall be impaired.
4. The partial or complete substitution of any substance for any article of food or for any drug.
5. The presence in any article of food or in any drug of any deleterious substance, either purposely added, or arising from imperfect purification, or from defects in the method of preparation.

No person should, however, be guilty of an offence who, selling any article of food or drug mixed with any substance not positively injurious to health, duly labels the same at time of sale with the names of the ingredients contained in the mixture. Should, however, any deleterious substance be present, the vendor should be liable to the full penalty of the law.

Buxton.

The Chemistry of the "Tar Antiseptics."

Sir,—In the *Pharmaceutical Journal* of 13th inst. a letter appears by Mr. C. Lowe which contains some strictures on a paper of mine on the chemistry of the tar antiseptics, published in your issue of the 9th ult. I should not have noticed a communication so manifestly biassed were it not that the statements made therein, whilst professing to correct error and convey true information, are in reality of a most careless and unguarded character.

Mr. Lowe states that I began by giving a much too general outline of the process of coal gas tar distillation. In other words, if Mr. Lowe had had the conduct of the paper he would have occupied the time of the evening with discursive and needless details upon matters indirectly connected with the subject in hand. My time being limited it was necessary to give most of the processes in outline only, and Mr. Lowe's insinuation that the phenol I described might contain various impurities is inconsistent with the words I used and is, I fear, suggested by something other than a desire to convey correct information. Several instances occur where the ideas objected to are not found in the words I employed. Mr. Lowe builds a structure of imaginary errors by spelling me backwards a little, and then manfully charges at them and dissipates them. Of this character is the charge that I claim the merit of having discovered pure carbolic acid because I recommended a name less misleading than the term acid. The phrase "absolute phenol" was proposed, and the granular form of this product suggested by me as likely to prove useful, and the suggestion has been amply justified. To the discovery of pure carbolic acid I made no claim, for the reason (sufficient for me) that I did not discover it. The idea is not suggested by my paper, but is the offspring of Mr. Lowe's ready invention.

Mr. Lowe, for the most part, avoids the actual subject of the paper, and points to the necessary want of detail in matters that are briefly named: he objects to my process for preparing rosolic acid, and states that the greater portion of the phenol is not present as sulphophenic acid. I can only say that if Mr. Lowe does not bring the greater portion of the phenol into that form he works in a crude and wasteful manner. My statement that rosolic acid could be obtained in a crystalline form from the aurin of commerce when freed from (not "by the removal of," as Mr. Lowe misquotes) excess of phenol is described as incorrect. Without wishing to give the "reply churlish," I will merely repeat my statement. I referred at Liverpool to Messrs. Dale and Schorlemmer's paper for the details which, as in other cases, it was impossible to enlarge upon. With reference to the nonformation of rosolic acid under the conditions described by Smith and Jourdin, I accept the more recent results of Caro.

Mr. Lowe is also querulous on the process given for producing picric acid, although it is strictly accurate; but for reasons already given, the modifications and minutiæ necessary for economic production on a manufacturing scale were not described in detail.

Mr. Lowe approaches the actual subject of the paper where he treats of my description of pure phenol—and here, at last, two statements which I have distinctly made, are distinctly impugned and correct information volunteered. I state that the boiling point of pure phenol is 184° C., whilst Mr. Lowe states it to be 182°; and further adds, that these two degrees of boiling point indicate a material impurity in the acid boiling at 184° C. In another place Mr. Lowe refers to Messrs. Dale and Schorlemmer as trustworthy authorities, and I should be equally willing to accept their statements on a scientific point. In the *Journal of the Chemical Society* for 1873, p.441, these gentlemen in speaking of their experiments on aurin, say, "We therefore prepared the colouring matter from pure phenol boiling quite constantly at 184° C., and melting at 42°, a large quantity of which was kindly placed at our disposal by Messrs. Chas. Lowe and Co." Mr. Lowe must either admit that 184° is the correct boiling point, or that his "pure" phenol contains a material amount of impurity.

I also state that pure phenol is not deliquescent, and this statement is improved by Mr. Lowe as follows:—"As regards the non-deliquescent properties of pure phenol, Mr. Bickerdike does not seem to have recognized the fact that pure phenol attracts moisture from the air like pure cresol, the hydrate in the one case being solid and in the other case liquid at ordinary temperature, etc." I certainly do not recognize the similarity which Mr. Lowe describes; the absorption of moisture in the case of phenol being extremely slow as compared with cresol and the non-deliquescence of pure phenol is one of its most conspicuous properties, distinguishing it from the qualities contaminated with cresol.

The above remarks, which include all the objections enumerated, will enable your readers to estimate the value of Mr. Lowe's critical method, which would doubtless be more effective if it were rather more guarded and less impetuous.

W. E. Bickerdike.

Eagle Chemical Works, Church, near Accrington, February 16, 1875.

Sir,—In your Journal of the 13th inst., there appears a letter signed "Chas. Lowe," purporting to be a criticism of a paper read before the Liverpool Chemist's Association, by Mr. W. E. Bickerdike, on "The Chemistry of the Tar Antiseptics." In this letter the following paragraph appears:—"Mr. Bickerdike's partner, Mr. Bowdler (a chemist for some time in the employ of the late Dr. Calvert), should have been able to give him more correct and extended information with regard to pure carbolic acid and its properties than is displayed in his paper."

I have carefully perused the paper of Mr. Bickerdike, and as your readers will note, no reference whatever is made to my name or to the name of our firm, which appears to have been studiously avoided by Mr. Bickerdike, and very properly so, as it was given at request and not for trade purposes. Mr. Chas. Lowe (like myself, a chemist formerly in the employ of the late Dr. Calvert, as he chooses to express it), is, therefore, making an unwarrantable use of my name in thus introducing it into his letter.

With the paper of Mr. Bickerdike I have had nothing whatever to do, and as he is well qualified to reply to Mr. Lowe's insinuations, I have no doubt he will do so.

Mr. Lowe having referred to my connection with the late Dr. Calvert, I may add that having had the management of the works of Messrs. F. C. Calvert and Co. in my hands, I am acquainted with the growth and development of this branch of manufacture, and it would have given me some satisfaction to have read the generous admission of Mr. Lowe, that pure carbolic acid "is well known in the trade, being manufactured by our firm (C. L. and Co.), and that of F. C. Calvert and Co.," were I not informed that Messrs. Lowe and Co. have recently acquired the name and use of the works of Messrs. F. C. Calvert and Co.

Mr. Lowe further says, that a full description of the product and process of its manufacture was published simultaneously by the late Dr. F. C. Calvert and himself in 1867; but Dr. Calvert had already. in 1865, published a paper which appears in the Chemical Society's Journal for that year, "On a Crystallized Hydrate of Phenylic Alcohol," in which, singularly enough, no reference whatever is made to Mr. Chas. Lowe, and yet this preparation of a crystallized hydrate and its subsequent purification is the subject of C. L. and Co's. specification dated April 24, 1874, and constitutes "the letters patent" to which he refers.

My attention has recently been drawn to a printed price list of Messrs. F. C. Calvert and Co., dated October 1st, 1872, to which has been added a note in red ink dated January 1st, 1875, to the effect "that pure carbolic acid can only be obtained from F. C. C. and Co., as the manufacture and sale of this product is fully protected by patent and trade mark."

As the purpose of this is so manifest and calculated to mislead, I may state for the information of your readers, that I know of no bar whatever to prevent any person from carrying on the manufacture of pure carbolic acid if they can do so with any profit and can supply a satisfactory product.

We have done this for the last seven years according to the process of the late Dr. Calvert with such modifications and improvements as experience has suggested.

Perhaps the fact that the manufacture of some considerable quantity of carbolic acid has been placed in our hands, may account for this unnecessary attack upon myself; if so I would simply commend to Mr. Lowe's attention, what is applicable to business as well as to life, namely Darwin's doctrine of "the survival of the fittest."

Arthur C. Bowdler.

Church, February 16, 1875.

F. Balkwill.—"Ess. Amygd. Amar." is generally made by mixing one part fluid of the essential oil of almonds, freed from prussic acid, with seven parts of spirit of wine, 56 O.P.

J. P. A.—There is no "Irish Pharmacy Act." The only persons at present entitled to dispense the prescriptions of qualified practitioners in Ireland are the Licentiates of the Apothecaries' Hall of Dublin. The Government has promised, if possible, to bring forward, during the present session of Parliament, a Bill, having for its object the remedy of the inconveniences resulting from this state of the law.

A. B.—Resin of guaiacum can be detected by its alcoholic solution rendering the fresh-cut surface of a potatoe *blue.* We know of no reliable test that will distinguish resin of scammony as obtained from scammony of trade by means of ether, from resin of scammony made direct from the root by alcohol.

"*Country.*"—Neither Members nor Associates have a right to make use of the arms of the Society in their individual capacity.

E. J.—The label does not appear to be liable to a stamp, but we are unable to state positively that this would be the view of the excise authorities.

C. D.—(1) Apply to the Secretary of the University, Mr. Thomas Gilbert. (2) We have no knowledge of such a book.

Giving Copies of Prescriptions.—"*Desideratum*" complains of what he considers to be a growing evil, of persons asking for copies of prescriptions that have been entered in the books of one establishment, for the purpose of taking them to another to be dispensed, and suggests that in such cases a charge should be made. The necessity for such a course is obvious, unless, indeed, it would not be better to refuse to supply such copies at all.

"*Minor.*"—Undoubtedly the dispensing of medicines by medical men, and the cutting down of prices by some chemists and druggists, are evils to be regretted; but we fail to see that those practices would justify a chemist and druggist in attempting the performance of duties for which he is unqualified.

T. Walton.—The study of books alone will not be "sufficient" to enable you to pass the examination in the subjects mentioned. With this qualification the books referred to are well adapted for the purpose; but it is not advisable to confine your reading to a single author. (2) A formula for Syr. Ferri et Calcis Lacto-Phosp. will be found in the *Pharm. Journ.* for Jan. 31, 1874, p. 610. (3) The following has been published as the formula of "Composition Powder" (Dr. Coffin's):—

℞ Pulv.	Bacc. Lauri.	℥iv.
	Zingib. Opt.	℥ij.
	Pini Canadensis	℥j.
	Caryophyllarum.	
	Pip. Cayenne, ana	℥ij.

Mix. Dose: a teaspoonful in a cup of hot water, sweetened.

H. F.—The prescription is one concerning which, if you have any doubt, it would be advisable to communicate with the prescriber.

T. Randall.—Some of the anilin dyes would probably answer your purpose. See p. 690.

"*Français.*"—With the first preparation we are unacquainted; the second is a proprietary article, the composition of which we are unable to state.

W. G. W.—The Registrar will deal with such cases as they arise.

J. Whitfield.—We are informed by the Assistant-Solicitor of Inland Revenue that the article recommended in the handbill forwarded by you is liable to the medicine stamp duty.

Communications, Letters, etc., have been received from Mr. J. Farmer, Mr. Bell, Mr. Candy, Mr. Rimmington, Mr. Learoyd, Mr. Chipperfield, Professor Flückiger, Inquirer, Common Sense, A Working Assistant, A. A., G. F., (Vienna), M. P. S.

LEAD PLASTER.*

BY CHAS. UMNEY.

At the meeting of the British Pharmaceutical Conference held in London last year, a most interesting paper upon the official plasters was read by Mr. A. W. Gerrard,† who, in commenting upon lead plaster, is reported to have said that it was "too soft and sticky;" in which statement he was corroborated, in the discussion that ensued, by several pharmacists.

At that meeting I said that I looked upon the proportions given in the British Pharmacopœia as a mistake, also that the formula of the London Pharmacopœia ordering a larger quantity of litharge would produce a better lead plaster than that made by the official formula.

Professor Redwood argued in the opposite direction, and said the alteration to the present proportions had been made with the express object of making the plaster more sticky, also, that the amended formula closely approximated that used some years ago by Dr. Scott, who was "a medical man celebrated in wound cases at that period."

Mr. Giles following Professor Redwood said:—

"I think what has been said is a very sufficient answer to the remarks made with regard to emplastrum plumbi, as a plaster standing by itself, but it leaves us in the same embarrassment, with reference to the production of this plaster as a basis for other plasters. Undoubtedly the consequence of the change has been to make the other plasters of the Pharmacopœia inconveniently sticky, and, as a matter of fact, I believe, wholesale houses have modified the form, and that we do not now get them strictly according to the B. P. I do not know that there is any harm in that, but in a future edition it might be advisable to introduce an emplastrum adhesivum, where a sticky plaster is required, and the old emplastrum plumbi, as a basis for other plasters."

Here the discussion dropped, but only to be renewed in the correspondence columns of the *Pharmaceutical Journal* of September (page 240) and October following (page 319), by writers who strongly upheld the superiority of a plaster made with a quantity of litharge equal to, or even in excess of, that of the London Pharmacopœia.

As it appeared that the views I held and expressed at the Conference meeting were also shared by others, notwithstanding the contrary opinion Professor Redwood then expressed, I determined to make further experiments, and test the accuracy of my former conclusions.

Accordingly, in the early autumn, I went through the same process I had used ten years previously when the first British Pharmacopœia (1864) was introduced (in which the formula was first altered), and manufactured both on the small and large scale.

The plaster produced on the small scale (7lbs.) was made strictly in accordance with every direction, as was that on a large scale (150lbs.), save the time it was boiled—six hours, at least, being devoted to the making and final heating of the plaster, with a pressure of steam ranging from one to one and a half atmospheres.

The product in appearance was not dissimilar to lead plaster properly made by other formulæ, but the manipulation was difficult, and it was soon discovered, by those accustomed to shape the plaster, that some alteration had been made in the proportions of ingredients.

Even at that season (September) it was impossible for the plaster to be used for some days. Eventually it was disposed of, with a result corresponding to that so well remembered ten years previously, viz.. *complaints and disappointments*, anything but satisfactory from a commercial point of view.

Fearing there might be a prejudice on my part against the official formula, I determined to submit specimen rolls of both British Pharmacopœia and London Pharmacopœia plasters to a few pharmacists, without any remark or identification than distinguishing letters, asking their opinions upon them as adhesive plasters, and also their suitability as a basis for other plasters.

The replies I received in favour of the London Pharmacopœia plaster were six, one only giving preference to that of the British Pharmacopœia, appending to his remarks "that he had only had an opportunity of experimenting upon it as adhesive plaster, and not as a basis for other plasters."

I will not trouble you by reading these communications, for I see some of the gentlemen who kindly favoured me with their opinions are here this evening: with your permission, however, I will read you *three* extracts from their letters.

(*a*) "The samples are not difficult to distinguish, no doubt the one marked 'A' is the B. P. judging from its softness and the greasy stain it imparts to the wrapper, which is due to uncombined oil.

"The spread plaster of this has more the character of a resin ointment than lead plaster, so that when applied to a limb it does not impart firmness, but soon gets out of place; on the other hand the plaster marked 'E,' (P. L.) is firmly adhesive, retaining its position and supporting the parts to which it is applied."

(*b*) "The B. P. plaster, when spread, took longer in hardening or drying, and is now, after six days, unfit for folding or rolling up, except in cold weather. For the commercial plaster manufacturers P. L. would be preferable to B. P."

(*c*) "The B. P. is undoubtedly more "sticky" when cold and fresh than the P. L., but the latter has the advantage of being firm when cold, and equally sticky when warmed.

"After application the B. P. gets so soft from warmth that it slips, and will not keep the edges of wounds together."

"These experiences are partly those of medical men."

"A much more satisfactory plaster can be made when using alcoholic extracts of aconite and belladonna, with the P. L. emp. plumbi, as a basis."

So much then for the opinion of these gentlemen upon the plaster I forwarded to them for experiment. Just one opinion more, from one who has been occupied at least a quarter of a century in the manufacture of pharmaceutical preparations on a large scale.

He writes—"Tried to supply the B. P. article at first, but finding it was not satisfactory, we adhered to our old form and shall continue to do so, unless some evident improvement be suggested. Practical men know that it would be absurd to attempt the supply of the B. P. plaster during the heat of summer."

Enough has been said to show that the lead plaster of the British Pharmacopœia is not generally approved, and that in trade it is still the custom

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, on Wednesday, March 3, 1875.

† *Pharm. Journ.*, Aug. 29th, 1874.

to use a formula approximating, if not coinciding with that of the last London Pharmacopœia.

Lead plaster, as you know, is neither a novelty nor is its use confined to Great Britain, for it has stood the test of at least two centuries, and is now used throughout the civilized world.

I would ask you to glance at a table I have prepared showing the proportions of litharge to *one hundred parts* by weight of olive oil, or of lard and oil, or lard only, as formerly used in Great Britain and Ireland, when we had three Pharmacopœias, and as now used on the continents of Europe and America.

Pharmacopœia.	Olive Oil.	Lard.	Litharge.
London, 1746	100	...	56·0
„ 1824	100	...	56·0
„ 1851	100	...	53·8
Dublin, 1850	100	...	54·5
Edinburgh	100	...	49·9
United States......	100	...	53·5
France..............	50	50	50·0
Germany............	50	50	50·0
Austria	...	100	50·0
Greece	100	...	55·5
British, 1864 & 1867	100	...	43·6

It would seem from this table that the amount of litharge did, and now does, vary from 50 to 56 parts to 100 by weight of oil, or a mixture of lard and oil, as in France and Germany, or lard only, as in Austria, and as far as I have been able to ascertain, no official formula in any Pharmacopœia has given a proportion of litharge so small as that of the British Pharmacopœias.

The custom of the trade in this as in most matters, must be of considerable importance in deciding the question at issue.

From inquiry I have made, not only in London but in other cities, I find that emp. plumbi is seldom made on a large scale by the official formula for druggists' use, but that from 50 parts to 60 parts of litharge to 100 parts by weight of oil is more generally adopted, and that in no case (as far as I have been able to ascertain) do the manufacturers of the adhesive plaster of surgery and trade, which is spread in hundreds of thousands of yards annually, use the lead plaster of the British Pharmacopœia.

The composition of the British Pharmacopœia plaster may be described as a lead soap, with undecomposed olive oil.

To support this statement I would refer to the greasy appearance presented by a piece of paper when the British Pharmacopœia plaster is spread, also to its great proneness to rancidity upon keeping, and to the following experiment:—

10 grammes of lead plaster of the London Pharmacopœia was thoroughly beaten with 5 grammes of hydrated carbonate of potassium, and treated to exhaustion with alcohol (·825), the measure being finally made to 1 litre.

The B. P. plaster was treated by precisely the same method.

The resulting solutions of potash soap (Clarke's soap test) were then estimated by a solution of chloride of calcium (= ·0001 gramme $CaCO_3$ to each c. c.).

I found that while 17 c.c. of the soap solution made from the P. L. plaster produced a perfect lather with 100 c.c. of the lime test, it took 18·5 c.c. from the B. P. plaster to produce a like result, showing that there was in the latter an insufficiency of litharge to convert the whole of the oil present into a lead soap; for had sufficient been present then the British Pharmacopœia plaster, containing as it does 69·6 per cent. of soap-forming material (oil) against 65 per cent. of the London Pharmacopœia, would have produced a soap test of as much greater strength as compared to that from the London Pharmacopœia plaster, as 69·6 : 65 = 6·6 per cent. stronger.

Of course I do not for one moment pretend that the proportions for lead plaster can be calculated, but if these figures mean anything, according to my view they prove that free oil is unmistakably present in the British Pharmacopœia lead plaster.

The questions before us then are these:—Is it desirable, knowing how prone olive oil is to rancidity after protracted boiling and exposure to air, to have any excess present in adhesive plaster?

Is it desirable to have a plaster as near neutral as possible?

Granted, that a plaster with a larger proportion of litharge than the B. P. directs is not as "sticky," in the first instance, as the B. P. plaster itself; but when once attached possesses sufficient adhesiveness to maintain itself and the surface to which it has been applied with rigidity,—is not such a plaster preferable to one that does not possess sufficient permanent adhesiveness, but soon becomes detached?

Is it desirable in the publication of a formula for lead plaster to insert such a one as is opposed to the usages of trade, which manufacturers of an adhesive plaster cannot use?

Is it not desirable to adopt a formula which is almost identical in the proportion of litharge throughout the world?

These are matters for discussion, and upon them I ask your opinion this evening.

The emplastra are not held in the esteem they were in the first half of this century, although the Committee of the proposed International Pharmacopœia would lead us to believe, from the number they purpose introducing into that work, that in some countries plasters are fashionable remedies.

Still it is, I imagine, advisable that while we are called upon to produce plasters, and notably lead plaster, the basis of so many others, we should prepare them in the most desirable form.

My own experience (and in this opinion I know I am not alone) is, that the simple formula of

Litharge . . . one part,
Olive Oil . . . two parts

would be the best under all circumstances for our national Pharmacopœia.

[*The discussion on this paper is printed at p.* 716].

THE ESTIMATION OF FAT IN MILK.*

BY EDWARD LAWRANCE CLEAVER.

The method of milk analysis now generally adopted by analysts for determining whether milk has been adulterated by the admixture of water, is based on the fact that the amount of "solid matter not fat" in milk is very constant, and therefore all samples of milk in which the "solid matter not fat" falls below a recognized standard are to be considered as admixed with water, regard, of course, being paid to the total solid matter in the case of milks exceptionally rich in fat.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, on Wednesday, March 3, 1875.

The determination therefore whether milk has or has not been adulterated with water depends mainly on the accuracy with which the fat has been estimated, and the object of this paper is to compare the processes now in use for that purpose, to point out their defects, and to provide a means by which those defects may be greatly, if not entirely, remedied.

The processes in general use are as follows :—

1. A large quantity of milk, say 1000 grains, is evaporated to dryness with constant stirring, in order to prevent the residues from adhering to the sides and to obtain them in a granular condition. These residues are then transferred to an apparatus similar to that used for the estimation of oil in cake, meal, etc., and the operation is conducted in the usual manner. This process is amongst the most accurate, but the time occupied in its performance constitutes a great objection.

2. A smaller quantity than the preceding, say 200 grains, is evaporated to dryness as above, weighed, and the residue macerated with cold ether ; this ether is then poured off, evaporated to dryness, and the resulting fat weighed, or the fat is calculated from the loss in weight sustained by the solid matter. The objections to this process are numerous. Firstly, the fat cannot be extracted from milk solids by cold ether, especially when they are in the hard granular condition produced by evaporation to complete dryness. Secondly, the ether, unless filtered, will hold in suspension innumerable fine particles of the solid matter, and although the ether may appear perfectly clear when poured off, yet, on being left at rest a short time, a deposit will be found upon the bottom of the containing vessel. Thirdly, on drying the residues the ether mechanically enclosed causes them to decrepitate and fly about. The evaporation of the ether is also worthy of some attention, for when ether is evaporated over a water-bath, the ether is almost certain to enter into ebullition, and the bubbles of vapour in escaping carry off with them a large quantity of the fat.

3. The milk is evaporated to a pasty condition and treated with warm ether, the ether poured off, evaporated to dryness, and the resulting fat weighed. This method is open to the same objections as the preceding.

4. The method proposed by Mr. Horsley, of Cheltenham, is the next I have to consider. It is based on the principle that the butter fat can be dissolved out from milk by agitation with ether, and can be set free from solution by the addition of alcohol, its volume is then ascertained and the weight calculated from that volume. There are, however, some objections to this method. 1st—The precipitate caused by the addition of the alcohol forms a mass which encloses the fat mechanically within it, and therefore prevents it from rising to the surface. 2nd—If the temperature be low, the globules of fat solidify and these solid particles do not rise so readily as when liquid, and the fat takes some hours to completely rise to the top of the liquid. These two difficulties can be, however, overcome by adding 5 or 6 drops of a 10 per cent. solution of caustic soda to the milk before agitation, and after the alcohol has been added placing the tube in warm water in order to keep the fat in a liquid condition.

When making use of this method at first, I found that I always obtained a higher percentage of fat than by other plans, and thinking, therefore, that the instrument might have been improperly graduated I proceeded to ascertain if that was the case. I found that when a known amount of pure dry butter was placed in one of these tubes and the operation performed as with milk, the volume of fat set free exactly corresponded with the weight added, but that if, when operating on milk, the fat was removed from the tube by a pipette, and estimated by evaporation and weighing, I never obtained the quantity indicated by the volume ; and I am, therefore, led to the conclusion that, although the instrument has been graduated correctly when butter has been taken as the standard, yet owing to the condition in which the fat in milk is (namely, that of an emulsion), a larger quantity of ether is retained by the fat, and consequently the amount indicated is too high ; each division, in fact, should correspond to 3·8 grs., by weight, of fat, instead of 4·15 grs. Further experiments on this point are, however, perhaps desirable. The points I have established during my experiments on the above processes are as follows :—

1. *Cold ether* will not dissolve out the entire amount of fat from dry milk residues.

2. *Boiling ether* will not dissolve out the entire amount of fat from milk residues when in a pasty condition.

3. *The residues should be in a state* of fine powder, and must be boiled three or four times with successive portions of ether in order to thoroughly extract the fat ; the ether being always passed through a small filter before evaporating.

4. *During evaporation care* should be taken not to allow the ether to enter into ebullition.

Bearing these points in mind, I have endeavoured to devise a process in which the loss of fat is reduced to a minimum. It is as follows : Ten grammes of milk, or 10 cub. cent., are put into a small dish and evaporated to complete dryness, constantly stirring towards the end of the process with a glass rod enlarged at the end so as to break up all small lumps to obtain the residues in a fine powder. The residues are then transferred to a long narrow tube ; one of Mr. Horsley's tubes answering well for the purpose. The dish is then rinsed with ether and the ether added to the residues in the tube.

A piece of damp cloth is held round the top of the tube, the mouth being closed by the thumb of the operator. On immersing the tube in a water-bath the ether begins to boil, and the pressure can be so regulated by the thumb of the operator that the ether may be kept in gentle ebullition, although at a temperature considerably above its boiling point. The ether is then poured off through a filter, and the operation repeated several times, not less than four, as I have frequently, in the *fourth* treatment, obtained as much as one-eighth part of the whole quantity of fat previously extracted. The filter is then washed with a small quantity of ether, and the evaporation proceeded with. This I effect by directing on to the surface a current of air from a bellows or foot blower, either warm or cold ; completing the operation by a few minutes over a water-bath. Two fluid-ounces of ether can easily, by this means, be evaporated off in ten minutes without any fear of loss by ebullition. By this method I am enabled to extract from ·5 to 1 per cent. more fat than by other methods ; and, in fact, to nearly approach the amount shown by Mr. Horsley's lactometer ; and it will, in practice, be found to be very little more trouble than the ordinary methods, whilst on the score of accuracy, it leaves but little to be desired.

[*The discussion on this paper is printed at p.* 718.]

NOTES ON SOME UNITED STATES' DRUGS.*

Bitter Principle of Wild Cherry Bark. By John L. Williams, Ph. G.—The author did not succeed in completely isolating the bitter principle of wild cherry bark. The following process gave the most satisfactory results:—

An aqueous infusion of the bark was concentrated, filtered, mixed with an equal volume of alcohol, and, after standing for twelve hours, filtered. The liquid was treated with milk of lime, the filtrate evaporated to a syrupy consistence, a large quantity of alcohol added and the filtrate evaporated. The residue was exhausted with boiling alcohol, which on spontaneous evaporation yielded a transparent brownish residue, of a somewhat gelatinous aspect. It possessed a bitter taste, was insoluble in ether, soluble to a limited extent in water, more soluble in alcohol, particularly if heated. Concentrated sulphuric acid coloured it brown red; cold nitric acid had but little effect upon it.

Actæa alba, Bigelow. By William Dilmore, Ph. G.—This plant is popularly known under the name of white cohosh, white beads, Noah's ark, and necklace weed. The rhizome with the rootlets, which is the portion medicinally employed, has at first a sweetish-bitter, afterwards acrid taste, followed by a peculiar irritating sensation upon the fauces.

The distillate with water possessed the odour of the root and a slight taste. The infusion and decoction were found to contain albumen, gum, sugar, starch, and extractive, but neither tannin nor gallic acid. The alcoholic tincture contains two resins having the acrid taste of the root, both of which are soluble in alkalies and reprecipitated by acids, while ether dissolves one only. After the concentrated tincture has been precipitated by water, and the resins filtered off, the liquid froths considerably on agitation, and contains a principle analogous to saponin, which may be obtained in a still impure condition by evaporating the liquid, extracting the residue with diluted alcohol, decolorizing by animal charcoal, and agitating with ether, which on spontaneous evaporation yields a brown, translucent and brittle substance, having a bitter and acrid taste. It is soluble in alkalies, water, diluted and strong alcohol, assumes with warm sulphuric acid a rose colour, changing to purple, and finally violet.

Cypripedium acaule, Lin. By H. Northam Bryan, Ph. G.—The attention of the author was attracted to this plant from observing persons engaged in collecting its subterraneous portion, and, upon inquiry, being informed that it was to be used as an emmenagogue; afterwards, the effects of this rhizome with rootlets were observed, tested in several instances with apparent success. The drug, when fresh, has a rather strong and heavy odour and a bitter taste, and in the dry state is of a dark-brown colour.

Only a limited quantity of the material could be procured for experimental purposes, from the results of which it appears that it yields, on distillation with water, a minute quantity of volatile oil; to carbon bisulphide and to alcohol, some resinous matter, which is wholly soluble in ether, and to ether about ten per cent. of solid matter, which is only partially dissolved by alcohol, the insoluble portion giving a blood-red colour with sulphuric acid. The presence of tannin, sugar, and starch was likewise proved.

NATURAL PRODUCTS OF PERSIA.

In a paper printed in the last number of the *Journal of the Linnean Society*, "Some Observations on the Vegetable Productions and the Rural Economy of the Province of Baghdad," Surgeon-Major W. H. Colvill gives some interesting particulars of the flora of the strip of alluvial land watered by the Euphrates and the Tigris, and lying between the Arabian desert and the tableland of Persia, once the garden of the world, but now possessing an extremely poor flora; after a diligent search the writer could not succeed in collecting more than 100 species. There is in this district not a hollow to shade a plant or retain moisture; there is no land of intermediate character between the dry level plain and the reedy swamp. It produces grapes, but remarkable neither for appearance nor variety: the chief grains are barley and wheat, three varieties of each. The same land yields also, when irrigated, a summer crop of onions, beet-root, turnips, melons, cucumbers, brinjals, and bamias (*Abelmoschus esculentus*). Three varieties of rice are grown, as well as millet (*Panicum miliaceum*) and ethera (*Sorghum vulgare*) in small quantities. The only palm is the date-palm, and that requires very careful cultivation, and is commonly grafted, it being very rare to find one that has been grown from seed. The sex cannot be ascertained till they are a year old. There are at least twenty-six different varieties, the best coming from Il Hissah and Shitolah, oases in the desert watered by perennial springs. Among Rhamnads the Mabk is doubtfully indigenous; it is the largest tree in the country, flowering twice in the year. At the end of July it produces fœtid flowers and fruit ripening in September or October, but full of worms and quite uneatable; in February it again produces flowers, which are scentless; the fruit, the size of a large filbert, ripens in April, when it is considered to be in perfection, having much the flavour of a wizened apple. The tamarisk forms the chief part of the brushwood which fringes the banks of the rivers, and is the chief source of charcoal and household fuel. It does not appear to produce manna. Of plants yielding drugs there are only two in the whole country. One of these is the caper-bush, from the young shoots and delicate leaves of which a decoction is made and taken as an aperient and anthelmintic, being used with good effect in cases of round worm. Another plant which the writer was unable to determine was made use of by burning the root and branches, the dark ash being employed in medicine and soap-making. It consists chiefly of soda or potash, and is called "kali," obviously the origin of our word alkali.

* Abstracts from Essays presented to the Philadelphia College of Pharmacy; from the *Amer. Journ. Phar.*

COLOURED INKS.

The following recipes are stated by the Boston *Journal of Chemistry* to have been well tested and to be recommended by good authorities as preferable to the solutions of aniline dyes which are now so extensively used as coloured inks:—

Green.—Two parts of acetate of copper, one part carbonate of potash, and eight parts water. Boil till half is evaporated, and filter.

Blue.—Three parts Prussian blue, one part oxalic acid, and thirty parts of water. When dissolved, add one part of gum-arabic.

Yellow.—One part fine orpiment, well rubbed up with four parts thick gum-water.

Red.—With the aid of a gentle heat, dissolve four grains of carmine in one ounce of aqua ammonia, and add six grains of gum-arabic.

Gold.—Rub gold-leaf, such as is used by bookbinders, with honey, till it forms a uniform mixture. When the honey has been washed out with water, the gold powder will settle at the bottom, and must be mixed with gum-water in sufficient quantity.

Silver.—Silver-leaf treated in precisely the same manner gives a silver ink. Both these inks may, when dry, be polished with ivory.

Black.—Three ounces crushed gall-nuts, two ounces crystallized sulphate of iron, two ounces gum-arabic, and twenty-four ounces water.

White.—Fine French zinc-white, or white-lead, rubbed up with gum-water to the proper consistency.

The Pharmaceutical Journal.

SATURDAY, MARCH 6, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SALE OF FOOD AND DRUGS BILL. DEPUTATION TO THE LOCAL GOVERNMENT BOARD.

In pursuance of the instruction given by the Council the Parliamentary Committee met on Thursday morning, and the President, the Treasurer, Messrs. Greenish, Owen, and Sandford, accompanied by the Secretary, proceeded to the Local Government Board and had an interview with Mr. Clare Read and Mr. Lambert, the Permanent Secretary to the Board.

It was emphatically represented to these gentlemen that one of the chief objects of the Pharmaceutical Society from its commencement had been to secure greater purity in drugs, not only by drawing attention from time to time to adulterations which might be discovered, but also by advancing the education of chemists and druggists, thus rendering them better able to judge of their quality; that the Society would in no way lend itself to the perpetuation of such frauds as the Adulteration Act was intended to prevent; but that so many cases of injustice had arisen in carrying out the present Act, either through its defective wording or misinterpretation, that they felt bound to thank the Government for the evident spirit shown in the new Bill to render the law less obnoxious in its operation.

It was pointed out that the proposed amendments appearing on the notice paper of the House of Commons included one to erase the word "knowingly" in almost every case in which it occurs in the Bill. The injustice of doing this, so far as regards the retailer, was urgently represented, and great stress was laid on maintaining the principle expressed by that word in the Bill. The word should be properly interpreted *fraudulently,* and it should certainly be open to an accused party to prove that he had not been guilty of fraud. He might do this in various ways; one being a *proof* that he bought his drugs in the best market, at a fair price, and with a reasonable belief in their purity; and *proving* this he should be regarded as an innocent man.

It was further urged that the difficulty of discovering some adulterations was so great that even skilled analysts varied respecting them, and that it was not fair, therefore, to convict an ordinary dealer on an *implied* knowledge of them. Attention was also drawn by the deputation to the necessity of great care being taken in the appointment of analysts, that it was not always the most celebrated chemist who would be the most trustworthy public analyst for the purpose of the Act, inasmuch as a certain knowledge of the ordinary condition of articles was required to enable a man to judge fairly.

The question of penalties was discussed, 50*l.* for a first offence, and six months' imprisonment *with hard labour* for a second being considered excessive.

Certain amendments were suggested by the deputation in various parts of the Bill where words occur which would materially interfere with the every day compounding of drugs and possibly with the manufacture of "proprietary medicines."

Both Mr. Clare Read and Mr. Lambert treated the deputation with the greatest courtesy, took notes of the suggestions offered and promised to give full consideration thereto.

On Thursday evening the House of Commons went into Committee *pro formâ,* but immediately reported after ordering the Bill to be reprinted, and as amended it is to be recommitted on Friday, the 19th of March.

THE HULL "MORNING TONIC" CASE.

On behalf of the Commissioners of Inland Revenue, the Collector of Inland Revenue at Hull has waited on Mr. Travis, the magistrate who heard the recent case against Mr. Staning for an alleged breach of the law in the sale of "morning tonic," and informed him that having regard to the able and satisfactory exposition of the law on the subject given by Mr. Travis in court, the Commissioners acquiesced in his desire that the case should now end.

EFFECT OF JABORANDI ON THE TEMPERATURE OF THE BODY.

In the description by Mr. Martindale of the effects following the taking of a dose of infusion of Jaborandi, he stated that the temperature was not taken, but that a slight shivering was experienced. This evidence that the drug does not act by increasing the temperature is confirmed by some notes, placed at our disposal by Mr. R. Cory, Surgeon, of Carlisle, who swallowed the infusion and dregs of half a drachm of Jaborandi, and then carefully noted the varying temperatures in the right and left axillæ. The dose was taken at 12.15 a.m., when the average temperature of the two axillæ was 35·2°. In fifteen minutes the temperature had risen to 36°, the highest point reached; it then gradually fell to 35·15, the lowest point, at 1.30 a.m., and by 2.15 a.m. it had risen to 35·35. The pulse increased from 60 at 12.15 a.m. to 74 at 2.0 a.m., at which time the secretion of saliva seemed to be diminishing; the whole quantity expectorated amounted to five ounces. The drug had no diaphoretic or diuretic action on Mr. Cory, neither did it affect his sight or pupils; probably, he thinks, because the dose was not sufficiently large.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

In connection with the above Association, arrangements have been made for holding afternoon classes in the various subjects required by the Board of Examiners, the afternoon being thought to be a convenient time for many persons who are engaged in retail business. An examination is to be held at the end of each term, and prizes will be awarded to the students most distinguishing themselves in the respective courses. Particulars may be obtained by application to the President of the Association, Mr. T. Barclay, 17, Bull Street, Birmingham.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, March 3rd, 1875.

MR. THOMAS HYDE HILLS, PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Frazer, Greenish, Hampson, Owen, Radley, Rimmington, Robbins, Sandford, Savage, Schacht, Shaw, Sutton, and Williams.

The minutes of the previous meeting were read and confirmed.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Chamberlain, Arthur Garratt...Rugby.
Corks, Arthur Brownhill.........Worthing.
Stacey, Henry George ....London.
Stamps, Frederick..................West Bromwich.

Chemists and Druggists.

Campkin, Algernon S. ....Cambridge.
Green, Isaac ....Birmingham.
Hall, Thomas... ....Lowestoft.
Spencer, William George.........Wimbledon.
Wood, Jacob ....393, Commercial Rd.

Mr. Henry Walker, of London, an Associate of the Society before 1842, was elected a Member.

ASSOCIATES.

The following having passed their respective examinations were elected "Associates in Business" of the Society:—

Minor.

Barton, William ....Stoney Stratford.
Bracher, Walter Phipps ....33, Euston Square.
Evans, Evan Thomas ....Mountain Ash.
Llewellyn, John ....Cowbridge.
Mellor, Thomas.....................Elton, Bury.
Price, James ....Llangollen.
Sneath, Thomas Dixon .. ..Newark-on-Trent.
Warrior, Henry........................Northallerton.

Modified.

Barnard, Alfred Philip.............Stamford Hill.
Bathe, Robert Samuel ....Notting Hill.
Lambert, George Pitt ....Maidstone.
Martin, Amelius Hare.............Edgware Road.
Mason, Frederick ....Rotherham.
Pearson, Edward ....Nottingham.
Stevenson, Richard Walter......Tetbury.

The following having passed their respective examinations were elected "Associates" of the Society.

Minor.

Attwood, Henry Ernest ... .Edinburgh.
Fletcher, Howard Bennett ......Leicester.
Gilkes, Frederick George.........Banbury.
Moon, Murray James ....Godalming.
Morrison, William Hay ....Aberdeen.
Outred, Thomas Benjamin ......Colchester.
Pell, John ....Market Harborough.

Rogers, Stephen ....Manningtree.
Senier, Alfred, jun. ....Finsbury Park.
Senier, Harold ....Finsbury Park.
Thornber, William .... Preston.
Wills, Andover Vincent ....Blaenavon.
Young, Pelham Charles ....Salisbury.

Several persons were restored to their former status in the Society on payment of a fine and the current year's subscription.

The name of Joseph Charles Nicholls, of 49, Chippenham Road, Harrow Road, was ordered to be restored to the Register of Chemists and Druggists.

Finance.

The report of this Committee was read and adopted, and various accounts were ordered for payment; amongst others, £113 for furnishing and fitting the rooms of the North British Branch, and a sum of £100 for the current expenses of the Branch.

Auditors' Report.

This report, with the financial statement for the past year, was presented.

Mr. Williams said that during the year it appeared that they had received altogether £9500, and had spent it all, allowing for £200 owing to the builders, within £600, which was running rather close. There were certain items which looked rather startling; for instance, the cost of examinations had increased by £450. The Journal, on the other hand, was paying a little better, as it only cost £866 instead of £1000, without, of course, reckoning anything for the cost of the Journals supplied to the members. He hoped that in time the Journal would again show a profit as it did when it was issued monthly, not that he meant to say they did not get value for the £800, but that was the amount required to be provided for.

Mr. Greenish said if the cost of the Journals supplied to persons connected with the Society were charged against the general account, there would be a profit shown.

Mr. Williams continued—According to the Financial Statement, there was only apparently £168 spent on the library, but to that sum must be added the £245 salary of the Librarian and his assistant, which thus brought up the real cost to £413; the general charge for clerks and servants being of course diminished by a similar amount. He thought, therefore, that the Council had acted liberally towards the library this year.

Mr. Savage said there were one or two points which struck him as worthy of remark, and he thought their thanks were due to the Secretary for the admirable details which he had supplied. It appeared that whilst there had been an increase of the Society in the aggregate from pharmaceutical chemists and chemists and druggists to the number of 336, when they came to look at examination statistics, they found that, although 365 more candidates presented themselves this year than in the preceding, there was a diminution of 271 in the number which passed.

Probably the year might be taken as an exceptional one, in consequence of many crowding in to avoid the more strict examination which was expected. The expense for furniture and fixtures, and the house expenses had increased, and also those for repairs and alterations, but that probably arose last year in part from the extensive alterations made in the library.

Mr. SCHACHT said the great fact which struck him was the absence of a certain line in this balance-sheet which appeared in the previous year—namely, the purchase of Government securities to the amount of £2,500. Of course there was something on the contrary side in that year, bringing the amount actually invested to something like £1,500, but on the present occasion there was nothing of the sort. This was worthy of consideration at a time when they were supposed to have reduced their expenses in the teaching department very considerably. These expenses seemed to be distributed over a number of different items, all of which were gradually increasing.

The SECRETARY said he was glad this fact had been called attention to, because it would be necessary to look at it seriously in coming years. The income was now approaching £2,500 from voluntary subscriptions of members who were pharmaceutical chemists and chemists and druggists. The latter description of members would, in course of time, cease to exist, and that source of income, which was now £850, would be cut off. The pharmaceutical chemist members also would materially diminish.

Mr. SANDFORD asked whether there would not be the associates in business coming in to take the place of the members who were dropping off.

The SECRETARY said he did not think they would make up for the loss of members.

Some further discussion ensued as to the amount which had been expended on the alterations and repairs of the Society's premises.

Mr. WILLIAMS then said the most striking increase in the expenditure was in the cost of the examinations, which, in fact, just balanced the amount saved on the school.

The SECRETARY said he had had a statement prepared showing the amount expended from the year 1868 on any particular item for each year. With regard to the house, it was in a very good condition, and would not want much spent upon it for several years to come.

Mr. WILLIAMS was quite satisfied the Society had done well in spending money on its own premises. They had now been made, what they were not formerly, properly adapted to the requirements of the Society.

In reply to questions as to the financial position of the Society,

The SECRETARY said that the actual difference between the receipts and expenditure for the past year was about £300 to the Society's credit. He did not see any probability of a larger surplus for the next seven years, and therefore he thought they should look forward to a diminished income, and cut down the expenses as much as possible.

Mr. WILLIAMS thought it desirable to encourage young men to become members, or associates. Unfortunately, a great number of those who took advantage of the establishment did not connect themselves with the Society. He knew of a case in which a Bell Scholar, who had actually received great benefits from the Society, was not now in any way associated with it by membership or otherwise. He thought that students should be encouraged to join the Society rather than have all the advantages of the Society given them without the payment of any subscription.

The SECRETARY said there was a difference of upwards of £1100 between the receipts from the examination in 1874 and 1873, owing to the greatly increased expenditure. He thought they would be obliged eventually to increase the examination fees.

Mr. FRAZER said he believed, on the contrary, that they would have to be reduced. He did not grudge the outlay which had been made on the Society's premises, because it was not thrown away, but they had value for their money. There had been certain exceptional expenses during the past year, such as the deputation to Scotland, that to St. Petersburg, and the Conference in August, and these matters would not occur again. With regard to the North British Branch, he was in Edinburgh the previous week and was delighted to see the state the Society's rooms were now in. It thoroughly convinced him of the wisdom of the Council in making the recent change there.

Mr. GREENISH thought it would be very much better if so large a proportion of the examination fee were not returned to the unsuccessful candidates. It was generally admitted that during the past year a great number of candidates had come up merely as an experiment, who, although paying three guineas each, had two guineas returned to them on their rejection.

Mr. RADLEY thought it would be a great improvement if the accounts included a statement of the liabilities as well as the income of the Society, simply for the use of the Council, and for comparison. He would move that this be done.

Mr. HAMPSON seconded the motion. It had been done on one or two occasions, and he was under the impression it would be continued.

Mr. BETTY said he should be sorry to see the expense incurred in calling in the assistance of a professional accountant thrown away by not continuing the system which he recommended, and which had been adopted as a good one.

The SECRETARY said the balance-sheet had not been produced this year, because it was useless to present it before the auditors, as they would not pass it, but it was already prepared in detail, in accordance with the accountant's recommendation, and a copy of it should be supplied to each member of the Council, or the Finance Committee might examine it for themselves. The balance-sheet would be in the hands of every member of the Council in the course of three or four days.

After some further conversation Mr. Radley's motion was withdrawn, and it was resolved that the report be received and adopted.

BENEVOLENT FUND.

The Committee reported that it had met, and having considered several applications for relief, recommended that the following grants be made:—

15*l.* to the widow of a pharmaceutical chemist, late of Brighton, having three children dependent upon her. It was recommended that the money should be placed in the hands of a gentleman named, to be expended weekly.

10*l.* to the widow of a member, late of London, aged 59

10*l.* to the widow of a registered chemist and druggist at Bermondsey.

10*l.* to a registered chemist and druggist at Wells, Norfolk, who had been suffering for some time from spinal paralysis, and was entirely dependent on his friends. (*Second grant.*)

10*l.* to a chemist and druggist who had been for two years an unsuccessful candidate for an annuity. (*Second grant.*)

10*l.* to the widow of a chemist and druggist at Birmingham, having three children dependent upon her.

Another case was stated to have been deferred for further inquiries, the letters of inquiry sent not having been answered.

Mr. OWEN said he understood the latter application was altogether rejected, as the party applying was evidently not a proper subject for relief from the Benevolent Fund.

Mr. GREENISH said the minute was quite correct, because the information required had not been sent. The application would no doubt be formally disposed of at the next meeting of the Committee.

With reference to the £10 placed in the Secretary's hands last month for expenditure if his inquiries were satisfactorily met, he reported that he had for the present withheld the money.

The report and recommendations were unanimously adopted, and the name of one of the above mentioned applicants for relief was placed on the list of approved candidates for an annuity.

Library, Museum, and Laboratory.

The Committee recommended the purchase of the following books for the library:—Griffith and Henry's 'Micrographic Dictionary,' third edition; Flückiger and Hanbury's 'Pharmacographia,' a third copy. The circulation of books during the past month had been—in town, 134; in the country, 47, to 26 places. The attendance in the library had been on the average, during the day, 13·2; evening, 9·5. Attendance in the conversation room, 6·85.

The Committee had considered the possibility of allowing applicants for books to have more than two volumes at a time; and also the question of admitting associates to the privilege of borrowing books, and recommended that the library regulations be slightly altered. It did not, however, recommend that associates be allowed to borrow books on their own responsibility. The alteration in the rules consisted in erasing the words from Rule 5 applying to valuable works, distinguished in the catalogue by an asterisk, "except by special permission of the Committee," and inserting a fresh rule as follows:—"If, under special circumstances, more than the stipulated number of volumes, or the loan of any volume marked with an asterisk in the catalogue, be required, application must be made to the Librarian, who should submit the same to the Committee.

Professor Attfield had reported that there had been 74 entries in the laboratory since the commencement of the session, 53 pupils now working. He had also submitted to the Committee an altered form of advertisement of the School of Pharmacy.

The Curator of the Museum had reported that a further portion of the catalogue was ready for the printers. The attendance in the museum had been on the average, in the day, 13; evening, 3. The average of attendance by gentlemen holding tickets was 2.

Mr. Schacht was sorry the Committee could not have made a little more concession than the small one now offered. It was simply a condition which greatly limited the usefulness of the library. He suggested, that if it was not thought desirable to leave the discretionary power entirely in the hands of the Librarian, a reference to the President would be sufficient instead of waiting for a meeting of the Committee.

Mr. Williams thought any one wanting books of the class referred to, would want them for a special purpose, and would not be in a particular hurry for them.

Mr. Sutton said he had been obliged to buy a book, because he could not get the information he wanted from it in the time allowed by the library rules.

Mr. Greenish remarked that the time might have been extended by application to the Librarian if the book had not been previously engaged by another member.

Mr. Baynes understood Mr. Schacht to refer to books consisting of more than two volumes, and he had known a case in his own experience where certain information had been wanted from a work in several volumes, and it was not known in what portion it would be found. In such cases the delay requisite for obtaining the permission of the Committee would render the privilege useless,

Mr. Robbins said the Librarian was frequently applied to for a book containing particular information, and he was in the habit, in such cases, of selecting the volume containing the desired subject. If, in special cases, a member wanted more than two volumes he could get his next neighbour to join with him and ask for the remaining volumes.

Mr. Baynes said it was much the better to do the thing openly and properly than in the way which had just been suggested.

The President suggested that the application should be made to the Secretary instead of to the Committee.

Mr. Betty said the Secretary could report the matter to the next Committee meeting, so as to keep things regular.

Mr. Williams supposed no one would think of sending for the whole eighteen volumes of Gmelin's 'Chemistry:' if he did was the Secretary to send them?

Mr. Schacht said no one would send for such a work unless he really required it, because he would have to pay half the carriage; but these books were just those for which reliance was placed on lending libraries.

Mr. Sandford then moved that the report and recommendations of the Committee be received and adopted, with the exception that the appeal should be to the Secretary instead of to the Committee, the Secretary being empowered to authorize the sending of more than one volume or of books marked with an asterisk, at his discretion. There was one other matter which he wished to mention, viz., the introduction into the advertisement of the School of Pharmacy of the words "during their term of study," in the sentence stating that students unconnected with the Society might obtain, on application to the Secretary, tickets of admission to the library and museum. The words seemed to imply that such students were entitled as of right to a ticket of admission extending over the whole of their term of study; whereas he considered that there was a danger, if such were the case, of many of the students never connecting themselves with the Society.

Mr. Schacht thought young men who attended the laboratory were entitled to find, in connection with the Institution to which they paid their fees, the text-books at least of the science which they were about to study. Now there was no other library in connection with the laboratory, and therefore he hoped there would be no hindrance put in the way of students making use of the Society's library.

Mr. Williams said it was simply a question whether it should be a matter of right or of privilege. Continuing it, as it had been, a matter of favour, obliged the student to apply periodically to the Secretary for a ticket, and gave the Secretary an opportunity of conversing with him and urging him to join the Society.

After some further conversation the motion of Mr. Sandford was unanimously agreed to.

Registrar's Report.

It was resolved that the report and statistics (see opposite page) furnished by the Registrar should be published in the Journal and Transactions of the Society.

Annual Report.

The Library, Museum, and Laboratory Committee was requested to draw up the annual report.

House.

The Surveyor's report with regard to the protection of the premises against fire had been presented, and the Secretary had been requested to make further inquiries and report to the Committee at the next meeting.

The report was received and adopted.

Law and Parliamentary.

The report of this Committee stated that the solicitors had commenced proceedings against Mr. A. Fry, of 131, Matilda Street, Sheffield, for carrying on business as a chemist and druggist, he being unregistered. The defendant had paid the penalty of £5 and costs, and had been admonished as to his future conduct.

The Government Bill for the Amendment of the Adulteration Act had been discussed by the Committee, and two communications were read—one from the Liverpool Pharmaceutical Association, approving the principle of the Bill, and another from the National Chamber of Trade, asking if the Council intended to take any steps with regard to it.

Mr. WILLIAMS said, in considering the position which the Society should take with regard to the Bill now before Parliament as to the sale of food and drugs, it should be distinctly understood that they in no way wished to encourage adulteration; on the contrary, it was their strong desire to put an end to adulteration wherever it existed, and the Society had already done a great deal in that direction. Thirty or forty years ago adulteration existed to a very great extent, and one great motive for establishing the Society was to encourage purity in the sale of drugs, and its influence had been felt, perhaps, more in that way than in any other. The Society would not therefore oppose any Bill for imposing penalties on those who committed the crime of adulteration, but at the same time, it was felt that the Act, as it at present existed, caused great hardship in some respects. It was unfair in principle, because it punished the innocent in the attempt to get at the guilty. The law ought to punish those who were really the guilty persons; whereas a man who bought an inferior article and sold it in the same state, if a small amount of impurity were found in it, might be fined or punished. The present amended Bill, he believed, was one which would not pass in its present form, and in fact there were many clauses in it which opened the door to extensive adulteration and to undoing the good work which the present Act had done. The Council must therefore be very careful not to ask the Government to pass clauses which would support adulteration, whilst at the same time it should endeavour to assist Government in giving relief to the innocent trader, and securing him from punishment for that which was not his own fault. One suggestion had been that the retailer should be justified if he produced a written warranty from the wholesale dealer, but there might be difficulty in that way, the written warranty might be a mere invoice; say, for instance, in the case of arrowroot, which might turn out to be more or less adulterated, although the wholesale dealer might not have been aware of it. He would also suggest that very small amounts of articles, intended for analysis, should not be taken; it was not fair to the trade. Further, the sample taken should be divided, and sealed up at the time, in the presence of the parties. If questions could arise as to the truth of the analysis, there should be no doubt as to the second analysis being of the same sample as the first. In some cases, however, there had been some doubt on this point. With regard to the appointment of analysts, his opinion was not in accordance with that which the Bill recommended, viz., that they should be still appointed by small local bodies throughout the country. His own idea was that some half dozen properly appointed laboratories should be established in different centres, each under the superintendence of a well-paid chemist in whom public confidence could be reposed. He believed this would be more satisfactory in every respect.

Mr. RIMMINGTON said there might be some difficulty with regard to the suggestion for dividing the sample taken, and sealing it up. It might be done with parcels tolerably easily, but in the case of liquids it would be impracticable. He thought, therefore, it should be optional if the party requested it. With regard to wholesale houses, any house ought to know whether it was selling genuine arrowroot or not. He had had a great deal to do with the Adulteration Act, and it was true beyond a question that people who sold these things were often the victims of wholesale dealers. In cases where it could be proved that the retailer had been the victim of a fraud on the part of a wholesale dealer, he thought the magistrate ought to have the power of bringing that wholesale dealer before him. There might be some difficulty in carrying out such a provision, but that was really what should be aimed at. In his neighbourhood the magistrate advised every person who was fined to bring an action for damages against the wholesale dealer; but most of them were small tradesmen, and they simply compromised the matter by payment of the costs. There were two wholesale houses in his district who it was known had for years been selling pepper largely adulterated, and in consequence of their action retailers had suffered.

Mr. OWEN said the difficulty would be that there were very few retailers who did not deal with more than one wholesale house, and the wholesale dealer would not like to be made responsible for the article he supplied, when it might have been mixed with that coming from another quarter.

Mr. SUTTON said the only possible way in which this difficulty could be met was by a sample being taken at the time of each wholesale transaction and sealed up. This was evidently impracticable.

Mr. SANDFORD said that, according to the Government Bill, it was optional on the part of the persons supplying the sample to require it to be divided and sealed up.

Mr. WILLIAMS thought the party purchasing should be compelled to divide the samples.

Mr. SAVAGE said the party obtaining the article ought to know the quantity required much better than any Act of Parliament could provide. The analyst had power to ask for such a quantity as he thought sufficient for his purpose,—it might be a pound, an ounce, or a drachm. But if there was any defect it was from the analyst not asking for a sufficient quantity at the time when he sent to purchase the articles.

Mr. RIMMINGTON remarked that it was not the analyst who purchased.

Mr. SAVAGE said he meant the inspector.

Mr. WILLIAMS said if an analyst had a scruple of sulphate of quinine given him to analyse and was obliged to divide it into three portions, it would not be sufficient for his purpose.

Mr. GREENISH would like to know whether in the case of the adulterated pepper the retailers paid for it the price of genuine pepper.

Mr. RIMMINGTON could scarcely answer the question. There were some thirty tradesmen in Bradford and Leeds. These dealt with wholesale houses, who again bought from larger dealers, and they bought from the grinders, so that the article would pass through three hands before it reached the retailer. In all probability the retailer would have paid something like a fair price, but the wholesale man who supplied him probably did not.

Mr. SUTTON did not think analysts had anything to do with the price paid.

Mr. SANDFORD thought it was very important for a person accused of selling an inferior article to be able to prove that he had paid the best price, in order to establish his innocence.

Mr. SUTTON said there was no doubt of that, but he did not think the analyst had anything to do but to give his opinion as to whether the article was pure or not. Unfortunately many of the analysts asserted themselves in a way they had not the right to do.

Mr. WILLIAMS said one great difficulty was as to the meaning of the word "adulteration." He should define it as indicating that something was fraudulently added with an intent to cheat, not the mere presence of a thing either accidentally or only as an impurity. The mistake of the present Act, and of public analysts, was, that they confounded two different names or words as having the same meaning.

Mr. SUTTON said there was no doubt that some analysts considered themselves judge, jury, and everything else. He would suggest as likely to be useful that a few members of the Council should join with him on the following morning in an interview he, together with some members of the Society of Public Analysts, was to have with Mr. Clare S. Read on the subject of the present Bill.

Mr. SCHACHT said he could not possibly take part in any such deputation, because probably he should be in the unfortunate position of being almost alone in his opinions. He considered the present Act and the Bill now proposed as an illustration of the over legislation which had been going on for the last few years. The whole discussion had shown the enormous difficulty which surrounded such a position as this if they once attempted to apply it honestly and properly. His own opinion was that the buying public ought to be fined. Here was an opinion put forward that the responsibility ought to be taken from the retailer and put on the wholesale dealer, and from him to the importer, and possibly from him again to the manufacturer. But suppose you got to the manufacturer, what would be his defence? He would say that he would much rather manufacture a perfectly pure article, but he was required by his customers to produce something imperfect at a lower price. The wholesale dealer would say the same thing, and so it would go on; the retailer also would say he would much rather sell a perfectly pure article, but his customers insisted on having two penny worth of stuff for a penny, and thus he was obliged to supply them with an inferior article. That was the whole story. It was really the public who were to blame, and he thought they ought to pay the penalty of their misdeeds by being poisoned.

Mr. BETTY said the position taken up by Mr. Schacht was one which had no doubt a great deal to support it, but they had to deal not with the abstract idea of what was right or wrong, but with the actual facts at the present moment. In consequence of continued agitation and discussion there was at the present moment a Bill in the House of Commons to amend the present Act for the Adulteration of Food and Drugs, and what they had to do was to try and make the best of the Bill. This, he considered a most opportune time for the Society to entertain the question, because no definite opinions had yet been formed by the Legislature upon it, so that the opinion of the Council might exert some influence. He was very much pleased, and so was everyone having any practical knowledge of the subject, with the wise course the Government had adopted, and with the spirit in which the Bill was framed, namely, on the recommendation and almost in the words of the Select Committee of the House of Commons, which had examined witnesses on the subject. On important points justice had at last been done in this most intricate matter. The word "knowingly" was of the utmost importance. He did not think it could be retained in every instance, but it must be kept in so as to protect the retail dealer. The 25th clause, which provided that the retail dealer, being sued, could plead whether he knowingly or unknowingly had sold the adulterated article, by giving the source from which he obtained it, appeared to him common sense and justice. He hoped the Government would be prepared to abide by that principle, for it would be impossible for the retail dealer to be his own analyst with regard to every article brought before him for sale. He believed the Government were prepared to abide by the spirit of this Act, and not to allow the seller to be prosecuted when he could prove that he was not knowingly selling an article which had been mixed. That was a most important clause, as was also the 25th and, if it were carried, chemists and druggists would have no cause of complaint. As to how it was to be carried out he was not then prepared to say. The warranty might be simply the invoice, or a label stating that the article was pure; that would depend on the usage of the trade. But if a wholesale firm knew it would be liable to be included in a prosecution for any article sold to a retail dealer, he thought it would insure purity at the source, and thus relieve the retailer from the responsibility, supposing he had given a fair price, and that if the retail salesman were put in the same position, with regard to the wholesale dealer, that the public stood in with regard to the retailer, any practical difficulty in the working of the Act would be overcome.

Mr HAMPSON was of opinion that if there had not been previous legislation on this question, the present Government would not desire to initiate it, but they were in difficulty with regard to the previous Act, which they wished to make less objectionable, and that had led to the introduction of the new Bill. It was a most difficult question, however it was looked at, and it would be found utterly impossible to frame any Bill which was satisfactory. His own opinion was that such special legislation was objectionable, believing it often did more harm than good, but they must take things as they were, and, as a Council, they should endeavour to help those who desired to make the Bill as little objectionable as possible. Some of the penalties he thought much too heavy, and likely rather to defeat the ends of justice instead of bringing about convictions. He also thought with Mr. Williams that the samples should be sufficiently large to allow division. He should presently move the following resolution:—

> "That the Parliamentary Committee be requested to watch the progress of the Sale of Food and Drugs Bill, to prevent the introduction of objectionable clauses into the Bill. They are also requested to urge the insertion of a provision for properly testing the competence of analysts appointed under the Act."

The Bill as it stood would necessitate the appointment of a large number of analysts, and as Government were legislating to this extent that a person might suffer imprisonment and loss of character and position upon the opinion of a public analyst, he thought it was their duty to see that only proper persons were appointed. The truth was that the proceedings of some of these gentlemen had brought considerable discredit upon the working of the Act, and there was no guarantee that these numerous analysts to be appointed would be efficient. It struck him as most anomalous that persons who were to carry out the comparatively simple trade of chemists and druggists were subjected to examination, but the analyst who took into his crucible or scales the reputation of a respectable tradesman was not tested in any way as to his capacity for his office. He thought there should be something like a college of chemistry or some society which should grant diplomas in chemistry so that the various councils and public bodies throughout the country should have something to indicate to them that they were employing proper persons.

Mr. Greenish thought the Bill would be much simplified if the provisions with regard to food could be kept separate from those with regard to drugs, many which were applicable to one being quite inapplicable to the other.

Mr. Frazer quite agreed as to the extreme difficulty of this question and as to the fact that many hardships had arisen under the present Act, but he attributed that not so much to the law itself as to its administration. On the other hand, it had produced an immense deal of benefit to the public. For instance, in Glasgow, the late detection of lead in soda-water had caused great disturbance, and the evil had now been remedied at a great expense in almost every manufactory in Glasgow, but this had only been brought about by the action of the public analysts. There were many articles of dietary as to which the public had been greatly benefitted, and he thought they ought to continue to keep the benefit of the Act. The present Bill as it now stood was very imperfect; the Select Committee, he believed, having been overweighed by manufacturers, and the Bill, therefore, tended to protect the fraudulent dealer, and not the public in whose interest it professed to be framed. His own view was rather in accordance with that put forward in the Medical Press and Circular to the effect that the only honest method of dealing with these matters would be to allow traders to sell anything they liked so long as it was not injurious to life, but to force them to state honestly the true constituents of what they sold. Rather than pass the present Bill he should prefer to abolish the old Act and fall back on the common law, which punished imposition or misrepresentation; whereas, if the present Bill became law, he might sell scammony containing three-fourths of flour with impunity, simply because it did not contain anything injurious to health. If any resolution were passed, he should prefer one, though he did not suppose it would find a seconder, to the effect that the present Act had tended greatly to the protection of the public, and that the present Bill would lessen that protection. Any hardships which had arisen under the present Act he believed to have arisen more from its administration than its principle.

Mr. Robbins had almost hoped that he should have heard from the Council that drugs were not adulterated so largely as they formerly were. He must say the last Act of Parliament had not made the slightest difference to anything he had in his establishment. The truth was they did not get drugs of equal value in different establishments, but every man sold an article according to his class of customers; where a man could get full price he sold the best, and in that way he got a good reputation. There was a great deal of difference in drugs undoubtedly, but not generally arising from adulteration. For instance, a merchant who received a case of rhubarb picked out the choicest pieces and sold them at the highest price; then he picked out the second quality which he sold to a second class of dealers; and then he had a lot of comparative rubbish left, but which he still considered pure rhubarb, and certainly it could not be considered adulterated. The same with carbonate of soda. There were one or two firms who had a reputation for selling a very fine article, and the better class of dealers always kept it; but other manufacturers supplied carbonate of soda at about half the price, and though it was not quite so pure, no one could say it was adulterated.

Mr. Williams objected to the last clause in Mr. Hampson's resolution, for he thought many first rate chemists would decidedly object to submitting to any examination.

Mr. Owen said there was no examination mentioned.

Mr. Betty thought the clause was very important, and should be left in.

Mr. Sandford suggested that the Parliamentary Committee should meet the next morning to consider the amendments of the Bill which would then be printed.

The Report of the Parliamentary Committee having been adopted, and Mr. Hampson's resolution being put,

Mr. Williams again objected to the latter clause.

Mr. Schacht said he should particularly like those gentlemen who attended as a deputation to Mr. Clare Read to point out that the Bill would sanction the appointment of a number of men who had no proved qualification for their duties, but who would have the power of imposing heavy penalties on their fellow citizens.

Mr. Betty said this was a most important question. It was a known fact that gentlemen had come to that establishment to take a short course in the laboratory, in order to become public analysts, and had afterwards obtained appointments, and yet tradesmen were to have their reputation and purse placed at the mercy of men so qualified. How could it be said in the face of such facts that some guarantee was not required. He would also mention that as a ratepayer he had had to pay his share of the expense incurred through the blunders of a public analyst.

After some further discussion, in the course of which Mr. Sandford said he had taken a note of various points which had been mentioned for the purpose of laying them before the Government, and would also include the suggestion about the qualification of analysts,

Mr. Hampson consented to withdraw the latter part of the resolution, and it was then passed as follows unanimously:—

"That the Parliamentary Committee be requested to watch the progress of the Sale of Food and Drugs Bill, to prevent the introduction of objectionable clauses into the Bill."

The Preliminary Examination.

Mr. Atherton then moved the following resolution, of which he had given notice:—

"That the questions for the Preliminary examinations after the present year be prepared, and reported upon, by the College of Preceptors."

He did not wish in any way to depreciate the ability of the examiners or the fairness and honesty with which the examinations were conducted, but it was only fair and just to the Society that the Preliminary examinations in purely elementary scholastic subjects should be conducted by gentlemen who had received some special instruction in that direction. The question had been brought forward at the Pharmaceutical Conference at Brighton, by Mr. Atkins, who then proposed to do away with the Preliminary examinations altogether, and replace them by exacting a certificate from the College of Preceptors or Oxford and Cambridge Universities. The objection to that was, that the Society ought to have in its own hands the control of its own examinations. On that occasion Mr. Carteighe concurred in the desirability of these examinations being conducted by the College of Preceptors, and he had only to add that inquiries had been made whether that body would undertake the duties, and the reply was that they would be happy to do so, and that the fees would be about the same as those hitherto paid.

Mr. Greenish seconded the motion. He said he thought it would be admitted by every member of the Council that the Preliminary examination was, perhaps, the most important examination conducted by the Society. It was an inquiry whether the candidate had received a good early education, and to raise the status of the body it was necessary to commence with the Preliminary examination. That examinations were but imperfect tests of knowledge was admitted, and if the school education of this country were conducted on something like uniformity of plan, he would prefer as evidence of the candidate's education his having reached a certain "form," provided that "form" included classics, rather than the imperfect test of an examination. It was not intended that by the proposed change the system now in operation in regard to "centres" should be altered, but that for the present examination there should be substituted one conducted by a competent body, such as the College of Preceptors.

Mr. WILLIAMS doubted whether it was quite courteous to the Board of Examiners to pass such a resolution off hand without consulting them, and without an opportunity of considering the matter a little more. There were still eight or nine months before any step could be taken to carry it out, and he therefore suggested it should stand over for a time.

The PRESIDENT thought the course pursued a desirable one, but he doubted if this was the proper time to pass the resolution.

Mr. HAMPSON did not think there could be any offence given to the Board of Examiners, who, he should think, would rather feel it a relief than otherwise.

Mr. SCHACHT did not see any reason for making the proposed change, and thought they had better let well alone. He did not see the objections to the present system, or the advantages to be derived from that proposed. One thing was quite clear, that if they once parted with the control of these examinations they could never regain it or modify the examination. Practically, he believed there was no difficulty in the present system.

Mr. BAYNES was rather disposed to favour the view of Mr. Atherton, but he was hardly prepared to decide at that moment.

Mr. GREENISH said one of the examiners had expressed to him privately an opinion that it was the best course that could possibly be adopted.

Mr. RADLEY thought if this proposed change were to have the effect of making the examination more difficult it would be a great mistake.

Mr. SANDFORD thought the change could hardly be effected by a simple resolution.

After some furthur conversation the discussion was adjourned until next month.

CONVERSAZIONE.

Mr. WILLIAMS moved :—

"That a Conversazione be held on Wednesday the 19th of May next, and that the Secretary be instructed to apply to the Lords of Her Majesty's Council on Education, for permission to use the South Kensington Museum on the evening of that day, for such purpose."

He thought these meetings were very popular, and had been of some benefit in elevating the position and status of the trade before the medical and general public. At the same time, he must acknowledge the expenses had increased very considerably, and therefore, if they agreed to hold the Conversazione for the present year at South Kensington, the Committee should be instructed to curtail the expenditure as much as possible. He thought certain items might be reduced without interfering with the comfort of those attending. The number of admissions might also be somewhat limited. He had been informed that one member of the Society actually sent for as many as sixty tickets, and if this were the case it was certainly proper that some limit should be put.

Mr. OWEN seconded the motion.

Mr. HAMPSON said he had enjoyed the evenings at South Kensington extremely, but they were very expensive, and he did not really think the Council was justified in continuing such a large outlay.

After a discussion in which Mr. Robbins, Mr. Betty, and other members of the Council took part, the resolution was carried, and the President, Vice-President, and Treasurer, with Messrs. Sandford, Greenish, and Betty were appointed a Committee to make the necessary arrangements.

PHARMACEUTICAL MEETING.

Wednesday, March, 3, 1875.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting were read and confirmed. The following Donations to the Library and Museum were announced, and the thanks of the Society were awarded to the donors :—

To the Library :—Hooker's 'Flora of British India,' part 3, from the India Museum, per Dr. J. Forbes Watson; 'The Pathological Significance of Nematode Hæmatozoa,' by T. R. Lewis, M.B., and 'A Report of the Microscopical and Physiological Researches into the Agent or Agents producing Cholera,' second series, by T. R. Lewis, M.B., and D. D. Cunningham, M.B., from Mr. Lewis ; 'Year Book of Pharmacy, and Transactions of the British Pharmaceutical Conference, 1874,' one copy from the Conference, and one copy from Mr. Richard Bremridge ; 'Proceedings of the American Pharmaceutical Association, 1874,' from the Association ; 'The Analyst's Annual Note-Book, 1874,' from Mr. S. W. Rich ; 'Nouvelles Recherches sur les Liquides Pathologiques de la Cavité pleurale' (donor unknown).

To the Museum :—Specimens of Salicylic Acid, from Messrs. Domeier and Co. ; specimen of Crude Stearoptene of Japanese Oil of Peppermint, from Mr. Morson ; specimen of Jaborandi Root, from Messrs. Hopkin and Williams; specimens of Carnauba Root and of Fluid Extract made from it, India Rubber Milk, and Arariba, from Dr. Symes, of Liverpool.

To the Herbarium :—Fine specimens of the species of Cinchona, yielding the Java Barks, from Mr. J. E. Howard ; specimens of *Primula scotica*, Hook., *Lepidium Draba*, L., *Paris quadrifolia*, L., *Ornithopus perpusillus*, L., *Corydalis claviculata*, D.C., from Mr. G. C. Druce, of Northampton.

Professor BENTLEY called attention to the most valuable collection of Cinchonas which had been presented by Mr. Howard. The specimens were exceedingly interesting, and illustrated a paper which Mr. Howard contributed to the *Pharmaceutical Journal* in July, 1873, on the "Cinchona Plantations of Java." The cinchona in question was *Cinchona Calisaya* var. *Ledgeriana*, and was a particular variety of Calisaya yielding a bark of exceeding richness in alkaloid, far exceeding any of the barks which had been hitherto introduced from South America. The seeds from which this was obtained were collected by Mr. Ledger, who was well known as having introduced the alpaca from Peru into Australia. When the seeds came over, the Dutch consul asked him (Professor Bentley) for information about them, and he had advised the consul to obtain some of them. Mr. Howard also strongly advised their purchase. Some of the bark obtained from these plants had yielded 10 per cent. of alkaloid, which was a very extraordinary yield. It was very interesting and important that so large an amount should be got from cultivated plants. Special thanks were due to Mr. Howard for these valuable specimens. There was also on the table a specimen of Carnauba root which had been described by Dr. Symes in a recent number of the Journal. It had been imported into Liverpool, and was the root of a kind of palm, known as *Copernicia* or *Corypha cerifera*. It was stated to be valuable as an alterative, and to have exactly the same properties as sarsaparilla ; and Dr. Symes said that it could be obtained at half the price of sarsaparilla. He would also make an observation about a kind of chiretta, which he described in the *Pharmaceutical Journal* about three months ago. The interest connected with the subject was, that up to that time no spurious chiretta had ever been described by pharmacologists. He gave full particulars about it, and described a ready means by which spurious chiretta could be distinguished. The most distinguishing characters of the true chiretta were the marked continuous pith and the rounded form of the stems. The spurious chiretta had a distinctly angular stem, and only a trace of pith in the interior. There were other distinguishing characters for which he must refer to his paper. He had every reason to believe that a very large quantity of the spurious chiretta was likely to come into the English market, and, in fact, since his paper was written a great deal had been imported. The other day he had also received from Mr. Hanbury an extract from a letter on the subject, written to him by Dr. Dymock, Professor of Materia Medica, Bombay. The extract was as follows :—

"I saw a short time ago a notice in the *Pharmaceutical Journal* of some false chiretta. You are likely to get more of it, as it is very abundant in the market this year. It has been for a long time well known here as *Meetha Chirata*, or sweet chiretta. It comes in the same bales as the bitter kind, and is sorted out for sale here."

He (Professor Bentley) had very little doubt that the chiretta mentioned in the extract was the same kind as he had lately described, although at present he had no positive evidence on the subject. Professor Bentley said he should feel much obliged, in case anyone should meet with a spurious chiretta, if he would send him a good sample for examination.

Mr. Greenish said that Mr. Holmes had furnished him with a specimen of the spurious chiretta described by Professor Bentley; and upon comparing the section under the microscope with that of the true chiretta, he had found the differences which Professor Bentley had just described.

Professor Attfield said that there was on the table another specimen presented by Dr. Symes, of Liverpool. It appeared under the name of arariba, and it was described as a species of Cæsalpinia. The specimen was a portion of some arariba which had been recently offered for sale in Liverpool. The substance had been recently the subject of a research, the results of which would be read before the North British Branch of the Pharmaceutical Society at its next meeting.

Mr. Martindale asked whether any gentleman who was present could establish the identity of ariroba with Goa powder. He believed that arariba was used in Brazil to some extent for psoriasis and other skin diseases. He was told that Goa powder was exported from Brazil to Goa, thence to Bombay, and there used for the same purpose.

Professor Attfield said that he had examined both Goa powder and ariroba, and he could state that the two were entirely distinct.

A special vote of thanks was accorded to Mr. Howard for the specimens of cinchona.

Lead Plaster.

A paper on "Lead Plaster" was read by Mr. Charles Umney. It is printed at p. 701. and gave rise to the following discussion.

Mr. Haselden said that he had experimented but little upon the plumbic plaster of the British Pharmacopœia, and had found that it was sticky, and when spread took several days to dry in the autumn of the year. The plaster prepared from the London Pharmacopœia formula dried more rapidly, and, so far, would be more useful to persons who wished to spread plasters quickly. Plasters were not of so much importance to pharmacists as medicines used internally; but, still, if a better plaster could be obtained by using only half the quantity of litharge to that of oil, that *i.e.* 1 to 2, it was desirable that the alteration should be made. No doubt those who manufactured plasters to a large extent would use the form which they found most profitable and convenient for themselves, and best adapted for general use. The firmness and time of the adhesion of a plaster depended, to some extent, upon whether it was spread upon calico or linen. Surgeons in former days had complained that resin plaster for dressing wounds was not so good spread upon calico, and they always had a preference for plasters spread upon linen. If lead plaster entered into the composition of some cerates, very likely B. P. plaster would be more useful than the London Pharmacopœia plaster, inasmuch as it would keep soft longer, only it would get rancid a little sooner. An objectionable quality in all plasters containing lead, and in all ointments containing lead, was that, in spite of being made with benzoated lard, they after a time became rancid and offensive. The B. P. plaster made a very fair plaster when spread upon leather, if it had time to dry; and in cold weather after a time it became as dry as the London Pharmacopœia plaster.

Mr. Gerrard said that having prepared some hundredweights of lead plaster, and spread some thousands of yards, he was made acquainted with the deficiency in quality of the present British Pharmacopœia plaster when it first became official; and ever since that time he had prepared plaster very nearly according to the London Pharmacopœia, but adding a little more oil. The London Pharmacopœia plaster was a little too stiff and cracky. The extra quantity of oil rendered it pliable. The B.P. plaster was too sticky for adhesion when prepared in the summer months, although it appeared to be a very nice plaster at this time of the year, when the temperature ranged low. He had with him specimens of two plasters which he had that day prepared. One was the B. P. plaster, and the other was the plaster which he was now in the habit of making, and which contained a little more oil than the London Pharmacopœia plaster. The latter had been boiled, and had the whole of the water removed, but not quite all the glycerine. He would suggest to the wholesale trade that they should evaporate more than they were in the habit of doing. Perhaps, however, if they could get 10*d*. a pound for water, it was not very likely that they would evaporate to a greater extent than they did at present. If they remembered that it was the office of a plaster to adhere to, and support, the parts to which it was attached, they would at once come to the conclusion that it should be of a nature to maintain itself upon the parts upon which it was placed, and that was what the British Pharmacopœia plaster failed to do.

Mr. Martindale said that he had had but little experience in the making the lead plasters, but he had spread a considerable quantity. He could scarcely say that he could support Mr. Umney. In fact, he should be inclined to give the Scotch verdict, "not proven." From the formula of the British Pharmacopœia he had succeeded in getting the best plaster he had ever spread. Wholesale houses generally sent out the plaster not half finished, containing a large quantity of water, etc.; what was worse—nearly all the glycerine which it was capable of containing. In his opinion the glycerine, as well as the water, must all be removed. If a plaster spreader spread either of Mr. Umney's samples, he would find that after a fortnight they would be brittle, and if spread upon ordinary glazed cloth the adhesive portion would peel off rapidly. He believed that if a lead plaster was made pliable with a sufficient amount of olive oil, it was possible to keep it for several years. The adhesive plaster which he had spread for use at University College Hospital for several years was nothing more than lead plaster washed and boiled to such an extent that the whole of the water and glycerine were driven off. In that condition it was as transparent as amber resin. It would remain pliable for a month after being spread. He was sure that the samples exhibited by Mr. Umney would not remain a week in that state. Professor Redwood had stated correctly that this plaster resembled the kind used by the late Dr. Scott, which is still in request in some of the hospitals. It was a pure lead plaster He (Mr. Martindale) entirely disagreed with Mr. Umney that the London Pharmacopœia was better than the British Pharmacopœia plaster. The British plaster was not too "sticky" if properly finished, *i. e.*, freed from both glycerine and water. It was left unfinished to suit the convenience of the wholesale manufacturers for sending out in rolls to the trade; but that was quite a different thing from being such a plaster as would adhere when spread either upon cloth or calico. Linen used to be preferred for plasters, but he supposed that plaster spreaders found it more to their advantage to use calico. It was now the custom to use calico containing a large amount of glaze, so as to prevent the plaster from soaking through the fabric; but a plaster spread upon such a material was deficient in adhering properties when applied to the edges of a wound. Plaster spread upon an unglazed material had a much better grip on the edges of a wound, and would combine them for a much longer period. He would like to ask both Mr. Umney and Mr. Gerrard, and particularly Mr. Gerrard, whether their remarks applied to an adhesive lead plaster used as such, or to the resin plaster made from it. The addition of the resin made the plaster quite a different article. It was not desirable to have resin in an adhesive plaster, and in certain constitutions it would produce an amount of eczema round the margin of the wound.

Professor Redwood said that he could hardly too strongly express his sense of appreciation of the paper which had been read. The writer had gone into the subject in a business-like way, and carried out the investigation in the very best spirit. He should, however, have appreciated the value of the communication more if Mr. Umney had more explicitly described the nature of the oil which he used in the process. Mr. Umney could not be ignorant of the fact which had been observed by plaster makers, that the self-same process occasionally gave different results. He (Professor Redwood) had on several occasions been consulted by plaster makers on account of their lead plasters becoming sticky and unusable. Mr. Squire, in his 'Companion to the British Pharmacopœia,' stated that the British Pharmacopœia plaster answered only when it was made with the best Italian olive oil. If Gallipoli or Spanish oil was used, the process was not satisfactory. He should have felt better satisfied if Mr. Umney had extended his experiments by using oils of different qualities. This was a point upon which they might clearly look for a little further investigation, and that investigation could not be in better hands than Mr. Umney's. That gentleman had referred to an opinion which he (Professor Redwood) had expressed in that room. That opinion, however, was one of very little value, because it was not founded upon his own experience. But, at the same time he had been assured, by men upon whose judgment he could place implicit reliance, that the alteration in the process was an improvement in certain respects, and that it accomplished and realized that at which medical men and pharmacists had been for some time aiming. However, he certainly considered that the subject was a perfectly open one for discussion and investigation. But he must confess that he had been rather strengthened in the opinion which he had formed in favour of the British Pharmacopœia formula by his knowledge of the circumstances under which that formula was introduced. He did not hold himself responsible for the process, for it was introduced into the British Pharmacopœia in the year 1864, when he had nothing to do with it. But though not responsible for the process he had been mixed up with its introduction. It originated from a committee appointed by the Pharmaceutical Society, at the suggestion of the London College of Physicians, with a view to making alterations in the processes contained in the Pharmacopœia. He had the honour of acting as honorary secretary to the committee; and in connection with his office he made a great many experiments upon a large number of Pharmacopœia preparations; and associated with him as members of the committee were men of great practical skill and experience as pharmacists. Among them he might mention the late Mr. Henry Deane, Mr. Peter Squire, and Mr. Thomas Herring, all of whom took a deep interest in this very question of emplastrum plumbi. It was left to Mr. Deane to make inquiry as to the process which was adopted by a well known large manufacturer who had a high reputation for adhesive lead plaster, and whose plaster was considered to be the plaster which was originally introduced by Dr. Scott of Bromley. He (Professor Redwood) was not able to say absolutely that the formula as it now stood in the Pharmacopœia was exactly the same as that which was introduced to the committee in this way; but he was quite prepared to say that it was suggested to the committee that in order to produce a plaster which should be sufficiently adhesive and sufficiently firm to answer all the purposes of strapping it was necessary to employ the very best olive oil, and to diminish the proportion of oxide of lead which was at that time ordered. The points to which the committee was directed were the quality of the oil, the diminished proportion of the oxide of lead, and long continued boiling. The boiling was to be continued even beyond the time when there was evidence of combination having taken place between the ingredients. He was not prepared at once to concede that the committee had made a mistake. It paid much attention to the subject, and went thoroughly into it, and he could perfectly well remember Mr. Thomas Herring saying afterwards that a great improvement had been effected in lead plaster by the process which had been adopted by the committee. Looking back at the circumstances under which the alteration was proposed, he felt justified in adhering to his opinion until stronger evidence was produced than that which Mr. Umney had brought forward. He freely admitted that what Mr. Umney had done was exceedingly to the purpose, and very valuable, and he esteemed it very much; but he (Professor Redwood) wanted something more to induce him to say that he would give up the process of the British Pharmacopœia, and go back to that of the London Pharmacopœia.

Mr. Wells said that, having communicated a short article to the *Pharmaceutical Journal* in October, 1874, on emplastrum plumbi, he wished to say that he not only supported Mr. Umney's statement, but was prepared to go further than he did. Professor Redwood had, very properly, alluded to the quality of the oil; but his (Mr. Wells's) experience, which was, at one time, very extensive, convinced him that the oil occupied a secondary place and the litharge a primary one. He could never make a satisfactory plaster with bad litharge and good oil; but with good litharge he could make a splendid plaster, even with Gallipoli oil. He did not defend the process which they would find in the *Pharmaceutical Journal*; but he maintained that in order to get a plaster which would fulfil the intention of the person using it, they must use considerably more litharge than the quantity ordered in the old London Pharmacopœia. The proportions were 20 parts, by weight, of litharge, and 28 parts of oil. Much depended, as Professor Redwood had justly observed, upon the length of time occupied in boiling. Twelve hours were even better than ten. And much depended upon the entire evaporation of the water. If the plaster was allowed to solidify and stand all night, there was a very large proportion of what was now known to be glycerine, floating on the top. But that was not known as glycerine at the time to which he was alluding, namely—thirty-four or thirty-five years ago. Every particle of the glycerine was removed, and the plaster was heated up again. He must confess that he had never seen a plaster which served its purpose so well as plaster so prepared. It did not get decolorized, and after keeping it for years, he had found it to be as good as at first. He would suggest to Professor Redwood, knowing what an authority he was upon such matters, whether it would not be expedient to institute some fresh experiments, and even increase the quantity of litharge, taking care, of course, that that substance was really good and pure. By the addition of liquor potassæ at the end of the process, every particle of free oil in the plaster was completely saponified. He was not entering into a medical discussion of the subject, but he was simply speaking of a product which he had never seen surpassed.

Mr. Moss said that his experience of the manufacturing of emplastrum plumbi had been limited to the British Pharmacopœia formula; but he could say that, as far as his experience went, that formula gave an excellent result. He could not at all sympathize with Mr. Umney when he spoke so feelingly of the complaints and disappointments which followered the sending out of the British Pharmacopœia emplastrum plumbi. Nor did he agree with the other remarks which had been made against it. The house with which he was connected, sent it out all the year round.

Mr. Gerrard said that he had experimented with what he believed to be pure Italian oil, and the result which he obtained quite coincided with that stated by Mr. Umney, whether he boiled the preparation for a long period or a short period. There was a very sweet and efficient oil, called nut oil, which formed an excellent plaster, and was less prone to rancidity than olive oil. He agreed with Mr. Haselden that nothing was better suited than linen as a material upon which to spread plasters. It was more free from "dress," and from the glaze of the surface which was found in ordinary diachylon plaster. Linen was also more absorbent than other materials, and this quality caused the plaster to adhere to it better. Instead of the plaster peeling off, the linen stuck to the plaster, and the plaster stuck to the patient. He quite agreed that the addition of resin to a plaster improved it, but he could not speak with reference to the potash. In all plasters which he prepared for surgeons' use he added a portion of soap and common resin; and his experience during ten years in Guy's Hospital was that surgeons held the plasters to be useless without those additions. He had introduced the same preparation in University College Hospital, and the consumption had increased 50 per cent.

Mr. Umney, in reply, said that Mr. Haselden had mentioned the use of emplastrum plumbi, B.P., when entering into the composition of a cerate. He had sent some of that plaster to a noted house to be used for the preparation of neutral cerate, which was a favourite remedy of the late Sir Benjamin Brodie, and it had been found that instead of making a neutral, it made an acid cerate. He therefore maintained that they could not use this plaster for unguentum plumbi comp. of the London Pharmacopœia, as the compound would be acid. To Mr. Gerrard's remarks he must take only one exception, and that related to the quantity of water which he imagined wholesale druggists were anxious to leave in the plaster. When he (Mr. Umney) took 100lbs. of oil and 53·8lbs. of litharge, the plaster which he produced weighed only about 156 or 157lbs., showing that there was not much desire to leave water in the preparation. With regard to Mr. Martindale's statement as to the cracking of the P.L. plaster, he (Mr. Umney) spread some of it some six months since, and up to the present time it had not cracked. It had been spread by a machine upon calico. Mr. Martindale had alluded to the admixture of resin, but the paper had not dealt with that subject. As to the quantity of water stated to be in the plaster of trade, it would be evident that if a pan was subjected to heat produced by a pressure of from one to one and a-half atmospheres of steam (temperature about 240°) for six hours, there could not be much water in the compound. The glycerine was left almost wholly in the plaster, but to go into that question would be beside the discussion. He could quite corroborate Mr. Martindale's statement that the plaster of the Pharmacopœia could be much improved; but they were dealing with the formula as it stood, and the question was whether the process was a practical one. It had been said that an ounce of practice was worth a ton of theory; and this matter was essentially a practical one. Professor Redwood had said that he should want stronger evidence before he became convinced that the British Pharmacopœia formula was not a good one. He (Mr. Umney) held in his hand some dozen letters which he should be very glad to hand to Professor Redwood after the meeting. They would give the finishing stroke to Professor Redwood's opinion on the subject, certainly as far as spread plaster was concerned. He quite agreed that it was possible to send out British Pharmacopœia plaster rolled, but not spread. Possibly Mr. Moss's experience was confined to rolled plaster. He (Mr. Umney) had had the British Pharmacopœia plaster returned to him when he had sent it instead of the P.L. plaster which he had described in the paper. As to the question of oil, he had been most particular to use the very finest olive oil which could be obtained in the city of London for his experiments. He was astounded to hear Professor Redwood adduce the opinion of the late Mr. T. Herring as to the superiority of the B. P. plaster, for the laboratory journals of Herrings and Co., as far as he (Mr. Umney) had found, contained no entry of plaster by this B. P. formula until he made it in their laboratory in 1864. He regarded the evidence of the plaster spreaders against the B. P. plaster as stronger than that of the wholesale druggists.

The President expressed the thanks of the meeting to Mr. Umney, and remarked that there was room for further experiment on the subject. Perhaps Professor Redwood would take up Mr. Wells's suggestion as to the quality of the litharge.

The Estimation of Fat in Milk.

A paper on "The Estimation of Fat in Milk" was read by Mr. E. L. Cleaver. The paper is printed at p. 702, and gave rise to the following discussion:—

The author remarked that he had been led to write this paper by the fact that in some recent analyses of milk by London analysts the fat was the point upon which they had differed. A magistrate had remarked that if analysts could differ so much, the analysis of milk was not to be depended on.

Mr. Urwick said that he had found Mr. Horsley's plan to answer very well. Invariably the number of lines read off corresponded to the fat in the proportion stated. He had never seen any remarks upon the differences of quality between specimens of milk taken from different depths in the can after the milk had been standing for an hour or two. He had found that milk at the top of the can had yielded even as much as 25 per cent. of cream, while that at the lower part would fall as low as 9 per cent.

Professor Attfield said the excessive amount of fat found in the upper portions of the milk had been referred to in some investigations which were made sufficiently long ago to be embodied in at least one book. It would be, of course, naturally expected that the cream would rise to the top of the can. He could confirm what Mr. Cleaver had said about the difficulty of extracting the fat from a milk residue. He could partially confirm what he stated respecting the loss of fat through the ebullition of the ether. But he could not altogether confirm what he stated about the loss of material by decrepitation during the evaporation of the ether. He should like Mr. Cleaver to explain whether he relied upon the volumetric method or upon the gravimetric method in estimating the fat of milk. In the early part of his paper he threw some doubt upon the volumetric method; and then in the latter part he stated that the gravimetric method as improved by himself produced nearly all the results obtained by the volumetric method.

Mr. Cleaver, in answer, said that most of his experiments had been made comparatively. He had analysed a sample both by Mr. Horsley's method and by the gravimetric method; but by his own process, he had never been able to get as much fat as Mr. Horsley's method showed. He therefore concluded that, either the fat was not all dissolved out, or else that the volume was too great. Mr Ekin, however, had stated at the British Pharmaceutical Conference that he could always get the right amount.

Professor REDWOOD said that he could not agree with Mr. Cleaver in all points, but it was nevertheless very interesting to hear the results which were obtained by different operators. As far as his experience went there was no kind of analysis in which public analysts agreed so nearly in their results as in the analysis of milk. Nearly all public analysts now adopted one common method, which was very nearly that which had been indicated in the paper. The process known as Mr. Horsley's method—which had been adopted many years before in France—was adopted by very few analysts. The process generally used was essentially that which Wanklyn had described and adopted.

Mr. CLEAVER said that Professor Redwood stated at a recent meeting of public analysts that he adopted the second process which was described in the paper. That was not the same as Mr. Wanklyn's method. If he had given up that process, was it because it did not answer?

Professor REDWOOD said that the process was the same as Mr. Wanklyn's in principle, but a little different in the mode of separating the fatty matter. Mr. Wanklyn recommended a certain amount of milk to be evaporatsd to dryness in a platinum dish. The solid residue adhered to the dish and formed a solid cake. He then added ether, and boiled the ether in it. Then he turned the mixture into a filter, and evaporated away the ether, and estimated the fat that was left. That was Mr. Wanklyn's mode. He (Professor Redwood) did not adopt it in all its details. Instead of using a platinum dish he preferred a hemispherical German porcelain dish, because he could easily separate everything which adhered to such dish; and by careful manipulation towards the latter part of the process the whole of the solid residue was brought into a perfectly fine granular condition. Every dish had its weight marked on the outside, and that weight did not vary to the extent of one-hundredth of a grain, even after five or six months' daily use, if the dish was perfectly glazed inside and out. The residue was next exhausted with ether, the ether being added in three or four successive portions. Upon the ether being added, the dish was placed upon the water-bath, but they carefully avoided boiling it, for the reason to which Mr. Cleaver had alluded, which was that the liquid was apt to spirt, and thus cause a loss. Each dish was furnished with a little glass rod, which was rounded at each end, and the whole contents of the dish were stirred together. The rod served to break down any of the larger particles of the granulated solid residue. This residue subsided with very great facility and very quickly, so that the ether was generally left transparent. This was decanted into a beaker, so that there was the means of observing whether any solid matter was decanted away or not. This treatment with the ether took place four times. The liquid never went into a filter, and the solid residue from which the result was estimated never went out of the dish. An entry was made in a book of the contents of each dish; for he might state that he sometimes had perhaps twelve or fifteen or twenty samples of milk to analyse in a day, and therefore it was necessary to be extremely careful that there was no confusion of one sample with another. Each sample was marked by a number and a letter, and that was entered in the book, and the weight of the dish was put against the entry. Each dish had a special weight, no two dishes agreeing in that respect; and hence there was no chance of one dish being mistaken for another, or of an admixture of the samples during the process of analysis. The fat was dissolved out with the ether and simply decanted off. When he was satisfied that no solid matter had been carried away with the fat, it went into a common bottle, and the ether was distilled away when a quantity had been accumulated so that it might be used over again. When the first solid residue had been evaporated to dryness, so that it lost no more weight, its weight was entered against the weight of the dish. After it had been exhausted with the ether and the fat had been taken away, the weight of the non-fatty solid residue was entered again, and the one weight deducted from the other, the difference of weight representing the fat which had been dissolved out. All these results were obtained in the dish, and the sample never went out of the dish. No other apparatus was employed in the process. The material never went into the filter. The specific gravity of the milk was taken before the process was commenced, and if there was any doubt as to the milk being genuine, there were two other operations which would be performed, in which case, certainly, the residue had to be turned out of the dish. If there was any doubt about it, the ash was determined, and for the determination of that the non-fatty solid residue was turned into a platinum dish and calcined, and then its weight taken. Then the ash was treated with distilled water. That which the water dissolved out had the chlorine estimated. Those were the only determinations that were required or resorted to, and that, he believed, was the general mode of operating that was adopted by public analysts with very few exceptions.

Obituary.

We regret to have to announce the death, on the 20th of February, of Mr. John Palk, Pharmaceutical Chemist, of Exeter, one of the Founders of the Pharmaceutical Society, and a Life Member. Mr. Palk for many years carried on the business of a chemists' valuer, in which connection his name will be familiar to many of our readers. About two years since he retired from business. On the 20th ult. he was taken ill at Barnstaple, through which town he was passing whilst on a trip for change of air, and died three hours afterwards.

Another Founder and Life Member of the Pharmaceutical Society, has passed away in Mr. Charles Colin Luckombe, Pharmaceutical Chemist, of Radley Lodge, Wimbledon Common. In the early years of the Pharmaceutical Society, Mr. Luckombe took a great interest in its affairs and served it as an Auditor.

Notice has also been received of the death of the following:—

On January 4, 1875, Mr. Thomas Stephens, Pharmaceutical Chemist, of Merthyr Tydvil. Mr. Stephens had been a Member of the Pharmaceutical Society since 1853.

On January 11, 1875, Mr. John Dunn, Chemist and Druggist, of West Port, Selkirk.

On January 29, 1875, Mr. George Wilkes, Pharmaceutical Chemist, of Mile End Road, E. Mr. Wilkes had been a Member of the Pharmaceutical Society since 1842.

On January 31, 1875, Mr. John S. Schibild, Chemist and Druggist, of Willow Walk, S.E.

On February 3, 1875, Mr. Francis Toogood, Chemist and Druggist, of Caroline Street, Hull.

On February 11, 1875, Mr. Sylvester L'Amy, Chemist and Druggist, of Dundee.

On February 12, 1875, Mr. Stephen Langley, Chemist and Druggist, of Moor Street, Chepstow. Mr. Langley had been a Member of the Pharmaceutical Society since 1870.

On February 14, 1875, Mr. William Gordon Inglis, Chemist and Druggist, of James Street, Cardiff.

On February 15, 1875, Mr. James Wilshaw, Pharmaceutical Chemist, of Wordsley. Mr. Wilshaw had been a Member of the Pharmaceutical Society since 1853.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Year-Book of Pharmacy, comprising Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign Journals, from July 1, 1873, to June 30, 1874. With the Transactions of the British Pharmaceutical Conference at the Eleventh Annual Meeting held at London, August 1874. London: J. and A. Churchill. 1874.

Proceedings of the American Pharmaceutical Association at the Twenty-second Annual Meeting. Philadelphia. 1875.

A. A.—In the 'Additions to the British Pharmacopœia' it is recommended that Sapo Animalis should be used in preparing the Lin. Potassii Iodidi c. Sapone. When this is done the liniment forms an opaque white jelly.

C. Gerring.—Several articles on the *Eucalyptus globulus* have from time to time appeared in this Journal. See Professor Bentley's lecture in vol. iv., p. 872.

Ratæ.—April.

W. S. Hall.—The question is one that lies outside our department. You would probably obtain the information you require by application to the Secretary.

A. H. Finch.—The reference to a formula for Rubini's camphor is given quite correctly in the Year Book for 1871; viz., *Pharm. Journ.*, 3rd series, vol. i., p. 397.

W. Mount.—You cannot claim exemption on the ground of being a pharmaceutical chemist.

Percy Wells.—The Chemical Testing of Wines and Spirits by J. J. Griffin.

J. Young.—An Index to the 16th vol. of the first series of the *Pharm. Journ.* and the first eleven volumes of the second series has been published, copies of which, price 2*s.* 6*d.* each, may be obtained from the Secretary.

T. Appleton.—No binding cases are prepared.

We are compelled through want of room to defer the publication of several communications.

Communications, Letters, etc., have been received from Mr. E. Schiemann, Mr. P. Wells, Mr. J. Armstrong, Mr. E. Davies, Mr. Symes, Mr. Schorlemmer, Mr. Laird, Mr. Cope, Mr. Cocking, "Fideliter peragimus artem," "Vicar," "Semper Eadem," J. G. C., J. T. C.

A RESEARCH ON "CHRYSAROBINE."*

ARAROBA POWDER.—BAHIA POWDER.—GOA POWDER.†

BY PROFESSOR ATTFIELD,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain.

1. The "chrysarobine" with which this research was made was a yellow powder containing some fragments of vegetable fibre. It was sent to the writer by Mr. David Kemp, F.C.S., Bombay.

On drying at 100° C., and then burning, it yielded:—

Moisture	1·17 per cent.
Combustible Matter	98·40 "
Mineral Matter (Ash) . . .	0·43 "
	100·00

2. The ash was composed mainly of silicate of aluminium and the sulphates of potassium and sodium.

3. During the combustion for ash much yellow vapours or fumes were noticed; they were readily condensed on any cold surface.

4. Some of the "chrysarobine" was placed on a watch-glass over the smallest gas-jets of an argand-burner, and another watch-glass inverted over the first. After twelve hours the powder had lost one-tenth in weight, a very small quantity of sublimate occurring on the upper watch-glass. On raising the temperature, fumes were evolved, more sublimate obtained, and a charred residue remained.

5. Under the microscope the sublimate from the chrysarobine appeared moss-like rather than crystalline. Acids scarcely affected it; alkalies coloured it red.

6. Treatment of the chrysarobine with cold water yielded no satisfactory results.

7. Treatment of chrysarobine with hot water resulted in the ready removal of about 7 per cent. of matter; continued treatment with hot water gave a very weak solution: suggesting the idea of the presence of some substance easily dissolved by hot water, and of a substance in much larger amount and only slightly soluble in hot water.

* Read at a Meeting of the North British Branch of the Pharmaceutical Society of Great Britain, on Friday, March 5, 1875.

† *Note.*—March 10, 1875. According to Dr. J. F. Da Silva Lima, of Brazil (*Medical Times and Gazette*, March 6, 1875, reprinted at the end of this article) araroba or arariba is the name of a leguminous tree, having yellow pith. Dr. Lima, Dr. J. L. Paterson, who recently visited Bahia, and Dr. J. Fayrer, of Calcutta (*Medical Times and Gazette*, October 24, 1874), state that this yellow powder from the araroba tree has for many years been largely and successfully used for the external treatment of ringworm and other cutaneous diseases. Mr. D. S. Kemp, of Bombay, in the *Pharmaceutical Journal*, for February, 1864, described the same or an allied powder, which had long been imported through Goa, and hence termed Goa powder. Goa, it is true, seems to have produced a powder not always identical with araroba powder. One that I examined was certainly quite distinct. I am now inclined to think, however, that *true* Goa powder is identical with yellow araroba powder, though by age and the action of atmospheric ammonia it is liable to become of a reddish brown colour. Mr. Kemp's name of "Chrysarobine," literally yellow araroba, is clearly more appropriate than the synonymous Bahia powder, Goa powder, Brazil powder, ringworm powder, or even than powder of arariba or araroba, two names which according to Dr. Bomfim are used by South American Indians to indicate any "tawny-coloured" trees.—J. A.

8. The treatment with hot water was conducted in a retort with a condensing arrangement attached. The distillate was thoroughly examined, and the absence of any important amount of any kind of volatile matter in chrysarobine thereby proved.

9. The hot aqueous decoction of chrysarobine had a yellow colour and a bitter taste, was neutral to test-paper, scarcely affected by alcohol, gave no blue colour with iodine nor much red colour with potash, nor black with ferric chloride, though with ferrous sulphate and sulphuric acid it gave the black colour indicative of the presence of nitrates, and it readily reduced Fehling's copper solution.

10. Before examining the more important bulk of the chrysarobine, namely, the 90 per cent. of vegetable matter insoluble in water, the part soluble in hot water (about 7 per cent.) was subjected to investigation.

I. *Aqueous Extract of Chrysarobine.*

11. The chrysarobine was treated with hot water till the decoction ceased to taste bitter. This decoction was concentrated by evaporation. On cooling, some flocks separated which, when collected, slightly washed with cold water and examined, gave reactions similar to those afforded by the substance which sublimed when the chrysarobine was heated. Here it may be stated that the prolonged treatment of chrysarobine with hot water (after the 7 per cent. readily soluble matter is extracted) brings out only small quantities of the substance resembling the sublimate just mentioned. Postponing the examination of the sublimate and the flocks, the investigation of the 7 per cent. of readily soluble matter of chrysarobine was continued.

12. The filtered decoction was therefore precipitated by solution of acetate of lead, the filtrate from this precipitate treated with solution of sub-acetate of lead, and the filtrate from the resulting precipitate treated with sulphuretted hydrogen to remove lead, and then concentrated. Examination was then made of (*a*) the lead-acetate precipitate, (*b*) the lead-sub-acetate precipitate, and (*c*) that portion of the chrysarobine decoction not affected by acetate or by sub-acetate of lead.

13. *The lead-acetate precipitate.*—It had a reddish colour. It was washed with spirit of wine and treated with acetic acid, in which it nearly all dissolved. What little remained undissolved was found to be sulphate of lead. The acetic solution of the precipitate was saturated with sulphuretted hydrogen to remove lead, the lead sulphide separated by filtration, and the filtrate examined for chlorides, phosphates, citrates, and tartrates. Neither was present. The remaining portion was then evaporated to dryness. The red glass-like or resin-like residue was soluble in spirit, also in alkaline solutions, which yielded a precipitate when neutralized by acids.

The aqueous solution of the red body was not, apparently, very stable when subjected to prolonged evaporation. This liquid did not reduce Fehling's copper solution until after ebullition with diluted sulphuric acid, when it reduced the copper liquid readily. Of the substances present in the aqueous decoction of chrysarobine, that precipitated by lead-acetate has most of the characters of a glucoside.

14. *The lead-sub-acetate precipitate.*—It had a yellowish colour. It was separated, washed, and dissolved in acetic acid. Here also a little sulphate of lead was met with, probably protected from the

previous action of the lead-acetate by organic matter. The acetic solution contained neither chlorides, phosphates, tartrates, nor citrates. Evaporated to dryness, it afforded a residue nearly all soluble in alcohol. This constituent of chrysarobine, that is, the constituent readily removed by water, not precipitated by acetate of lead, but precipitated by subacetate of lead, is the bitter principle of chrysarobine. It is soluble in alcohol. Ether dissolved it in part. Both parts were bitter.

15. *The soluble constituent of chrysarobine decoction precipitable neither by lead-acetate nor lead-sub-acetate.*—After removal of the lead by sulphuretted hydrogen, the fluid was evaporated to a low bulk. A mass of acetates of potassium and sodium, with some nitrates crystallized out, the source of the acetic constituent being, of course, the lead-acetates, while the nitrates and the alkali metals came from the chrysarobine. The non-crystalline portion reduced Fehling's copper solution, but was not sweet to the taste.

II. *Benzolic Extract of Chrysarobine.*

16. The 90 per cent. of chrysarobine, insoluble, or almost insoluble in water, was dried and treated with benzole. About 84 of the 90 per cent. dissolved. The solution was yellow when dilute, and a deep brown when strong. On cooling a yellow granular substance separated in abundance. This substance gave all the reactions afforded by the sublimate of chrysarobine mentioned in sections 3 and 4. In alcohol it was less soluble than in benzole, still less in ether, and very slightly soluble in water. These solvents affected it more rapidly and powerfully when hot than when cold; and hot solutions deposited it on cooling. It was soluble in aqueous solution of potash, with formation of a deep red solution. Acids re-precipitated it from such alkaline solutions. If the alkaline solutions were exposed to air, some alterations went on, and the acids then gave a brown instead of a yellow precipitate. In an alcoholic solution of potash this alteration was not observed. The most minute trace of the substance gave the red coloration with potash. Heat affected it in the manner that heat affected the chrysarobine. On the addition of the solution of alum to the potash solution, a copious light brown precipitate resulted. The substance dissolved slightly in solution of ammonia, and the resulting pink solution gave a pink precipitate on the addition of alum solution, and a lilac coloured precipitate on the addition of acetate of lead. Water added to the alcoholic solution of the substance caused partial precipitation. By re-crystallization from benzole it was sometimes obtained in crystalline tufts.

17. The yellow substance (obtained on washing chrysarobine with hot water, drying it, treating the dried and now purified chrysarobine with boiling benzole, cooling the benzole and then twice re-crystallizing from alcohol the yellow substance deposited from the hot benzole) was burnt to ascertain its percentage of carbon, hydrogen, and (by difference) oxygen.

18. The same yellow body re-crystallized from ether was also burnt.

19. The similar yellow substance obtained from the washed and dried chrysarobine by alcoholic potash (in an atmosphere of hydrogen to prevent oxidation), precipitation by dilute acid and re-crystallization from hot alcohol was also burnt.

The three combustions yielded the following results:—

(17.) Yellow substance extracted by benzole and alcohol—

Carbon	75 93
Hydrogen	7·70
Oxygen	16·37
	100·00

This substance crystallized several more times from alcohol was thus purified from a resinous body — probably a hydrocarbon — and was again burnt.

(17*a.*) Yellow substance extracted by benzole and alcohol—

Carbon	72·73
Hydrogen	5·23
Oxygen	22·04
	100·00

(18 and 19.) These, corrected for moisture afterwards found to be present, yielded—

	(18)	(19)
Carbon	69·3	69·3
Hydrogen	4·6	4·3

20. The figures just given, and all the reactions already mentioned, clearly indicate that the chief constituent of chrysarobine is CHRYSOPHANIC ACID.

21. Chrysophanic acid is so called from the Greek "gold-shining" or "yellow-shining."

22. The word chrysarobine has doubtless been given in allusion to the yellow colour of this arobine or arariba. In Martius's 'Systema Materiæ Medicæ Vegetabilis Brasiliensis,' page 125, heading Leguminosæ, subheading Cæsalpineæ, I find an allusion to "other leguminous trees," including "arariba." The name chrysarobine could scarcely have been more happily chosen had the facts of this research been known before hand. Mr. Holmes, Curator of the Museum of the Pharmaceutical Society, tells me that there is in the Museum some crude Arariba from Bahia which resembles chrysarobine but contains fragments of wood, the crevices and interstices of which are filled by a powder resembling the chrysarobine itself.

This confirms a statement made by Mr. Kemp, of Bombay, in a letter to the writer, that chrysarobine is the "pith" of a tree. (See also the footnote to the former part of this paper.)

23. Chrysarobine yields—in addition to 1 per cent. of moisture, 7 per cent. of a glucoside, a bitter and a gummy matter, and over 80 per cent. of chrysophanic acid—about 10 per cent of material insoluble in water or benzole. This residual material, when dried, was digested in hot strong alcohol. The alcoholic liquid evaporated gave a reddish-yellow resin-like body from which ether extracted (and re-deposited on evaporation) a yellow resin-like substance, leaving a red resin-like matter insoluble in ether. The final residue of chrysarobine, insoluble in hot water, hot benzole, or hot alcohol, was found to be woody fibre of a red colour. Exposed portions of the cæsalpinia wood before mentioned were noticed to be red.

24. Table showing at a glance the composition of chrysarobine :—

Name of Constituent.	Amount in 100 parts.
1 Moisture	about 1
13 Glucoside	}
14 A Bitter Principle or Principles	} „ 7
15 A variety of Arabin ?	}
16 to 20 Chrysophanic Acid	„ 80 to 84
23 Resin-like Bodies	2
23 Woody Fibre	$5\frac{1}{2}$
2 Mineral Matter (Ash)	$\frac{1}{2}$
	100

25. The glucoside and the bitter principle of chrysarobine deserve further investigation. To one or both may belong a portion of any medicinal activity possessed by chrysarobine when administered internally. In point of quantity chrysophanic acid is the chief constituent of chrysarobine. Four-fifths of chrysarobine is chrysophanic acid.

General Remarks.

Chrysophanic acid, obtained by sublimation, occurs in delicate golden-yellow shining scales or short needles. From solution it is deposited in minute silky crystals, or rather moss-like crystalline groups. Occasionally it crystallizes in minute "orange-yellow six-sided plates belonging to the oblique prismatic system."

Technology of Chrysarobine.—Chrysarobine may obviously be used as a yellow or orange-yellow dye. It would probably be best so employed as a weak alkaline bath. According to Grothe chrysophanic acid may be used with tin mordants for dyeing silk, wool, and linen; and with alum for dyeing cotton.

Therapeutics of Chrysarobine.—It is possible that the glucoside or the bitter principle of chrysarobine may possess medicinal activity. This point would best be decided by direct experiment, or at all events by experiments with the aqueous infusion of chrysarobine. Chrysophanic acid, according to Schroff, "exerts a purgative action . . . weaker than that of rhubarb." Rhubarb, it should be stated, contains a considerable quantity of chrysophanic acid, and this acid, with some resins and a bitter principle, are considered to be the conjoint source of the therapeutic properties of rhubarb. Chrysarobine may possibly be destined to be a rival of rhubarb as well as an external remedy for ringworm.

Pharmacy of Chrysarobine.—The proper mode of administering chrysarobine internally cannot be conclusively decided until the therapeutic characters of its aqueous extract be ascertained. So far as its chrysophanic acid is concerned, aqueous or alcoholic preparations would scarcely be admissible; a confection, the powder itself, or pills combined with soap, would be more appropriate. For external application in cases of ringworm and other cutaneous diseases Dr. Da Silva Lima recommends a pomade formed by mixing twenty grains of the powder and ten drops of acetic acid with an ounce of benzoated lard; to be applied to the roots of the hair at the part affected, by a camel-hair pencil. Dr. Fayrer uses a thin paste formed of the chrysarobine with vinegar or lemon-juice; this is painted over the eruption and for a little distance beyond its margin on to the sound skin.

To the scientific chemist chrysarobine may be commended as a new and rich source of chrysophanic acid.

As the substance which is the subject of the foregoing research is exciting considerable attention at the present moment, we append the following article which appeared in the *Medical Times and Gazette* for March 6:—

GOA POWDER.

BY J. F. DA SILVA LIMA, M.D.

(*Translated and annotated by J. L. Paterson, M.D.*)

I have read with much interest a paper in the *Medical Times and Gazette* of October 24, by Dr. Fayrer, of Calcutta, on the treatment of Indian ringworm by Goa powder. In this valuable communication—one of many such that have justly made him an authority on subjects of tropical pathology—Dr. Fayrer makes especial mention of certain cutaneous diseases—herpes circinatus, chloasma, and intertrigo—equally common here in Brazil as in India. In reference to the treatment of these eruptions, Dr. Fayrer states that he has found no remedy so rapidly or so certainly effective as the solution in vinegar or lime-juice of a secret preparation, which he believes of vegetable origin, sold in small phials by the chemists of Calcutta and Bombay under the name of Goa powder. Dr. Fayrer speaks of another powder very similar to the former, and equally efficacious in the treatment of the same diseases, known as "Poh di Bahia"—a designation which the author believes may be of Malay derivation. Mr. D. S. Kemp, Dr. Fayrer adds, from the fact of orchella (*Lichen orcella*) being imported in large quantities from the coast of Africa, north of Mozambique, into India, considers that substance as the probable source of the Goa powder. Mr. Hanbury, F.R.S., he says, on the contrary, alleges the Goa powder to be a secret remedy, whose composition and place of manufacture are alike unknown. It is with the view of calling attention to the employment in certain cutaneous diseases of this secret, and, as he believes, native remedy, that Dr. Fayrer at considerable length lays before the profession the results of his valuable experience.

Without pretending to unravel completely the mystery that has, doubtless for interested commercial purposes, been thrown around the nature, origin, and composition of the remedy or remedies so favourably spoken of by Dr. Fayrer, I am yet, I believe, in a position to furnish him and other medical men in India with such information as will lead to the establishment of the identity of the Goa powder and the Poh di Bahia with a popular remedy for many years employed in this and in other provinces of the Brazilian empire for the cure of various cutaneous affections, and more especially of herpes circinatus, chloasma, and intertrigo. The remedy I speak of is known in the province of Bahia under the name of Araroba powder, and in the other provinces of the empire, importing it as they do from Bahia, under that of Bahia powder (*po' de Bahia*.

Araroba, or, as some call it, Arariba, is the name of a tree belonging to the *Leguminosæ*, related perhaps to the tree of the same family furnishing the "Brazil wood" of commerce; several species of the Araroba, like Brazil wood, being employed as a dye. Araroba occurs in commerce either in the form of a rough powder or in small pieces of different sizes of a light yellow colour, becoming much darker on exposure to light and moisture. The part employed is said to be the medulla of the stem and branches. Reduced to a fine powder, it is in this country employed mixed with vinegar, just as the Goa powder and the Poh di Bahia in India, and produces exactly the same effects as, according to Dr. Fayrer, are produced by these—irritating and discolouring the skin, and producing more or less heat in the part, according to the strength employed. In the same manner, the dark colour left by its application disappears after a few days, as Dr. Fayrer says occurs after the application of the Indian remedies.

I may mention in passing that the irritating effects of the Araroba on the skin and mucous membranes are such that the manipulation of it is attended with much inconvenience. The workmen employed in cutting up and pounding it are obliged to cover up very carefully their heads in order to protect their face, eyes, mouth, nostrils, and throat against its irritating effects.

The efficacy of Araroba for the cure of certain cutaneous diseases is here well known—a thing neither questioned nor questionable; and I have myself had innumerable opportunities of verifying it in the case of the diseases cited by Dr. Fayrer, as also lately in a very obstinate case of mentagra that, having proved intractable to every variety of treatment, external and internal, yielded completely in a very short time to the application twice a day, by means of a camel-hair pencil, to the roots of the affected hairs of a pomade of Araroba, consisting of twenty grains of the Araroba powder, ten drops of acetic acid, and an ounce of the unguentum benzoini. Long before reading Dr. Fayrer's paper I had already suspected that the remedy which I had heard was in some parts of India used so advantageously for the treatment of herpes circinatus, and which was sold at a high price in the shops of Saigon and Singapore as the Poh Baia, was none other than our Araroba, more or less adulterated, perhaps, with other colouring matters. My chief reason for coming to this conclusion arose from my having had the good fortune in 1872 to make the acquaintance of Dr. Palasne de Champeaux, chief surgeon on board the French war steamer *La Place*, during that vessel's visit to our port. Our conversation naturally turned on the more specially tropical diseases, and among other interesting communications he informed me that in Saigon, having on board many cases of herpes circinatus intractable to the usually employed remedies, he had been induced to try a native remedy much vaunted in such cases under the name of Poh Baia, procurable only in small quantities and at an exorbitant price (two francs a gramme). He had employed it as there recommended, mixed with vinegar, and with marvellously good result. Telling him in reply that in Brazil the popular remedy for the cure of such cutaneous affections was the Araroba powder, known in the other provinces of the empire as the Po' de Bahia, mixed also with vinegar, the coincidence alike of the name, mode of application, and favourable results struck us both as suggesting the identity of the two remedies. On his leaving for Europe, I gave Dr. Champeaux some of the Araroba powder to take with him, and he afterwards employed it with exactly the same, only somewhat stronger, physiological and therapeutical effects as he had seen follow the use of the Poh Baia. These experiments and the conclusions come to by this distinguished member of our profession may be read, and will well repay the trouble, in the May number of the *Archives de Médicine Navale* for 1873.

I would add the following reflections, going far, I believe, to prove the identity of the Araroba powder with the Goa powder, the Poh di Bahia, and the Poh Baia:—

1. For a good many years back an old and well-known firm in this place has been in the habit of executing orders for large quantities of Araroba for Portugal.

2. Araroba (at all events, under that name), so far as I am aware, is unknown alike to the chemists and the medical men of Portugal.

3. It is therefore highly probable that the Araroba is from Portugal re-exported to its colonies on the coasts of Asia and Africa.

4. This probability will appear all the more when we learn from Dr. Fayrer, on the authority of Mr. Kemp, that from the north of Mozambique, a Portuguese settlement, there is exported for India a large quantity of urzella (*Lichen orcellis*); leading him to the inference of its being the chief constituent of the Goa powder.

5. Goa, importing Araroba from Lisbon, would have given its own name to the product over the rest of India, just as Bahia has given it its name in other parts of the Brazilian empire.

6. Thus the terms Goa powder and Po' de Bahia (the *poh di Bahia* of Dr. Fayrer, the *poh Baia* of Dr. Champeaux) would designate, all of them, the same original substance, more or less altered, it may be, by adulteration in India; the name Poh di Bahia coming from the name of the Brazilian province of which it is a native, and not, as Dr. Fayrer supposes, from any Malay origin.

7. Mr. Kemp's idea that the urzella is a chief constituent of the Goa powder may arise from the circumstance of their colouring, the one and the other alike, any object, such as the skin or clothes brought in contact with them.

8. As the perfect similarity of the *modus operandi* of all three remedies would seem to point to their intrinsic identity, so would their unvarying mode of application for therapeutical purposes appear to point to a common centre whence their use had sprung.

If the preceding considerations do not fully prove the identity of the three remedies, there can, at all events, be no doubt that the Araroba powder is as effective, or even more so, than either the Goa powder or the Poh di Bahia for the cure of those cutaneous affections for which these latter have been employed. Of this opinion is also Dr. Champeaux, who in the article already quoted says—"La poudre d'araroba est un ante-herpétique aussi puissant au moins que la poudre de poh Baia, si elle ne lui est identique." To corroborate still more the Brazilian origin of the remedy, Dr. Champeaux further remarks that on questioning the person who supplied the hospital at Saigon with medicines, he, with much equivocation, confessed nevertheless that the Poh Baia was not indigenous, but came from America.

As an appendix to Dr. Silva Lima's letter, Dr. Paterson writes, "I may state that from my own experience I can fully bear out all he asserts as to the beneficial effects of the Araroba powder in the treatment of the cases indicated in his paper. During a short visit which in the beginning of last year I paid to Bahia (I had formerly been twenty-five years in practice there), I learned from Dr. Bomfim, the distinguished professor of botany, that the names *araroba* and *arariba* are of Indian—that is, South American Indian—origin, and come from a stem signifying "tawny coloured," and that the name is by the native Indians applied to a great variety of trees, some of which are described by Martius in his 'Botany of Brazil,' none of these, however, at all corresponding with the plant from which the Araroba powder is procured; that this plant has not, as far as he is aware, been as yet described by any botanist; that he himself had had some of the leaves and the wood sent him, but had never seen a specimen of the tree, growing as it does in a distant part of the province. On my return in June I brought with me a small quantity of the powder, a portion of which I shall be very glad to give to anyone desirous of affording it a trial, which I am sure it will well repay; and in a few weeks any amount of it can be obtained, as in Brazil, if secret there be in the matter, it is the "open secret," whose only keepers are ignorance and indifference. I brought with me also, in default of the seed—the seed-bearing season having already passed,—two small Araroba plants from cuttings. These are now in the Royal Botanical Gardens of Edinburgh, for transmission to Dr. Little, of Singapore, who, during a short visit to Edinburgh a year or two ago, called on me, desirous to obtain some information in regard to the Po' de Bahia, which he, as well as other medical men in the East, had found by far the most effective remedy for the treatment of many cutaneous affections, and to ask me, if possible, to procure him some seeds of the plant producing it. He must therefore have discovered or surmised that the secret remedy sold as Po' de Bahia was of Brazilian origin. He was anxious to obtain some certain information in regard to the plant producing the powder, as one possibly, could they only know it, growing at their own door, and to free themselves at all events from the doubt, uncertainty, and humiliation attending the use of every quack medicine. If the Indian remedy is the Brazilian Araroba, how comes it that it is much better known to the profession (not the people) in India than in Brazil? This seeming paradox admits, perhaps of the following explanation.

Brazil up to the present time has no official pharmacopœia of its own, being content to use those of France and Portugal. Brazilian medical men, therefore, with scarcely one exception (Dr. Silva Lima is, however, one), after the failure probably of the more classical remedies, are content to tell their patients (or accept, perhaps, the suggestion of these) to give the Araroba a trial, referring them to the apothecary for instructions as to the mode of applying it—looking down rather on the untitled *parvenu* —for the *idolum tribus* grows as rankly in Brazil as in Europe. To the people it has from time immemorial been as much a household god as brimstone and treacle are to Englishmen—though you never see them in a prescription.

But again, how did the Araroba powder reach India? Up to 1822, when Brazil achieved its independence, all its intercourse with foreign countries, according to the policy of those times, took place through the mother-country. This gave rise to a regularly organized inter-colonial trade, now extinct, between the Brazilian and Asiatic colonies of Portugal. Hence, doubtless, the first introduction of the powder among the Portuguese residents of Goa, and its gradual spread over other parts of India; hence, too, the now roundabout mode of its transmission to India, and the consequent mystery there attending its origin—the chrysalis out of which the Brazilian grub emerges the butterfly of India.

The best mode of applying the remedy is, as Dr. Silva Lima recommends, in the form of ointment—twenty to forty grains of the powder with ten drops of acetic acid to an ounce of lard. As generally recommended it is much too irritating. I speak, of course, of the pure araroba powder.

ORTHOGRAPHY OF ASAFŒTIDA.*

BY ADOLPH W. MILLER, M.D., PH.D.

The duplication of a single letter may seem to many to be a very trivial matter indeed, though when philosophically considered, it is found to be quite worthy of attention and earnest consideration. As is well known, the majority of civilized nations use the Latin language in their prescriptions, and for the purpose of expressing many scientific terms pertaining to medicine. In order, therefore, to guard against ambiguity, it becomes an object of considerable importance to preserve the purity of this tongue. If every nation, or perchance every individual, were to adopt a peculiar orthography, the value of Latin as a common scientific language would be utterly destroyed; thus depriving both physicians and pharmacists of this convenient international medium of communication.

A diversity of the above kind seems to be at present prevailing in reference to the spelling of the Latin noun *asafœtida*—the *stercus diaboli* of modern nations, the *cibus deorum* of the ancients. A semblance of authority is given to the *ss* in the word by its adoption into the British and United States Pharmacopœias; on the other hand, the Pharmacopœa Germanica and almost all the most accurate authors write it with only a single *s*. As the Germans are generally regarded as being in advance of all other nations in profound philological knowledge, it is fair to presume that they have just and logical grounds for employing this form. In addition to this, the text-book of the German empire is invested with a much higher authority than ours, as it is issued under the immediate supervision and with the sanction of the general government.

If we may credit the accounts of Murray, the word asafœtida seems to have been introduced by the monks of the famous school of Salerno in the middle ages. It is not used by the Greek and Roman writers, so that it is searched for in vain in classical dictionaries. In order, therefore, to form an intelligent opinion on the subject, it becomes necessary to inquire into the derivation of the word, and also to note the preference shown by careful and competent writers for either of the two forms.

The term *asa* has been for ages applied to two different drugs, namely, *asa dulcis* (benzoin) and *asa fœtida*. The former seems to be used in Latin only with a single consonant, while the variation occurs in the latter. This apparent inconsistency is most probably to be accounted for by the name *asa dulcis* having become obsolete before the term *assa* came into vogue.

The origin of the word *asa* is veiled in so much obscurity, that different etymologists ascribe it to four entirely distinct sources. The first of these is the Latin word *laser* or *lasar*, which was applied to the juice of the plant *Laserpitium*. This was a medicine of great renown among the Romans, who knew it also as *Laser cyrenaicum*, or *Succus cyrenaicus*, and as *Silphium*. Many authors claim that laser was identical with asafœtida, though this is hardly probable, since Theophrastus, Aristophanes, and Dioscorides assign to it a sweet and agreeable flavour. Worcester, Muspratt, and many other writers mention this derivation. The word *laser* is itself derived by some authors quoted by Flückiger from the Greek σίλφιον as follows:—*silphi', sirphi', sirpe, lac serpitium, laserpitium.* The intermediate form *sirpe* is used by Plautus, B. C. 184. Francis Gouldman's 'Dictionary,' Cambridge, 1674, says:—*Laser est decurtatum ex Laserpitio. Laser herba cujus succus primum dict. Lactir, quoniam manet in modum lactis.* The same author then quaintly defines it as being "the loathsome liquor which issueth out of the stinking *laserpitium*, and is called of the apothecaries *Asa fœtida*."

The second derivation is from the triliteral root *asa*, occurring in several oriental languages; thus, *aza*, in Persian, means mastic, *isà*, in Arabic, a remedy, and *asa* signifies healing or curing in both Hebrew and Arabic, being often used substantively for a physician. Webster, Hager, Dorvault, the Paris Medical Dictionary, and others, favour this view. My esteemed friend, Dr. J. Thomas, a diligent student of comparative philology, and author of a medical and other dictionaries, has, at my request, investigated the subject. His conclusion is that the etymology from the Arabic *ăsâ* is altogether the most satisfactory, as the derivation from *laser* appears to him to be too far fetched. This gains additional plausibility from the well known fact that the school of Salerno obtained much of its erudition from the Arabic physicians. The writings of Rhazes and Avenrois enumerate asafœtida, and Avicenna mentions both the sweet and the stinking asa.

A third etymology is given by Flückiger in his '*Pharmakognosie des Pflanzenreiches*,' Berlin, 1867. He deems it probable that our *asa* and the Chinese *awei* both originated from the word *anguzeh*, or *ungoozeb*, as the dispensatory represents it, the modern Persian name of the plant furnishing the drug. It will be noted that all the roots so far enumerated contain only a single sibilant consonant.

The fourth and last source, which the writer has found only in Chambers's 'Encyclopædia,' is from a Persian word, *ăsā*, signifying staff. The chief motive for offering this seems to be that it is synonymous with the Greek νάρθηξ and the Latin *ferula*, both of which refer to the upright stalk of the plant. This is evidently a marked characteristic, as even its present name in the Aralo-Caspian territory is stinking reed (Keurök-Kurai). Chambers' 'Encyclopædia' spells assafœtida, and renders the above Persian word into English characters as *assa*. On the other hand, Chambers's 'Etymological Dictionary,' emanating from the same firm in 1869, edited by James Donald, only mentions assa, and refers to asafœtida. Furthermore, Duncan Forbes's 'Persian Grammar and Vocabulary' represents the word in English letters by *ăsā*. Again, Catafago's 'Arabic Dictionary' contains the same word, and renders it likewise as *asa*, with a peculiar guttural sound to the first vowel.

Although the authorities in English are divided on the orthography of asafœtida, it will be found that the majority favours the use of a single consonant, provided, of

* Read at a meeting of the Philadelphia College of Pharmacy (*Amer. Journ. Pharm.* for March).

course, that those are excluded who follow the pharmacopœias, simply because they are the accepted standard. Webster's 'Dictionary' merely enumerates assafœtida, and refers to asafœtida. Johnson's 'Dictionary,' by Dr. R. G. Latham, Sheridan's 'Dictionary,' and very many others give only the form *asa*. Dunglison's 'Medical Dictionary' gives asafœtida, and following it as a synonym assafœtida, in support of which the United States' Pharmacopœia is specially quoted. Gray's 'Supplement to the Pharmacopœia,' revised by Redwood, uses only asafœtida. The 'Pharmacographia' of Flückiger and Hanbury, which has just been published, also makes use of *asa*. This testimony is particularly valuable, since etymology seems to have received special attention from these authors, as shown by the recent discussion in the *Pharm. Journ.* on the spelling of *Chondodendron* or *Chondrodendron*. In opposition to this, Worcester prefers *assa*, but enumerates and defines also asafœtida, thus showing that he considers it nearly or quite as well authorized as the other form.

In German, the equivalent name *asant* is invariably written with the single *s*. In Spanish, Russian, and Portuguese, *asa* is used to the entire exclusion of *assa*.

The French dictionaries give *assa*, yet in opposition to this, Guibourt, in 'Histoire Naturelle des Drogues Simples,' and Dorvault, in 'l'Officine,' use *asa-fetida* only, and the 'Dictionnaire des Drogues,' by A. Chevallier and A. Richard, Paris, 1827, says:—"*Assa ou mieux asafœtida.*" A. Andouard, in his 'Noveaux Éléments de Pharmacie,' Paris, 1874, also uses asafœtida.

The corruption, if it may be so termed, of asa into assa was adopted into the Edinburgh Pharmacopœia in 1805,* as that issue contains a table in which the word assafœtida is mentioned as having been changed from asafœtida of the former editions. A somewhat similar tendency appears to prevail among some of the theologists in regard to the identical word under consideration. *Asa* occurs in the Bible as the proper name of two different individuals, the more important one being the third King of Judah. Although in both instances spelled and pointed in precisely the same manner, it is variously rendered into Greek by Josephus, the 'Septuagint' and the 'Alexandrian Codex' as Ἀσά, Ἀσάνος, Ὀσσά and Ἀσσά.

We are consequently forced to conclude that neither the derivation from the Latin *laser*, nor that from the Semitic *ăsă* justifies the use of the double consonant. We also find *asa* to be in use in the greater number of languages. In addition, we have shown that the best and most accurate writers in those few languages which sanction the use of *assa*, show a decided preference for *asa*.

The only argument which we have been able to find in favour of the duplicated form, is the derivation offered by Chambers's 'Encyclopædia' from the Persian ăsā, translated as stick, staff, baton, or bludgeon. Unsupported as this seems to be by other authorities, and in view of it being in direct opposition to the fact that both Persian and Arabic dictionaries render the same term into English with a single consonant, we cannot attach any importance whatever to this assertion. As an inevitable deduction from the facts which have been stated, we feel conscientiously bound to insist on the expunction of the barbarism *assa* from pharmaceutical literature, used either as a Latin or as an English word, and to recommend its exclusive substitution by *asa*.

* *Assa Fœtida* is used in the new 'London Dispensatory,' of which we have an edition (without title-page), printed in 1676.—Ed. Am. Journ. Pharm.

BRAZIL NUTS.

The last part of the *Transactions of the Linnean Society* is occupied by Mr. Miers's monograph of the *Lecythidaceæ*. Mr. Miers follows Lindley in erecting these plants into a distinct order, separated from Myrtaceæ by their alternate impunctate leaves, epigynous instead of perigynous insertion of the stamens, the large conspicuous petaloid development peculiar to the group, and the peculiar character of the fruit and seeds. The seeds of the genus *Bertholetia* are the well-known Brazil nuts of commerce. Dr. Berg asserts that the seeds are enveloped in a yellow fleshy pulp, which by desiccation leaves each enclosed in a distinct sort of cell; but Mr. Miers states that the fruits he has examined afford no trace whatever of any such pulp; and that Bonpland, Poiteau, and Schomberg, who examined them in a living state and gave abundant details concerning them, are all silent as to the existence of this pulpy matter. We have, moreover, direct evidence on this point in a specimen belonging to the Linnean Society, where a cluster of five seeds, evidently the contents of one cell, are agglomerated very closely together upon a portion of the columelles without the slighest trace of any pulp or any funicle; and affording, therefore, strong proof of the inaccuracy of Berg's statements. The particular tree which yields the nuts is separated by Mr. Miers from the older species of Bonpland, *B. excelsa*, under the name of *Bertholetia nobilis*, distinguished by its loftier growth, its immense trunk bare to a great height, stouter branches, leaves of a more rufescent hue, with more numerous closer nerves, more reticulated, or much shorter petioles; in its broader panicle with several long branches spreading horizontally; and in the rounder and more entire lobes of the calyx.

The quantity exported from Pará alone amounted in six months of the year 1853 to 18,862 alquieres, and from Manáos, on the Rio Negro, to 9,976 alquieres. This would correspond to an average annual export of 2½ millions of the fruits, or 50 millions of the seeds, measuring about 60,000 bushels; and this does not include the large quantity exported from the Rio Orinoco, Demerara, Cayenne, Maranhao, and other places. Their value in Brazil is about 30*s.* per bushel. The hard fruits which fall to the ground are broken in the forest by Indians, where a man and a boy will break about 300 of them daily. The kernels of these nuts, broken in a similar manner, are subjected to pressure, when they yield an oil greatly esteemed for domestic purposes and for export, each pound of the kernels yielding 9 ounces of the oil, valued at 2*s.* per lb. This oil consists, according to Martius, of 74 per cent. of elæine, and 26 per cent. of stearine. The finely laminated inner bark of the trunks is also a valuable article of commerce, especially adapted for the caulking of ships and barges, being worth about 18*s.* per cwt. The tree is about 130 feet high, with a trunk 14 feet in diameter up to a height of 50 feet, and quite bare to the height of 100 feet; its leaves are from 10 to 15 inches long; the fruit globular and 6 to 6½ inches in diameter. The question naturally arises, How do the seeds germinate and strike root, confined as they are in the pyxidium as in an inextricable prison? It is evident that they cannot find an exit through the opercular opening; nor can they escape by any other means than the rotting on moist ground of the pericarp which is ¾ inch thick. It probably requires three years' exposure to the sun and moisture before so thick a shell could decay sufficiently to allow of the liberation of the seeds, and then, perhaps, another year's exposure before the thick testa of the seeds could rot sufficiently to allow the embryo to germinate. This shows an extraordinary power of vitality in the embryo, which seems to remain four or five years in a dormant state. Oily seeds are generally supposed to ferment and decay soon, but that is perhaps, Mr. Miers suggests, when the oil cells are contained in albumen; here, however, we find a reverse condition. It is stated that when an embryo of the *Bertholetia* is extricated and planted under the most favourable circumstances, it takes a whole year before it begins to germinate; this may possibly be due to the large amount of stearine in the oil-cells, which preserves it from decay.

The tree which yields the Sapucayo nuts of commerce is separated by Mr. Miers from *Lecythis ollaria* of Linnæus, and *L. Zapucayo* of Aullet, and named *Lecythis usitata*.

The Pharmaceutical Journal.

SATURDAY, MARCH 13, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTERS, THE CALENDAR, AND THE BENEVOLENT FUND.

THE publication of the elaborate tables presented by the Registrar to the Council at its meeting in February, also of the Registers of Pharmaceutical Chemists and Chemists and Druggists, and of the Calendar of the Pharmaceutical Society for 1875, affords a suitable opportunity for again directing attention to the statistical history of pharmacy in Great Britain, and of comparing the figures with those of last year.

The Registrar reports that the total number of persons on the Register of Chemists and Druggists on the last day of 1874 was 13,286, of whom 2347, or 17·66 per cent., were pharmaceutical chemists, and 10,939 were chemists and druggists. The gross total in the previous year was 13,216, of whom 2374, or 17·96 per cent., were pharmaceutical chemists. These figures show that whilst there has been a decrease of 27 pharmaceutical chemists, the chemists and druggists have increased in number by 97, or sufficient to make up the deficiency in the gross total caused by the decrease in pharmaceutical chemists, and to increase it to 70 beyond that of the previous year. The total number of persons added to the Register during 1874 was 103 less than in the previous year, being 458 against 561 in 1873; notwithstanding that the candidates for the Minor and Modified examinations, the passing of which would have entitled them to be placed upon the Register, increased from 936 in 1873 to 1243 in 1874.

As has been before pointed out, the decrease in the number of pharmaceutical chemists, although much to be regretted, is due to the fact that that Register is being diminished by the removal of both the examined and unexamined classes, whilst it is recruited only by persons who have passed the Major examination. For the first time, however, the number of examined Pharmaceutical Chemists is this year in excess of that of the unexamined. The numbers are—examined, 1207, or 9·1 per cent. of the whole body of chemists and druggists; unexamined, 1138. Of the 10,939 persons who are not pharmaceutical chemists but are now on the Register of Chemists and Druggists, 1694, or 15·48 per cent., are there by virtue of having passed the Minor examination, against 1400, or 12·91 per cent., last year.

The following represents these figures in a tabular form, and gives the proportion of each class to the total number on the Register :—

	1874.				1875.			
	Number.		Per cent.		Number.		Per cent.	
Pharmaceutical Chemists :—								
Non-examined	1195	2374	9·04	17·96	1138	2347	8·56	17·66
Examined . .	1179		8·92		1209		9·10	
Chemists and Druggists (only) who have passed the Minor . . .		1400		10·59		1694		
Remainder, including those who have passed the Modified . . .		9442		71·45		9245		
Total		13,216		100·00		13,286		100·00

If we turn to the proportion which the number of persons connected with the Pharmaceutical Society bears to the whole number of Registered Chemists and Druggists, it is satisfactory to notice first that the decrease in the Pharmaceutical Chemists Members of the Society has not been commensurate with the decrease on the Register, the number being now 2101 against 2119, or only 18 less. Of the 2347 Pharmaceutical Chemists on the Register, 2101, or 89·77 per cent., are Members of the Pharmaceutical Society, against 89·25 per cent. last year. Of the remaining 10,939 chemists and druggists on the Register, 814 are connected with the Pharmaceutical Society as Chemist and Druggist Members, 459 as Associates in Business, and 830 as Associates not in Business, making together a total of 2103, or 19·22 per cent. against 1974, or 18·20 per cent. last year. These figures show that of the whole number (13,286) of persons on the Register of Chemists and Druggists, 4204, or 31·65 per cent., are connected with the Pharmaceutical Society, being an increase of 111, or 0·66 per cent. The Registered Apprentices subscribing to the Society have increased from 727 to 795.

	1874.		1875.	
	No.	Per ct.	No.	Per ct.
Pharmaceutical Chemists Members of the Society .	2119	89·25	2101	89·77
Other Registered Chemists and Druggists connected with the Society . . .	1974	18·20	2103	19·22
Total number of Registered Chemists and Druggists connected with the Society	4093	30·97	4204	31·65
Registered Apprentices subscribing to the Society .	727	...	795	...

One very gratifying feature of the statistics compiled by the SECRETARY, is the marked testimony contained therein to the wisdom of the step which was taken by the Council in February last year with respect to the Benevolent Fund. The effect of the decision to allow subscribers of five shillings to vote in virtue thereof at the election of annuitants has been to nearly double the number of subscribers of that amount. This increase, moreover, has not resulted in any decrease in the number of subscribers of larger sums; on the contrary, here there has also been a marked increase. In 1873, the gross amount received in annual subscriptions to the Benevolent Fund was £743 11*s.* 3*d.*, from 1228 subscribers, and the figures were practically the same in the previous year. In 1874, however, 1598 annual subscribers contributed £915 3*s.* 6*d.*, showing an increase of £171 11*s.* 9*d.*, and 370 subscribers.

Although this result is satisfactory so far as it goes, we cannot refrain from pointing out that even now the number of persons subscribing to the Benevolent Fund is in striking contrast to the number of persons upon the Register of Chemists and Druggists, viz., 1,470 to 13,286, or only 11·06 per cent. And if it be noted that 1,114 of the subscribers are found amongst 4,343 persons connected with the Pharmaceutical Society, leaving amongst the remaining 8,990 registered chemists and druggists, only 356 subscribers, 3·96 per cent., or less than 1 in 25, the disparity is still more remarkable. To seek no further for causes, it is probable that this apparent indifference is due partly to misconception or ignorance in respect to the true nature of the Fund, and partly to the absence of the opportunity and reminders for transmitting subscriptions which occasional communication with the SECRETARY upon other business presents to the members of the Society. However this may be, it is evident that the Fund might be materially benefited if in each district the Local Secretary, or some other influential gentleman, would undertake the duty of bringing the claims of the Benevolent Fund periodically before the chemists and druggists who are not connected with the Society. The fact that of the £423 distributed in temporary relief during 1874, nearly one-half went to persons who were *not in any way connected with the Society*, would furnish them with one strong argument as to its catholicity, whilst the gratuitous administration of the Fund, with expenses confined to a few pounds yearly for stationery and printing, would yield them another as to the economy of its application.

THE ALLEGED PRESENCE OF COPPER IN PICKLES.

ABOUT three months since (see before, p. 515), the commencement of proceedings against three persons residing in Staffordshire, for the sale of pickles adulterated with copper, was reported in this Journal. In each case the presence of copper was disputed and the hearing was adjourned to allow of an analysis being made by an analyst appointed by the court. We have just received information that in two at least of the three cases the summonses have been withdrawn. Presuming that this information is true we are of opinion that such a termination to a prosecution is unsatisfactory to the public in whose name it was initiated and unfair to the tradesmen whose reputation has been impugned: If, after three months' consideration, the conclusion has been arrived at that the evidence does not support the charge of adulteration it is only fair to the accused that the imputation should be withdrawn in court as publicly as the accusation was made. If, on the other hand, the offence charged can be proved, the case after being once opened ought not to be withdrawn from a magistrate's decision. This is not the only occasion on which the sole satisfaction a tradesman has had for weeks of anxiety and sometimes considerable expense has been the information that a summons has been quietly withdrawn.

EXEMPTION FROM JURY SERVICE.

IT would appear that there is little probability that the long-deferred hope of chemists and druggists to enjoy exemption from serving on juries will be gratified during the present Parliamentary session. On Tuesday last, in reply to a question, Mr. LOPES, who had charge of the Juries Bill during last session, said that it was not his intention to reintroduce it this session, as the causes still exist which prevented it from passing last year.

SPURIOUS SENNA.

IT is certainly not very flattering to English pharmacists to receive convincing proof of somebody's faith in their "gullibility and ignorance." But we learn from the last issue of Messrs. SOUTHALL, Bros. and BARCLAY'S 'Price Current,' which contains some "Hints on the Selection of Drugs," that notwithstanding Professor BENTLEY'S evident doubt of the probability of such an event, "some hundreds of tons of spurious senna are in the market at the present time, which appear to be without doubt the leaves of *Cassia brevipes*, D.C." Under these circumstances, it will be as well to remind our readers that this spurious senna has been described and figured by Mr. HOLMES, in the number of this Journal for the 6th of February. Messrs. SOUTHALL offer to send a few leaves to any one wishing to possess a specimen.

EARLIER CLOSING.

THE chemists and druggists of Oldham have advertised their intention in future to close their establishments on Tuesdays, Wednesdays, and Thursdays at 8 p.m.; on Mondays and Fridays at 8·30 p.m.; and on Saturdays at 10·30 p.m.

The name of JOHN PEARSON BELL, Esq., M.D., has been added to the Commission of the Peace for Hull. Dr. BELL was formerly, for a short time, in business as a chemist and druggist in Hull, as was also another gentlemen recently placed on the Commission, Mr. Alderman SEATON.

MR. EDWARD MOORE, pharmaceutical chemist, and formerly a student in the Society's School of Pharmacy, has been appointed Public Analyst for East Sussex. Mr. MOORE has also for some eighteen months past held the post of Public Analyst for Brighton.

IN the last number of the *Journal of Botany*, Dr. HANCE describes a new species of *Ribes*, *R. (Grossularia) macrocalyx*, from the neighbourhood of Pekin, the fruit of which is largely eaten by the Chinese.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

The fourth meeting of the present session was held in the Society's rooms, Edinburgh, 119*a*, George Street, on Friday evening, March 5th, at half past eight o'clock. Mr. William Gilmour, President, in the chair.

Chrysarobine, or Goa Powder.

BY D. S. KEMP, BOMBAY.

Mr. H. C. Baildon communicated a paper which he had received from Mr. D. S. Kemp, of Bombay, on Chrysarobine (formerly Goa Powder), a drug imported into Bombay from South America :—

Under the name of 'Goa Powder,' a drug, of which chrysarobine is the present representative, used to be imported into Bombay by Goanese traders as a remedy for Indian ringworm. It long attracted the notice of leading medical men, but was believed to be a nostrum rather than a natural production.

In 1863 I transmitted a specimen of it to Mr. Hanbury, F.R.S., along with an account of it, and the latter was published in the *Pharmaceutical Journal* of February, 1864.

As met with then, the powder was generally of a very dark chocolate or maroon colour, a state resulting from lengthened exposure to air and moisture, and in which half the activity of the original drug had been destroyed. Under these circumstances and after some trouble I succeeded in tracing its source and obtaining fresh importations, and my firm then adopted the name 'chrysarobine' for the substance as imported by us.

Chrysarobine is much more active medicinally than the old 'Goa Powder.' For an account of its therapeutic properties I refer to a paper by Dr. Fayrer, C.S.I., in the *Medical Times and Gazette* of October 24th, 1874, and for its chemical history I have much pleasure in submitting the following paper by Professor Attfield, to whom I am greatly indebted for the attention he has bestowed on the investigation. Indeed, the results he has obtained are so interesting that I cannot refrain from making them known.

Professor Attfield's paper will be found at p. 721.

Specimen of the wood and chrysarobine itself, though expected, had not arrived at the time of meeting.

A hearty vote of thanks was awarded to Mr. Kemp for sending the paper, and Mr. Baildon for bringing the subject before the Society.

Mr. William Gilmour then read the following on Gurjun Oil :—

Gurjun Balsam.

BY WILLIAM GILMOUR.

Gurjun balsam, or as it is sometimes called, wood oil, though exciting little more than a passing notice, has been known for some considerable time, it having been noticed, so far as I am aware, for the first time more than twenty years ago in the pages of the *Pharmaceutical Journal*, as a supposed new kind of balsam of copaiba.

It was correctly traced some time later to its sources by Mr. Hanbury, who also mentioned some of its peculiarities and distinguishing characteristics, comparing it with balsam of copaiba, to which it is closely allied, and which it strikingly resembles.

It is obtained by incision from the *Dipterocarpus lævis*, and other trees of allied genera—indigenous in the hot damp Indian forests—and can be obtained in such quantities that the natives employ it for many of the purposes to which we in this country put some of the more common oils.

I have been induced to call your attention to this substance from the most remarkable results obtained by its use, first in the treatment of leprosy in India and since then in our own country in cases of skin disease. Through the kindness of Mr. Wm. Dougall, brother to the discoverer of its important therapeutical effects in cases of leprosy, I was lately afforded a perusal of his official report to the Indian Government on the subject—a report at once so exceedingly interesting in itself and valuable in its results that I felt assured a very brief summary of it would prove acceptable to you.

Passing over, then, Dr. Dougall's account of the condition in which he everywhere found that most miserable and wretched of all the many miserable and wretched in India, the leprous, together with his earlier treatment and experiments for their alleviation, we come to the point at which, by a happy thought (for it seems to have been nothing more), he was induced to try the effects of a course of this balsam. Noticing a decided mitigation of all the more marked and worse characteristics of the disease under its influence, he was encouraged to begin a more extensive and systematic use of it in the Haddo Leprous Hospital, Andaman Islands.

Here, as a palliative remedy, the gurjun balsam very soon asserted it power, the most extraordinary results ensuing in every case brought under its influence. Of twenty-four cases which Dr. Dougall had under treatment in this hospital during the six months previous to the publishing of his report,—many of these cases of the very worst kind,—every one of them had decidedly benefitted by its use; *every ulcer, without exception, having healed up and not broken out again*; the most marked benefit, however, having been derived by those suffering from the anæsthetic form of the disease. Each one of the twenty-four cases is minutely narrated and dwelt upon in the report, and however bad or hopeless they might appear at the commencement of the treatment with the wood oil, they yet soon yielded to its power. One, for example (just taking a case at random from the report), had been seven years a leper, had anæsthesia of right fore arm and both feet; the whole of the hands had been eaten away, as also portions of two toes of the right foot, and the stumps were open sores when the oil was given to him for the first time. In a few months after, sensation had been recovered in all the parts formerly affected, and all the sores had quite healed up.

Another had anæsthesia of the whole surface of the body, including both hands and feet—the face and ears only being excepted. The ulcers soon healed up, and sensation was shortly after restored to the whole body; this man being apparently in perfect health, and able to run, walk, or work with any man of his age. The parts affected heal evenly, the new skin being just a shade lighter in colour than the normal tint.

Its mode of use is somewhat novel. Dr. Dougall, after trying various plans, ultimately fixed upon a mixture of equal parts of lime water and the balsam, as being in every respect the most suitable; and this emulsion he not only gives internally, but uses also freely as a liniment.

The liniment was rubbed over the whole body night and morning, whilst the emulsion was given internally to the extent of four drachms three times in the day, in which doses he found it operated as a mild tonic, exciting at the same time a distinct diuretic and evacuant effect.

The interest which these results have excited may be inferred from the fact that Government, as lately reported in the *Pharmaceutical Journal*, has called particular attention to the report, with the view of giving it the widest publicity possible, inviting at the same time the co-operation of all local governments and administrations towards the extension of its use, with the request also that careful reports on the results maybe submitted at the end of a year.

Whether this remedy may ever become popular in this country for skin diseases, or whether it may be as successful here for such as it has been in India for the more inveterate leprous form, are questions which time and experiment alone can determine. But, meantime, it is exciting no little interest in medical circles, and Professor Erasmus Wilson lately reported the most encouraging results from its use in cases of painful eczema, in lupus, and in cancer; and further reported the case of a lady, who had not obtained sleep without the use of narcotics for weeks, until the liniment was applied, when she was relieved of all pain and obtained natural sleep.

After a few remarks by some of the members present, a vote of thanks was proposed by Mr. Young, seconded by Mr. Baildon, and cordially awarded to Mr. Gilmour for his communication. Mr. Blanshard stated that some time ago a specimen of what was called Rangoon wood oil, said to be used in making or adulterating balsam copaiba had been sent to their firm, which in appearance was not unlike the sample of Gurjun oil submitted, and which he would have much pleasure in showing at the next meeting.

Dr. S. Macadam then read the following supplementary paper on the composition of country milk :—

On the Composition of Country Milk.

BY DR. STEVENSON MACADAM, F.R.S.E., LECTURER ON CHEMISTRY, ETC., ETC.

The present communication may be regarded as supplementary to the paper read by me before the Society on the 26th of March, last year. At that time I had analysed a large number of samples of milk taken from cows in dairies in and near Edinburgh ; in other words from dairies specially arranged for the supply of milk to town, and where the animals were more or less fed with artificial food. The general results arrived at from the analysis of 66 samples of milk, taken from 46 cows, were that the average quality of genuine town milk was as follows :—

Average Town Milk.

Specific gravity, 1032·1.

Total solids by weight	. . .	12·27	per cent.
Solids not fat	„	9·69	„
Fat in solids	„	2·58	„
Ash in solids	„	0·71	„

During the month of June I made arrangements for the sampling of country milk yielded by cows fed on the best natural pasture. The farm selected was situated on the northern bank of the Tweed, and alike from the natural capabilities of the soil and the season of the year, the grass was in the best condition, and was luxuriant and nutritious. The cows were pastured in the same fields, and milked at the same time of day. In all respects they were subjected to the same diet and treatment. Samples were taken from the whole morning runnings of each of seven cows, and the analyses were made to determine specific gravity, total solids, solids not fat, fat or butter, and ash. The experimental results, calculated in each case to percentage proportions, are given in the following table :—

Analyses of Samples of Country Milk.

Cow. No.	Specific gravity of milk.	Total solids per cent. by weight.	Solids not fat per cent. by weight.	Fat in solids p.c. by weight.	Ash in solids p.c. by weight.
1	1032·3	13·17	9·87	3·30	0·73
2	1031·8	11·85	9·63	2·22	0·65
3	1033·5	12·96	10·09	2·87	0·69
4	1033·4	12·47	9·88	2·59	0·80
5	1034·7	12·25	10·41	1·84	0·69
6	1030·8	12·86	9·99	2·87	0·73
7	1029·2	13·88	9·42	4·46	0·68
Average of 7 samples	1032·2	12·77	9·89	2·88	0·71
Lowest . .	1029·2	11·85	9·42	1·84	0·65
Highest . .	1034·7	13·88	10·41	4·46	0·80
Difference .	5·5	2·03	0·99	2·62	0·15

It will thus be observed that the samples of milk yielded by the different cows varied much in composition, especially in reference to the percentage of fat or butter, which was more than twice as great in one sample as compared with another. Taking the proportion of fat assumed last year by some chemists as the standard quantity, viz., 3·2 per cent., only two of the seven samples of country milk analysed by me came up to the arbitrary standard, and consequently only the two samples would have been reported as genuine, whilst the remaining five samples would have been reported as, more or less, mixed with skimmed milk. The total solids were likewise deficient in three of the seven samples. The average quality of the seven samples of genuine country milk was as follows :—

Average Country Milk.

Specific gravity, 1032·2.

Total solids by weight	. . .	12·77	per cent.
Solids not fat	„	9·89	„
Fat in solids	„	2·88	„
Ash in solids	„	0·71	„

These proportions are up to the assumed standard in everything but the fat, and the deficiency in the latter (2·88 per cent. instead of 3·2 per cent.) would have been sufficient to have placed the whole runnings of this dairy in the position of being reported as containing only 90 per cent. of genuine milk, and mixed or adulterated with 10 per cent. of skimmed milk ; whilst if the lowest amount of fat obtained from any one of these milks be taken, viz., 1·84 per cent., this sample of undoubted genuine milk from a country dairy would have been reported to be made up of 57·5 per cent. of genuine milk, and as much as 42·5 per cent. of skimmed milk.

These results, taken from a country farm dairy at the best season of the year for natural feeding, clearly prove that the assumed arbitrary standard of quality of milk is alike too high for country as well as for town milk, and probably, had the milk been taken from the cows for analysis in September or October, when natural pasture is not so nutritious, the quality of the milk would not have been so good as it was found in June.

A hearty vote of thanks was awarded to Dr. Macadam for his valuable communication.

Mr. Baildon then submitted a very interesting paper on the history of a few important drugs known to the Ancients, and still in use in modern pharmacy, consisting principally of extracts from Professor Flückiger and Mr. Hanbury's 'Pharmacographia.'

Mr. Ainslie proposed a vote of thanks to Mr. Baildon, which was carried with acclamation.

The following contributions to the Museum and Library were laid on the table and thanks voted to the donors :—

Pinus Tæda, Torch Pine, or Pitch Pine of United States, a chief source of American turpentine, from Professor Christison ; 'Proceedings of the American Pharmaceutical Association for 1874'; 'Proceedings of the Royal Society,' from Mr. Mackay ; 'Canadian Pharmaceutical Journal,' from Toronto ; 'The Pharmacist,' from Chicago ; 'Journal of the Chemical Society,' from Mr. Mackay.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eighth general meeting was held at the Royal Institution, on Thursday evening, February 25th. The President, Mr. A. F. Mason, F.C.S., in the chair.

The following donations were received :—'Proceedings of the American Pharmaceutical Conference,' 'Proceedings of the Liverpool Literary and Philosophical Society,' 'The Pharmaceutical Journal,' 'The American Pharmaceutical Journal,' 'The American Chemist.' A vote of thanks to the donors was unanimously passed.

Mr. Redford described a new form of water-bath which he had found useful, and, at the request of the meeting, promised to bring on a future occasion. Mr. Mason exhibited a sample of jaborandi, and also one of Persian opium. The opium contained 8 per cent. of morphia, and was employed to make the alkaloid, its smell and appearance being different from ordinary opium. He also alluded to a case in which a solution of 50 grains of muriate of morphia had gelatinized. It was supposed to have been adulterated, but on examination it appeared that the gelatinization was due to the separation of excessively minute crystals, the liquid becoming clear again on heating.

The Secretary read a letter from Mr. Farries, expressing his regret that he was unable to attend and read a paper as he promised, in consequence of ill health.

The President then called upon Mr. J. T. Armstrong, F.C.S. (who had kindly offered to take Mr. Farries's place), to read a paper on "A College of Research for Liverpool."

The author is of opinion that the attention of the present generation is too exclusively devoted to present results and things that give an immediate return, forgetful that it would not hold the position it does had its predecessors thought in the same way, and been as selfish. Referring to the interest in the subject of original research that has recently been manifested in the Universities, Mr. Armstrong said the Universities would never be able to deal with this question in a proper manner, although they could do much to help it forward by properly training and selecting men who would devote themselves to the work. He considered that Liverpool had hitherto done little but reap the benefit without doing any of the work. Liverpool should lead the way in the matter and establish a College of Research, and before long discoveries valuable to the human race would be the result. The plan suggested by Mr. Armstrong is to have a building furnished with a well-stocked laboratory and reference library, to be superintended by a professor of chemistry who has shown that he fully understands the importance of original research, and a part of whose "time would be spent in training the masses to have a liking for science by giving courses of lectures conducted in the same manner as at the Royal Institution, London." He is also to seek out investigators and to train assistants to aid those engaged in research. Men who have made discoveries in a direction requiring further investigation are to be invited to work in the laboratory, receiving a sufficient remuneration to keep them while so engaged, and eventually, according to results. All work done is to be published periodically, and communicated to the supporters of the College and the learned societies. Mr. Armstrong, in conclusion, said that he believed it was only necessary to make the claims of such an enterprise known in Liverpool, and men would be found ready to devote time and money in carrying it out to a successful issue.

A short discussion followed in which Messrs. Davies, Shaw, and the President took part, and the proceedings terminated with a vote of thanks to Mr. Armstrong.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Assistants' Section.

The sixth meeting of session 1874-75, was held in the West Hall, Anderson's University, on Wednesday, March 3rd, at nine p.m. The President, Mr. John C. Hunter, A.P.S., occupied the chair. The minutes of last meeting having been read and approved of, the Chairman introduced James McCann, Esq., Ph.D., who delivered a very interesting lecture on geology, with special reference to the structure of Scotland, and especially that of Kincardineshire, Aberdeenshire, Ayrshire, and Dumfriesshire. In speaking of the metals which occur throughout Scotland, Mr. McCann said that "Gold is always found in the metallic form, or as a pure native metal. The metals which occur to any workable extent in Scotland, or which have been worked in former times, are—mercury, cobalt, zinc, manganese, antimony, lead, copper, iron, silver, and gold. Several of these are found in such small quantities as to be of no economic value. In Scotland the quartz rock is reported to contain two ounces of gold to every ton of mineral, therefore there is no reason to doubt that should chemistry, which has made such prodigious advances within the last century, be successful in discovering some easier and cheaper method of separating the metal from the stone, no limits can be set to the riches of the mountain land of Scotland. At present the expense of extraction by crushing and other means is so great as to be unremunerative; but as all mechanical difficulties are giving way to the progress of human invention, the presumption is that the mineral kingdom, so extensively explored by geology, will also become more obedient to the analytical processes and resolving power of science. Chemistry has already done wonders in separating as well as in combining, in subduing the most flinty, refractory mass to ductility and softness, and hence we may yet find in the fable of Prometheus taking fire from heaven to animate his man of clay, an emblem of the transmuting powers of chemistry in dissolving the rocks of the earth and vivifying their opaque dust with the radiant lustre of the precious metal."

After some remarks from a few members, the Chairman proposed a hearty vote of thanks to Mr. McCann for his instructive lecture, which was warmly responded to.

The President exhibited a large number of beautiful specimens of igneous and aqueous rocks and fossils, from the lime, coal, and clay-bed formations.

THE ASSOCIATION OF CHEMISTS AND DRUGGISTS FOR WOLVERHAMPTON AND DISTRICT.

An ordinary monthly meeting of the members and associates of this Association was held on Thursday evening, in the Committee Room, Agricultural Hall, the President (Mr. W. Fleeming) in the chair. There was a good attendance of members, including many assistants and students, who appeared to take great interest in the proceedings of the evening, which included an address by Mr. Wentworth Lascelles Scott, F.C.S., on the Adulteration of Food and Drugs Bill, as affecting chemists and druggists.

The President, in commencing the business of the evening, congratulated all present on the progress which the Association had made since its formation a few weeks ago, and the good and apparently sound position that it had already attained. He must say that at the outset he did not feel quite so sanguine, as some others did, as to the success of the Association, and he was therefore all the more gratified at the success which had attended its operations, for he found that a great deal of interest was taken in the proceedings of the Association, not only by the members themselves, but by many of the general public outside. He trusted that this interest would continue to be sustained, for he was quite sure that the Association and the classes which had been started in connection therewith would be of the utmost assistance to their young friends—the assistants and apprentices—in prosecuting their studies and obtaining that knowledge which was so necessary to them before they could take the position to which many of them aspired, as recognized chemists and druggists.

After the minutes of the last meeting had been read and confirmed, Mr. F. J. Barrett, F.C.S. (the junior hon. sec.), read over the following list of donations in money, books, and instruments which had been received since the last meeting towards the formation of the proposed library and museum:—Mr. Fredk. Weaver, (Tetenhall), £5; The Right Hon. C. P. Villiers, M.P., £1 1*s.*; Mr. T. M. Weguelin, M.P., £1 1*s.*; Mr. Peter Squire, 'Companion to the Pharmacopœia,' and 'London Hospital

Pharmacopœia;' Mr. John Balcomb, Horsley's Milk Testing Apparatus; Mr. John Griffin, F.C.S., 'Chemical Recreations,' 1 vol., 'Chemical Handicraft,' 1 vol., 'Testing of Wines and Spirits,' 1 vol., etc.

On the motion of Mr. W. Y. Brevitt (the senior Hon. Sec.), the thanks of the meeting were accorded to the donors.

The following gentlemen were then duly elected as "Honorary and Corresponding Members" of the Association:—Mr. Fredk. Weaver (Tetenhall), Mr. W. L. Scott, F.C.S. (County Analyst), and Mr. J. E. Morris, F.C.S.

Mr. Brevitt, in proposing the name of Mr. Scott, said it was due to him to state that, although this association had started so recently, yet the desirability of such an association being formed was first suggested by Mr. Scott some years ago for the purpose of uniting themselves together against the vexatious proceedings and annoyances to which in the then state of the law, chemists and druggists were liable. Circulars were sent round to the various chemists and druggists in the town soliciting their co-operation, but it was hardly thought at that time that they were in a position to commence such an association, and the movement was allowed to fall through. The object with which the Association had now been started was purely an educational one, to supply a want that was much felt, by the formation of classes, and other means, by which the assistants and pupils would have opportunities afforded them of prosecuting their studies in the science of chemistry. Mr. Brevitt further stated that until the council of the Association had decided upon a suitable room or rooms for the purpose, he had placed a room at his premises in Darlington Street at their disposal, where classes for the students were held on each Tuesday and Thursday evening; and on Friday evenings the books which had been given and purchased for the library of the Association, the materia medica specimens, and specimens of plants, etc., would be laid on the tables for their inspection and study. He would suggest to the council that prizes should be given at the end of each session to the most successful student in each class.

Three ordinary members were then elected.

The Chairman remarked that the members of the Association were very much indebted to their joint secretaries for the zealous interest they displayed in the work of the Association, and the arrangements they made to promote its success. He was very glad that amongst other things they had arranged for the delivery of a course of lectures, one of which they were to have that night from Mr. Scott, on the Food Adulteration Act. He did not know what views Mr. Scott was going to express, but he might say for himself that under the old law chemists and druggists were continually exposed to all kinds of harassing and vexatious proceedings, although he was glad to say that in Wolverhampton they had been singularly free from such proceedings. So far as he had read the Bill introduced by Mr. Sclater-Booth, he thought the difficulties and anomalies complained of in the old law were fully met. Of course there were to be found a few black sheep here and there in every profession, and it was only right that the public should be protected from them. Now the bill of Mr. Sclater-Booth was intended to afford this protection, and at the same time afford equal protection to the trade against those harassing and vexatious proceedings, to which, under the old law, they were liable at any moment.

Mr. Scott then proceeded to deliver his address. He said he wished in what he desired to say to them to make a few observations, first, as to the inconsistencies in the old or present law with respect to the adulteration of food and drink, etc.; and next to point out what he deemed to be inconsistencies in the Bill of Mr. Sclater-Booth. The present law on the subject was unfortunately not confined to one Act of Parliament, but extended over three or four, and owing to the different constructions put upon these Acts by different lawyers and different magistrates, chemists and druggists in different parts of the kingdom had, at times, been very hardly dealt with, and had been most inconsistently convicted. Mr. Scott then proceeded to refer to what he considered the two great faults of the Bill now before Parliament: firstly, that in convicting any tradesmen of certain offences there specified, the magistrates were permitted no discretionary power in apportioning the amount of the fine in accordance with the circumstances under which the offence was committed. As for instance, the 7th section of the Bill enacted that "no person shall sell any article mixed with things more than was ordinarily required for the purpose under a penalty of 10*l*." The same section provided that "any person who sold any article of food which by the usage of trade was sold in the mixed state unless the ingredients were mentioned in the proportions required by such usage should be subjected to a penalty of 20*l*." Then the 9th section said, "any person who knowingly, and with the intent that the same might be sold, altered any article of food in part or whole so as to make it unwholesome would be liable to a penalty of 10*l*." In each case the magistrate had no option, if the offence were proved, but to inflict the full penalty; that he thought a great hardship. Then, in the next place, a special provision was inserted in the Bill to the effect that all tea imported into this country should be examined analytically at the port of entry, and if found injuriously adulterated should be confiscated and destroyed; and if adulterated, but not injuriously, the same might be allowed to be sold as a mixture. Now, he considered that this provision ought to be extended to all articles of food, drink, or drugs, upon which duty was received by the Government.

A lengthy discussion followed upon these points, and ultimately the following resolutions were passed:—

(1) "That in the opinion of this Association it is expedient that the fines imposed for offences under this Act shall not be uniform, as proposed, but shall be left to the discretion of the magistrates as at present, the maximum penalty being named in the Act, but that a lower penalty may be imposed."

(2) "That in the opinion of this Association the 'special provision for tea' (section 30) is just and right, but that the same provision should be extended to all articles of food, drink, and drugs, upon which a duty is charged and collected upon importation into this country."

The secretaries were instructed to forward copies of the resolutions to Mr. Sclater-Booth, M.P., Mr. A. S. Hill, M.P., Mr. Monckton, M.P., and the members for the borough.

A vote of thanks to Mr. Scott for his address, and to Mr. Fleeming for presiding, brought the proceedings to a close.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A special meeting of the above Society was held on March 5th. Mr. C. Hester in the chair. The Secretary, Mr. Druce, after reading the minutes, said the Association had received the Calendar and Journal from the Pharmaceutical Society. Mr. Wallis presented a specimen of jaborandi, and specimens of sagapenum and antimon. vitrum were also shown.

Mr. Wallis then read a paper on the Phenomena of Life. He commenced by stating that the natural bodies by which they were surrounded were arranged under two great classes, the inorganic and organic, the living and the lifeless; the question, therefore, immediately arose, 'What is Life?' What is that of which the effects appealed so constantly and forcibly to their senses as to render the distinction thus made one of their earliest and almost unconscious observations? In the study of organic bodies they must be struck with the vital union of their constituent particles which was totally unlike every other combination of matter, differing most essentially from either chemical or mechanical combination. In crystals or other inorganic bodies they observed determinate and settled forms, while in organic bodies a perpetual change was going on by the agency of vital power; particles lately incorporated being thrown off while other foreign and inorganic substances were assimilated to be thrown off in their turn, life maintaining its triumph over the loss of dead matter, preserving for a time the identity of the animal or plant till vitality ceased and its operations gave way to the laws of chemical affinity. Death was, in fact, the conquest of the vital forces by the physical. Another fact deserving attention was that an animated being was the product of an antecedent, called its parent, which it essentially resembled, as like produced like; the lily did not aspire to the magnitude of the oak, or the lamb to the stature of the giraffe. On being minutely examined the internal organization of every living body exhibited a union of solids and liquids; the solid parts consisting of minute particles so arranged as to form fibres and tissues of various densities and structure, and everywhere pervaded by a circulating fluid from which the particles composing them are elaborated. When an attempt was made to investigate the intimate texture of the solids beyond a certain point they were foiled, no eye could scan, no instrument could follow the mystery of organic structure and its circulating fluid. Mr. Wallis then described the characters of the albuminous group, viz., albumen, fibrin and casein, and explained in a graphic manner the process of assimilation of food by animals and vegetables. He then stated that the primary and leading feature of vitality was the process of nutrition, and that process could only be exemplified by organic beings. In vain, however, did they ask, What was Life? If they applied to chemistry, they only learned from its researches that the elements of organic bodies were carbon, oxygen, hydrogen and nitrogen, and alkaline and earthy salts. Chemistry, potent over the vast empire of inert matter, was unable to ascertain what was life. Within its own kingdom it could analyse and combine, make solids fluids, and fluids solids; resolve bodies into their elementary gases, and recombine them. All this and more was in its power, but it could not recompose a single fluid or solid of any organic body. Here its penetration was baffled and its art at fault. If, then, chemistry could not ascertain the true nature of the constituents of organic bodies, neither could it discover the means by which they maintained their specific differences, not only as regarded the form but the quality of their substances—quality which widely differed even when the same nutriment was in each case received. The same soil, the same water, the same air may nourish the vine and the aconite, the rose and the hemlock; their very roots and leaves might intertwine, but their identity and specific properties would continue unaltered. Having alluded to the irritability of organic objects, and to the choking and hardening of the tissues as rendering death a necessary sequel of life, the author pointed out that with the cessation of the vital principle every phenomenon which distinguished between organic and inorganic matter ceased; the outer form might indeed remain for a shorter or more protracted period, but it remained no longer under the influence of the laws of life. Its component parts were the subjects of another empire; they formed new combinations and became lost and mingled with the elements around. To such a transition inorganic matter offered no analogy. Mr. Wallis concluded by saying that what life was even in its humblest form must remain inscrutable. The sphere of man was bounded, his researches were limited, and the hidden mysteries around and within him were too great for him to fathom. In the highest and noblest effort of man they might detect the weakness of his fallen nature, but in the works of God they had a revelation of his character; a mirror in which they might behold his infinite perfections.

After the discussion, which was rather lengthy, a hearty vote of thanks was passed to Mr. Wallis for his paper, and to the donors for the specimens and contributions.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 4th March, 1875. Professor Odling, F.R.S., in the chair. The usual business of the society having been transacted, a paper "On the Dissociation of Nitric Acid," by Messrs. P. Braham, and J. W. Gatehouse, was read by the former, and an experiment performed showing the action. Dr. Thudicum then addressed the meeting "On the Chemical Constitution of the Brain," exhibiting a large number of the products obtained from that organ. There were also papers on "Calcic Hypochlorite from Bleaching Powder," by Mr. C. T. Kingzett, and "On a Simple Method of Estimating Iron," by Mr. W. Noel Hartley. The meeting was finally adjourned until Thursday, 18th March, when Dr. Hofmann will deliver the Faraday lecture at the Royal Institution "On Liebig's Contributions to Experimental Chemistry."

NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE.

The Sale of Food and Drugs Bill.

At a meeting of the National Association for the Promotion of Social Science, held last evening in Adam Street, Adelphi, a paper was read by Mr. G. W. Wigner, Secretary of the Society of Public Analysts, on the subject of the recently introduced Bill for the Repeal of the Adulteration of Food Acts. The chair was occupied by Dr. Charles Cameron, M.P.

A discussion followed, in which Mr. Holborn, Mr. Sewell White, Dr. Muter, Mr. Helm, Dr. Bartlett, Dr. Dupré, and others took part. The questions brought forward related mainly to the difficulties which had been found to arise before magistrates in deciding between conflicting analytical testimony. One or two speakers treated the Bill from a trade point of view, dwelling on the hardship to small tradesmen, which they believed had sometimes arisen during the working of the Act at present in operation.

The subject of the nomination of a supreme court of appeal for disputed cases of analysis was also freely discussed; one gentleman arguing that such a body or institution should, to insure impartiality, be appointed without consultation of persons holding appointments under the Act; and others that the Society of Public Analysts itself should have a prominent voice in the matter.

Decided opinions were expressed against the appointment of medical officers of health as public analysts, on the ground that the successful pursuit of food examination required more time than such officers were enabled to devote to its practice, consistently with a proper performance of their other important duties.

The correctness of a so-called "classification of evidence," compiled and issued in the interests of the tea trade, having been impugned by Dr. Bartlett, Mr. Holborn, who announced himself as a joint author of the work in question, spoke to its absolute accuracy, and challenged proof of its incorrectness, which proof Mr. Wigner supplied by quoting several instances of repression or perversion of questions and answers bearing on tea.

Votes of thanks to the chairman and to Mr. Wigne brought the meeting to a close.

Parliamentary and Law Proceedings.

The Protection of the Names of Proprietary Medicines.

A case of considerable interest to patent medicine proprietors was argued before Vice-Chancellor Hall, on Thursday the 4th inst. The plaintiff was Mr. John Smith, chemist and druggist, of Lincoln, who is the proprietor of a mixture for the cure of coughs, colds, etc., known as "Pectorine." The defendant was Mr. Mason, also a chemist and druggist, of Rotherham. The plaintiff's bill of complaint alleged that he had invented and introduced to the public a cough mixture to which he gave the name of "Pectorine," a name which had never before been applied to any medicinal preparation. On January 7th, 1873, he registered at Stationers' Hall a label for the preparation, which was described as "Smith's Pectorine," and under this name was advertised in Lincolnshire and adjacent counties. By means of such announcements, and owing to its valuable properties, the cough mixture acquired a considerable reputation and a large and regular sale throughout England. In October, 1874, the label was altered by plaintiff to "Pectorine" only. In November, 1874, the plaintiff discovered that defendant was manufacturing and selling a cough mixture by the name of "Pectorine," and he thereupon instructed his solicitor to write to defendant warning him against doing so. The defendant replied that he had never heard of any other "Pectorine" than his own; but it was shown that he was for some time previously aware that plaintiff was the proprietor of a cough mixture known as "Pectorine." As he persisted in selling his preparation as "Pectorine," plaintiff filed the present bill in Chancery, praying that he might be restrained. The hearing occupied the whole of Thursday, and was argued by the learned counsel on both sides in the most exhaustive manner, the issue being regarded as one affecting the whole question of trade-marks.

The Vice-Chancellor, in an elaborate judgment, said the question to be determined was a reasonably simple one. The plaintiff's contention was that at the close of the year 1872, having invented and introduced to the public a cough mixture, he gave it the name of "Pectorine." This was undoubtedly a new name, as it had never been applied to any medicine before. He appropriated that as a trade-mark, by associating with it his own name; but the name "Pectorine" was invented for the purpose of giving a special character to the article. Having invented it, he registered the preparation on the 7th January, 1873 as "Smith's Pectorine." On the 24th October, 1874, however, the registration was altered to "Pectorine" only and this was plaintiff's title. On the 16th September, 1874, the defendant registered a medicine as "Pectorine," which preparation, as well as the name, it seemed, was his own invention, although it appeared that on the 15th September he was aware that the plaintiff claimed the name of "Pectorine." The question now to be determined, was whether defendant was entitled to use the name. One portion of the defence was that the word "Pectorine" was not capable of being appropriated as a trade-mark at all. It appeared to him (the Vice-Chancellor) as to the name that it was not a question of law, but of the ordinary understanding of mankind, whether or not the use of the word "Pectorine" for the first time applied to a particular article was a fanciful name. He considered it was a fanciful name, as nine-tenths of the purchasers of the article would probably not know the meaning of it. As to the defendant knowing that the name belonged to plaintiff, that was upon many authorities quite unimportant. It seemed to him that it was quite a misfortune he hit upon that particular name, yet notwithstanding this, the name, according to the more modern authorities, was a property belonging to the plaintiff. The Court having arrived at that conclusion, had only to ask itself this question—If this article is ordered by that name, will or will not the plaintiff be damnified by that being done? The question could only be answered in one way, namely, that the plaintiff would be damnified if orders were given for the article by that name, and those orders were liable to be executed, as they would be, by supplying the article, if defendant was selling his preparation under exactly the same name. Then it had been said that the name was originally "Smith," joined on to the name of "Pectorine," and that nothing short of using the whole description would be calculated to deceive; but this was not a correct view. The public understood it to be "Smith's Pectorine," but it did not follow that in every case where "Pectorine" was ordered by anybody who required to use it that it would be obtained by the retail agent from the original proprietor and vendor, Mr. Smith, at Lincoln. He (the Vice-Chancellor) had said that knowledge of the plaintiff's title was unimportant, and it seemed very unimportant for any other purpose now, because he still obtained the right to use the name. Therefore every act he had done since showed he was doing it with an actual intent and purpose to deceive, and as such must be liable upon that footing. After referring to several cases bearing upon the issue, the Vice-Chancellor said the article, "Smith's Pectorine," was one which, from its very nature, gradually forced its way into the market from one place to another, and from having at one time a certain limited amount of sale in a particular locality, gradually spread itself all over England. A person having a name as his property, had a right to protection in respect of it. Patent medicine vendors, as a rule, began with small beginnings, but in those beginnings they originally acquired the protection of a trade-mark. The plaintiff was perfectly entitled to the protection of the sale of his article, even at Rotherham, where, notwithstanding the defendant's medicine had had the start, he seemed to be getting a business as well as at other places. Therefore, he (the Vice-Chancellor) could not come to any other conclusion than that the plaintiff had made out his case for the protection which he asked, and he would accordingly grant an injunction forthwith.—*Lincoln Journal.*

Poisoning by Arsenic.

An inquest on the bodies of Henry, Mary, and William Chandler, who were accidentally poisoned by arsenic, was opened by Mr. G. H. Hull, at Elstead, on Saturday last. The Coroner, in opening the inquiry, said it was of the greatest importance not only to the people immediately concerned, but to the community at large, that the strictest investigation should be made into the circumstances of the present case. It seemed to him a very sad thing that a man should be allowed to obtain so easily and have in his possession so large an amount of arsenic. Had the law on the sale of poisons, which provided that arsenic should contain an admixture of Prussian blue, been properly carried out, he did not see how it could have been mistaken for flour, and it would be a subject for the most careful consideration of the jury as to whether that law had been violated or not. The inquest was adjourned till Wednesday, when evidence was taken from which it appeared that Chandler had been in the habit of purchasing arsenic in quantities of 10lb. at a time for sheep dipping. On Wednesday morning he mixed two or three spoonfuls of the compound with flour on a plate, and placed it on a shelf in the pantry, for the purpose of killing vermin. As it was not coloured, Chandler's daughter, in preparing the dinner, mixed the composition in a suet pudding. At dinner time she felt too unwell to partake of anything, and her mother recommended her to go upstairs and lie down. Shortly afterwards her father called her down and asked her if she had used the composition which he had placed in the pantry in making the pudding. She replied in the affirmative, upon which he exclaimed, "Good God! We are all poisoned." Messengers were quickly despatched to Godalming and Farnham for medical aid. Dr. Yate, of the former place, arrived at the house about 5 o'clock, when he found Mrs. Chandler dead and her husband and children in a dangerous state. He had the sufferers put to bed and applied the usual remedies, but William, Chandler's eldest son, died at 7 the same evening; and his father succumbed at half-past 1 the next morning. Mr. Griffith, chemist, of Farnham, said that when the deceased purchased the arsenic he said that it would be used for sheep dipping, and as the Act provided that upon such representation it could be sold in its pure state to the extent of 10 lb., he did not put any colouring in it. The Coroner said that the melancholy occurrence was evidently the result of an accident, and due to the carelessness of the man Chandler himself. He was strongly of opinion that there should be some alteration in the Act regulating the sale of arsenic, and that such large quantities should not be sold without being coloured. He believed that some colouring could be used without rendering the arsenic useless for sheep dipping and other purposes for which it was necessary, which would prevent it being mistaken for flour, as was the case in the present instance. The jury returned a verdict of "Accidental death," with a recommendation that means should be adopted for the colouring of all arsenic in future.

Reviews.

YEAR-BOOK OF PHARMACY, comprising Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign Journals, from July 1, 1873, to June 30, 1874. With the Transactions of the British Pharmaceutical Conference at the Eleventh Annual Meeting, held at London, August, 1874. London: J. and A. Churchill, 11, New Burlington Street. 1875.

The long expected and wearily waited for 'Year-Book of Pharmacy,' is by this time in the hands of every member of the British Pharmaceutical Conference. We have no desire to be exacting or even severely just with the editor, on whose shoulders the burden of complaint heaped together by a long delay must be placed,—his infirmity claims the rather our sympathy and kindly forbearance—but we would take this opportunity of pointing out to those whom it most concerns, that this second experience of even editors not being exempt from the ills of flesh, suggests the desirability of dividing the responsibility for a timely appearance of the 'Year-Book.' The very essence of the usefulness of such a volume as the one before us depends on its prompt publication at the close of the term embraced by its pages. In the present instance its appearance is contemporaneous with that of the eighth month of another year.

It is a handsome volume of 663 pages. The arrangement of the matter is the same as that already familiar to the members of the Conference. As to the matter itself, the short time we have been able to devote to an examination of it, induces us to offer our congratulations to the editor on the judgment which has guided his choice.

The volume seems to us to represent very fairly a year's progress in the three subjects denoted by the titles of the parts into which the 'Year-Book' proper is divided, viz., *Materia Medica*, *Pharmaceutical Chemistry* and *Pharmacy*. It is true there is a fourth part, *Notes and Formulæ*, but this we think may be considered subsidiary to *Pharmacy*. The book contains no omissions of importance, if we may so speak, and the abstracts, in those cases where the nature of a paper permits of abstraction, betoken on the part of the abstractor a keen perception of the merits of the original, and of the relation of the facts or suggestions to our every-day pursuits. It is with a feeling akin to pain, however, that we turn over page after page and see name follow name in almost unbroken succession, which is either continental or American. Why is this? Are our own prophets not honoured? or have we so few? We fear, the latter.

The editor rightly gives the first place in the list of achievements during the pharmaceutical year, to the published results of Hesse's exhaustive study of the cinchona alkaloids. The cinchonas have always absorbed a large share of the attention of pharmacists, and that they have received as much in 1873-4 as in any previous year, is evidenced by the contributions of Hesse, De Vrij, Bernatzik, Jobst, Pocklington, and Weidel. Pocklington's careful researches on the microscopical structure of drugs will some day be turned to better account than they have been yet. J. R. Jackson continues his acceptable notes on such of the vegetable materia medica whose history requires elucidating, and E. M. Holmes has laid us under obligation by pointing out sophistications to which belladonna root, cascarilla bark, and arnica root are subject. The readers of this Journal will be familiar with the labours of Hanbury and Sydney Plowman on N-gai camphor, and with the supplementary work of Flückiger on camphors generally. One of the most important and interesting discoveries in pharmaceutical chemistry is the artificial formation of vanillin by Tiemann and Haarmann. This discovery was announced nearly twelve months ago, and works for carrying on the manufacture of vanillin from coniferin have been established for some time in Germany. When may we expect to hear of this artificial vanillin in commerce? And thus we might go on until we had almost reproduced the editor's introductory chapter of sixteen pages, which we have no intention of doing. Those who have the 'Year-Book' may read it and the introduction for themselves, and those who have it not should procure it for the purpose of doing so. The most obvious way of obtaining a personal interest in the 'Year-Book' is by joining the Conference, as some four hundred gentlemen have done since the appearance of the volume for 1873. We believe the Conference now numbers nearly 2,400 subscribing members. The Transactions portion of the 'Year-Book' is edited by the indefatigable London Secretary of the Conference; to say this is to say that it is done as well as can be. One of the most interesting portions of the report of the Executive Committee is that which relates to the Bell and Hills Research and Library Fund. From this it appears that two grants of £10 each and one of £5 have been made to assist in the prosecution of original research. Each of the three gentlemen who receive these grants has contributed at least one paper to the London meeting, which also had the good fortune to receive communications from two foreign members, Dr. de Vrij (who was present at the meeting) and Professor Flückiger, as well as from many gentlemen at home whose names are familiar to all readers of this Journal.

PROCEEDINGS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION AT THE TWENTY-SECOND ANNUAL MEETING, HELD IN LOUISVILLE, KY., SEPTEMBER, 1874. Also the Constitution and Roll of Members. Philadelphia: Sherman and Co. 1875.

Though this is a more imposing volume than the 'Year-Book,' it cannot be said to contain a much greater amount of matter in its 658 pages. The paper is very thick, and the bulk of the type very large, so that the average page-contents of the two works are about equal It may be interesting to give a short description of the contents of the volume, and the way in which they are arranged, especially as the arrangement hitherto followed is departed from in the present instance. Let it first be understood that the Association comprises fifteen committees in addition to the executive, which are either standing, special, or permanent. It is the duty of these committees to prepare reports to be laid before the Association at its annual meeting; and the reception of these reports, together with one on the Progress of Pharmacy, and their discussion, is the main business of the meeting. In previous years, the minutes of the Association meetings have formed the first part of the volume, followed by the reports above mentioned and essays by individual members, printed in full. This arrangement delayed the appearance of the book till someting like six months after the meeting, the secretary being obliged to get the minutes in type before he could proceed with the printing of the reports and essays. Assuming that these reports, etc., are *ready* at the time of the meeting, the secretary hopes that by placing them at the commencement of the volume, he may print off almost immediately, and be able to distribute the 'Proceedings' after a delay of only two to three months. It will be seen that this new arrangement is similar to that which is followed in our own 'Year-book,' for the report on the Progress of Pharmacy, and the reports of committees on adulteration, exhibition of specimens, legislation, Pharmacopœia, unofficinal formulæ, etc., of the 'Proceedings,' comprise all the subjects treated of in the 'Year-Book' proper, and a few more. The editor of the 'Year-Book' is, however, not assumed to have the MS. ready for the annual meeting of the conference.

The report on the progress of pharmacy occupies 277 pages, and is divided into the sections: 1. *General Subjects;* 2. *Pharmacy;* 3. *Materia Medica,* I. *Vegetable,* II. *Animal;* 4. *Inorganic Chemistry;* 5. *Organic Chemistry;* 6. *Necrology;* 7. *Bibliography.* It seems to us that the first section is capable of ready absorption by the remaining ones, except perhaps a few remarks in it on the Status of Pharmacy, wherein the opinions of various writers are collated and compared. The section on pharmacy includes notices of apparatus illustrated by wood engravings, eminently useful to the practical pharmacist; notices of processes and formulæ extracted from scientific journals generally. The Materia Medica are noticed under their respective natural orders. Neither here nor elsewhere in the volume do we find the slightest reference to Hesse's work on the cinchona alkaloids—a capital omission. The section on bibliography is merely a list of works on chemistry, pharmacy, and materia medica which have appeared during the year.

The special and volunteer essays (twenty-six in number), by various members of the Association, form an important feature of the volume. In an "Essay on Granular Effervescent Preparations," Mr. R. V. Mattison severely handles the English manufacturers of citrate of magnesia, and felicitates his American brethren on the conscientiousness of the home makers. A "Report on the Active Principles of the officinal Veratrums," by C. L. Mitchell, contains an exhaustive botanical, chemical, and physiological study of *V. viride*, *V. album*, and *V. sabadilla.*

We entertain a very high opinion of the work performed by the American Pharmaceutical Association as displayed in their 'Proceedings,' but (and the comparison is irresistibly suggested by the simultaneous appearance of the two volumes) we prefer the simpler arrangement adopted in the 'Year-Book,' and are inclined to think that the general style of the abstracts which appear in the latter is superior to that of the corresponding part of the former; the abstracts themselves are fuller and more complete, and likely to prove more useful.

NOTE-BOOK OF MATERIA MEDICA, PHARMACOLOGY, AND THERAPEUTICS. By R. E. SCORESBY JACKSON, M.D., F.R.S.E., etc. Third Edition, Revised, Enlarged, and Brought Down to the Latest Date, by Dr. ANGUS MACDONALD, M.A., F.R.S.E., etc. Edinburgh, Maclachlan and Stewart. 1875.

The appreciation of this well-known work by the medical and pharmaceutical public is sufficiently evinced by the appearance in so short a time of a third edition. Since the appearance of the last one the Supplement to the British Pharmacopœia has been issued, and it appears to have been chiefly with a view to including the new official articles and useful notes thereupon, that the present edition has been revised. In this sense, it certainly is brought down to the present date, and the notes upon the Additions to the Pharmacopœia fully bear out the character of the work, being thoroughly practical, and clearly and concisely written. The work does not pretend to be an exhaustive treatise, but was originally compiled "to relieve the student from much of the mechanical labour of taking notes, while suggesting a more complete investigation of the subject." This office it admirably fulfils, and we envy the student who could take such notes as are herein given, in as few words.

We notice, however, that the current literature upon materia medica seems to have been neglected. Thus, no notice is taken of the now well ascertained botanical sources of Turkey rhubarb, pareira brava, santonica, or sumbul; nor is the information upon the active principles of the aconites, aloes, ergot, and senna, etc., brought up to the present date. This is the more to be regretted since the work—from its convenient size, the clear and concise manner in which information is conveyed, the voluminous index, in which doses and official preparations are so conveniently indicated, and the excellent arrangement of the letter-press throughout the work—is the very model of a student's note-book. It may reasonably be hoped that in the next edition the above omissions will be remedied, for, although in its present state the work may give all the information likely to be required of a medical student, it will by no means meet the requirements of candidates for the Major examination of the Pharmaceutical Society.

The student who for the first time turns his attention to the subject of materia medica may get a very good practical knowledge of his subject from this work; but the more advanced student will certainly prefer to turn to the classical treatises of Pereira and Hanbury.

Notes and Queries.

[429]. PERCOLATORS.—I should be glad if some of your numerous correspondents would favour me with their opinions as to the best form of a percolator; whether cylindrical or conical, together with maker's name.—NIL DESPERANDUM.

[430]. LOGWOOD TEST FOR ALUM.—Can anyone oblige by informing me the strength of the "weak tincture of logwood," and "strong solution of ammon. carb." used in Horsley's test for alum in bread, mentioned by Mr. Siebold.

[431]. SILVERING PILLS.—Can any reader give me information as to the best method of rapidly silvering pills in large quantities—say, for instance, the method adopted in silvering *cachou aromatizé?*—M. P. S.

Obituary.

The Pharmaceutical Society has lost another of its oldest supporters in Mr. Samuel Manthorp, Pharmaceutical Chemist, of High Street, Colchester, who died on the 1st of February, at the age of 66. Mr. Manthorp was a Founder of the Pharmaceutical Society, and served it as one of its Local Secretaries during many years.

We also regret to have to record the death on the 28th February, 1875, from pneumonia, of Mr. Paul William Gibbs Gordelier, Pharmaceutical Chemist, of Sittingbourne, Kent, in his 75th year. Mr. Gordelier became connected with the Pharmaceutical Society in January, 1842, and although he did not take any prominent part in the management of its affairs, embraced every opportunity of showing his sympathy with its objects.

Notice has also been received of the death of the following:—

On the 17th January, 1875, Mr. John Blackbourn, Chemist and Druggist, of Snargate Street, Dover. Aged 65.

On the 23rd February, 1875. Mr. John Unthank, Chemist and Druggist, of Wakefield. Aged 40.

On the 2nd March, 1875, Mr. Eli Steele, Chemist and Drrggist, of Upper Tean, Staffordshire. Aged 34.

We notice also the announcement of the death, on the 26th February, at the age of 71, of Mr. Nathaniel Jacobson, who for many years carried on the business of a chemists' valuer, in Walbrook.

The following journals have been received:—The 'British Medical Journal,' March 6; the 'Medical Times and Gazette,' March 6; the 'Lancet,' March 6; the 'London Medical Record,' March 6; 'Medical Press and Circular,' March 6; 'Nature,' March 6; 'Chemical News,' March 6; 'Gardeners' Chronicle,' March 6; the 'Grocer,' March 6; 'Journal of the Society of Arts,' March 6; 'Grocery News,' March 6; 'Produce Markets Review,' March 6; 'Practical Magazine,' for March; 'Educational Times,' for March; 'British Journal of Dental Science,' for March; 'Journal of Applied Science,' for March; 'Canadian Pharmaceutical Journal,' for February; 'Tennessee Pharmacal Journal,' for February 20; 'Moniteur Scientifique,' for March; 'Pharmaceutische Zeitung,' for March 6; 'Sanitary Record,' March 6; 'Journal de Pharmacie et de Chimie,' for March; 'Répertoire de Pharmacie,' for March; 'The Garden,' for March 6; 'American Journal of Pharmacy,' for March; 'The Pharmacist,' for February; Pharmaceutische Zeitung f. Russland,' for Feb. 21; 'Archiv der Pharmacie,' for March.

PHARMACY IN IRELAND.

Sir,—I must take exception to your article of the 27th February, inasmuch as you appear to be labouring under a delusion with regard to the different classes connected with pharmacy in Ireland. You speak of chemists and druggists and Irish pharmacists—classes of gentlemen to my knowledge non-existent. Apothecaries we have in this country, and we have druggists, the former being the only recognized body qualified for the dispensing of medicines. They have to undergo a searching examination in "arts" before being articled; after which, in anatomy, physiology, practice of medicine, chemistry, botany, and materia medica; in fact, there is little difference between the requirements of an Irish apothecary and an Irish physician. The druggist's shop, as at present constituted, is a kind of general store, where goods of every description can be purchased, drugs included, but whether the druggist's knowledge thereof would even meet the requirements of the Minor examination I very much question, and I must confess my surprise at the pharmaceutical organ even suggesting that Irish pharmacists should form the nucleus of a Pharmaceutical Society for Ireland. There is certainly no analogy between the pharmacist of England and an Irish druggist in point of qualification, and I see no reason why the latter body of gentlemen should expect to derive more benefit from a Pharmacy Act than the humblest shopkeeper. I feel confident that Sfr Michael Hicks Beach will frame a bill acceptable to the majority of apothecaries, and I am assured by many that it will be acceptable if based upon the same principle as the Pharmaceutical Society of Great Britain. A humble suggestion of mine I trust will not come amiss. Would it not be as well for the country at large if the Apothecaries' Hall, as a medical body, ceased to exist, and turned its attention to pharmacy only? I must apologise, Mr. Editor, for not sending this letter last week. I certainly should have done so had I seen the Journal in time.

CHARLES H. HARTT.

107, *Grafton Street, Dublin.*
March 9, 1875.

Sir,—The subject of pharmacy in Ireland seems likely again to occupy the attention of Parliament, and, as the subject has now been dicussed for some years, it does appear to me that something ought to be done. The chemists and druggists of Ireland are crying out for a separate society on the plan of the English Society; this may at first sight look feasible enough, but there are difficulties in the way. In the first place, where are the funds to come from? As the English Society was always self-supporting, it is not likely that Government will give any assistance in that line. The only plan appears to me to be an extension of the English Pharmacy Act, with such modifications as may be necessary. In the first place, I would suggest that all licentiate apothecaries keeping open shop should be placed on the Register as pharmaceutical chemists. Secondly that all chemists and druggists should be eligible to become members on passing a modified examination, and that all assistants may become associates on passing a similar examination. The council of the Society should be enlarged to admit members residing in Ireland to take part in the proceedings of the Society as the Scotch members now do. A branch to be established in Dublin to conduct examinations, etc. The said branch to be supplied with funds from the parent Society.

COMMON SENSE.

Associates and the Library.

Sir,—I feel sure many Associates are thankful to Mr. Schacht for bringing under the notice of the Committee the desirability of extending the right to them of obtaining books directly from the library.

The last Journal tells us that they cannot extend this right. I respectfully suggest that they grant it, a free catalogue, and carriage one way to those subscribing to the Benevolent Fund; probably this would induce some to increase by subscriptions the usefulness of this fund, and certainly many will agree with me that this is most desirable.

According to the decision of the Committee I now have to apply to the nearest pharmaceutical chemist, who is sixteen miles off, to get his recommendation, although I am here in this city, containing a population of 8000.

Edwd. de T. Collins.

Lichfield,
March 9, 1875.

The Objections to a "Square" Man.

Sir,—Allow me in answer to the question of "Veritas" to state what I consider to be the objections entertained by many employers to the so-called "Square" man.

Leaving it to the keen judgment of "Veritas" to decide how far the shop or laboratory by any means can be transformed into a paradise, it is not, as an "Examined Assistant" tells us, that employers disapprove their assistants possessing more knowledge than themselves, but that they should presume to it when they do not possess it. And this is what the "Square" man too frequently does. Having passed his examination and obtained his diploma, he seems to think that he has become an authority on all matters connected with the trade, and when he enters the service of a man unadorned with such honourable distinction he is apt to flaunt his flag in a manner that, to a susceptible nature, is offensive. Filled to the brim with theories which he has had little opportunity of putting in practice, he attempts to do so to the loss and annoyance of his principal, who thus comes to see that scientific attainments are not an unmixed blessing, and that one who is less highly ornamented is perhaps the more useful. I knew of one young man who felt aggrieved because he was not allowed to remove the ordinary labels on bottles containing chemicals and substitute symbols, and from the high platform of his theoretical lore looked down with contemptuous sneer on his ignorant but practical employer. This, I admit, was an extreme form of the madness which afflicts many of those who have just emerged from the examination room.

Of course this sort of thing rights itself bye and bye, and when by brushing with the world the individual finds that after all he is much the same as other men are, and that the possession of a diploma is not a proof of any very rare order of genius, he is all the better for his "Square" studies. Then, again, many men seem to think that having passed their examination they therefore know their business, and they apply for and enter into situations for which they have not yet developed sufficient ability, and their incompetence is frequently erroneously connected with their scientific attainments. The result is, that censure is passed on the whole class to which they belong.

Another objection is, that the "Square" man is so often above his business. With the finest crop of wheat there grow up tares, and the education obtained at Bloomsbury Square is often tinctured with the whimsical ideas of status, etc., which some speakers and writers are so fond of indulging in, preferring the "*videri*" to the "*esse.*" So that the man who previously could do his day's work happily in an apron, now finds it to be a degradation, and instead of an aid to economy a badge of servitude.

Therefore, I think that it is the presumption and high-flown ideas which in so many instances accompany the "scientific knowledge" that prevents the latter from being appreciated.

As "Veritas" says, scientific knowledge must increase the value of an assistant's services, and where it is accompanied with practical ability and business tact cannot fail to obtain that respect it deserves.

J. G. C.

The Finance of Pharmacy.

Sir,—The above subject cannot fail to be interesting (and always so) to the majority of your readers, and as you do not announce that the present discussion is closed, I venture, with all due submission to the value of your space, to offer thereon a few remarks. I cannot but think that those who have written in opposition to the theory or statement of "Veritas" have altogether overlooked the conditions he has laid down for the attainment of the very startling result he has unfolded to our view. Referring to the young man who, having a small sum to commence with, is, in due course, to become the possessor of £10,000, and to retire on £500 or £1,000 per annum, he says :—

1. He must bear "a banner with a strange device;" strange, I suppose, in the sense that it is not familiar to us.
2. He must be a man of business. This is a *sine quâ non.*
3. He must exercise the most rigid economy.
4. He must possess untiring industry and indomitable perseverance.

Good. But are these *all* the conditions which are necessary for the achievement of the desired end? I think not, and, therefore, I venture to add the following :—

5. He (the young man in question) must possess a sound physical constitution, and live in the enjoyment of good health. A man cannot work *con amore,* however competent he may be, if he is weak or ill.
6. He must be in a position to command custom. It is evident he could not take money if there were no money to be taken.
7. He must be free from the burden of an extravagant or irrepressible wife. Few men could survive this infliction long, though it may be no excess of gallantry to say so.
8. He must have no "poor relations" to maintain. If his income went to his relatives where would be his compound interest? And finally and lastly :—
9. When he has secured his nett yearly balance he must invest it with safety and profit.

Now, given all these conditions, and cause and effect will be immediately apparent. Herein the position of "Veritas" will be completely unassailable. But, then, as I imagine, it is not so much a question of *possibilities* (else where should we stop?), as of *probabilities.* Taking men *as they are,* and the trade *as is is,* and what are the financial prospects of the pharmaceutical calling? The answer to this will be best found in *facts,* and in this instance, facts clearly show us that whilst the great majority are striving day after day to secure a living and pay their way, it falls to the lot of the comparatively few to carry the Excelsior Banner, and to attain that position which all so eagerly desire, but which, in its realization, falls so short of the earthly paradise we, in our too confident estimates and anticipations, imagine it to be. If, then, the young chemist, with a small sum to commence with, aims to become the possessor of £10,000 and upwards, he must conform to the conditions which the attainment of that result so undeniably imposes. Are, then, these conditions more exacting in pharmacy than in any other calling, whether profession or trade? If so, the question of personal fitness and ability acquires considerable importance as influencing or determining the result in each particular case. That great things may be accomplished, even in the drug trade, is impossible to deny; but herein, perhaps, it is to be remembered as specially applicable the trite aphorism, He "who would be free *himself* must strike the blow." And to those who have not achieved this success, who, in fact, are not so gifted, or so specially circumstanced, whilst they observe here and there in the far heights the waving of the envied and glittering Banner, they need only glance along the plain to find abundant and mayhap consoling illustration of the equally forcible truism, "The race is not to the swift, nor the battle to the strong, neither yet bread to the wise, nor yet riches to men of understanding, nor yet favour to men of skill; but time and chance happeneth to them all."

February 23, 1875.

Milk of Sulphur.

Sir,—While cordially agreeing with your criticism on the remarks made by the magistrate, in the "Morning Tonic" case, I must take exception to your view of the "Milk of Sulphur" question.

On reading the report in your columns, it was patent to me that the medical analyst of Leeds had never been a druggist, or he would have been better able to stand the trenchant cross-examination of Mr. Simpson and explode his sophistry. He would have been able to tell him that for some years the term "Lac Sulphuris" has been generally ignored by wholesale druggists;—that in their lists is printed "Sulph. Præcipitatum," followed by "Sulph. Præcip. Pur."—a tacit admission that the former is impure; or they print "Sulph. Præcip. Pur." followed by "Sulph. Præcip. Sec.," while some plainly state "Sulph. Præcip. containing Sulphate of Lime." He could have told them, that, in the list of Messrs. Howards and Sons, of Stratford, is printed "Sulph. Præcipitatum Ver. (delicate colour and very pure)," and that if Messrs. Howards and Sons were applied to to supply a "lac sulphuris" of half the value, they would refer the applicant to houses of less high character than themselves. I observe that in some wholesale druggists' lists only "Sulph. Præc. Pur." is quoted, Barron, Squire and Co.'s, for instance. I never heard of a medical man prescribing sulphate of lime as a medicine, either alone or combined with sulphur, or anything else; and if perchance a medical man were to prescribe "lac sulphuris," he would certainly not mean a preparation containing an equal moiety of calcis sulph.; nor would any druggist having regard for the purity of the chemicals he dispensed prepare the prescription with such an article.

The state of the case is this. If the children of my Lord Knows-Who, of Grosvenor Square, require some "milk of sulphur," it will probably be got from the adjacent Duke Street, and sulph. præcip. pur. will be assuredly supplied for their aristocratic stomachs. But, if the children of my lord's gamekeeper, resident at Stokum-cum-Pogis, need some, and the chemist and druggist of that enlightened village be the purveyor, their plebeian insides will almost as certainly be dosed with stuff containing not less than 50 per cent. of sulphate of lime. Their father will doubtless not pay nearly so high a price for their dose as his lordship will be charged for that for his children in his Christmas account, but that would be but a sorry consolation to him or them if they understood the state of the case.

I hold that the "lac sulphuris" of commerce is as much an adulteration as if anyone were to purchase sulph. præcip. pur., and afterwards mix it with sulphate of lime. It is all moonshine saying that the public object to purchasing the genuine article. I have not for some years sold any other, and I am quite sure that it is smooth and impalpable, and as little disagreeable as any impure can be. When I kept both, nine persons out of ten—I had almost said ninety-nine out of a hundred—if asked, would elect to be supplied with the "best;" I was always ready to explain that one was pure and the other very impure. What druggist other than a simpleton, when supplying some for his own family, would give the impure article?

Again, it is sheer disingenuousness to pretend that "milk of sulphur" means one thing, and "precipitated sulphur" another. If it were so Messrs. Howards would not require to manufacture hardly one-thousandth part the quantity they do, for its use would be limited to prescriptions, in which it seldom appears. I never was asked by a customer (other than a surgeon) for "precipitated sulphur." Will anyone contend that in supplying it for "milk of sulphur" I have been guilty of substituting one article for another?

The selling of such an article as the one in question has long been a disgrace to the drug trade—quite as bad as a grocer knowingly selling a mixture of one half ground rice or pea-meal as pepper—and it is to be hoped that the publication of the recent proceedings at Leeds, and thorough ventilation of the subject, will have the effect of putting an end to it.

I thoroughly sympathize with the scammony victim, but I am amazed that anyone if asked to supply scammony across the counter should return other answer than an emphatic "got none"—accompanied by an unmistakable look to match.

I purposely refrained from sending you this letter until after the decision in Mr. Harrison's case had been given. I think he has much reason to congratulate himself in having only been mulcted in a nominal fine and no costs.

On some future occasion I may address you respecting other articles pretty generally sold by druggists in a sophisticated state; and I could say something on the proposed Bill published in your last issue, but the length my letter has already reached restrains me.

Robt. Chipperfield.

Southampton, Feb. 22, 1875.

Carbolic Acid.

Sir,—In the last number of your Journal a letter is published by Mr. Bickerdike, in which he says:—

"I state that the boiling point of pure phenol is 184° C., whilst Mr. Lowe states it to be 182°; and further adds, that these two degrees of boiling point indicate a material impurity in the acid boiling at 184° C. In another place Mr. Lowe refers to Messrs. Dale and Schorlemmer as trustworthy authorities, and I should be equally willing to accept their statements on a scientific point. In the *Journal of the Chemical Society* for 1873, p. 441, these gentlemen, in speaking of their experiments on aurin, say, 'We therefore prepared the colouring matter from pure phenol boiling quite constantly at 184° C., and melting at 42°, a large quantity of which was kindly placed at our disposal by Messrs. Chas. Lowe and Co.'"

This discrepancy between Mr. Lowe's statement and ours is easily explained, being simply due to a difference in the thermometers. That which we used had previously been repeatedly exposed to a high temperature. Now it is well known that under these conditions the bulb always shrinks a little, and consequently the thermometer indicates the temperature a little too high. Although being aware of this we did not correct our number, because it was not our intention to make an exact determination of the boiling point of phenol, the fact that it boiled quite constantly from the first to the last drop was sufficient to show that it was a pure compound. Since that time I have again determined the boiling point of the very same sample of phenol from which our aurin was prepared. The thermometer which I used was expressly constructed for the determination of high boiling points. It has a very short scale, beginning at 90° C., the two fundamental points being the boiling point of water and that of pure naphthalene, which Dr. H. Geissler, who makes these instruments, has found to boil constantly at 217°. These thermometers are exceedingly convenient, because the whole column of mercury can be immersed in the vapour, and thus no corrections are required, which always are only more or less approximate. I obtained the following results, the height of the barometer being 725 m m.:—

Water	100°
Phenol	181.5°
Napthalene	217°

C. Schorlemmer.

The Owens College,
Manchester, March 1, 1875.

Synonyms.

Sir,—It was with much pleasure I read in your last issue Mr. Haselden's communication on the above subject. I quite agree with him in thinking that this useful addition might be more extensive in the present Pharmacopœia with advantage.

It is a matter in which I myself have been interested since my first introduction to pharmacy, and I at one time copied and arranged alphabetically from Redwood's 'Gray's Supplement' the whole of its contents of synonyms, and found the list one of the most useful pocket companions I ever possessed.

The above mentioned work is the best I ever had access to for giving obsolete terms connected with chemicals and drugs, but even in it the idea is not extended sufficiently.

What I have often wished for has been a good "Book of Synonyms for the use of Chemists and Druggists," and if one was compiled by some competent man I am sure it would have a ready sale, be a great help to students, and I believe also it would be a preventive of mistakes occasionally. What apprentice, having entered the business within the last three or four years, if asked by a customer, would be able to give half a dozen of the following without first scratching his head and then going to the principal for advice?—

Turner's Cerate,	Lenitive Electuary,
Mindererus Spirit,	Rufus Pills,
Hoffman's Anodyne,	Griffiths' Mixture,
Jesuits' Bark,	Flowers of Zinc,
Yellow Basilicon,	Liver of Sulphur,
Colophony,	etc., etc.

Or, if he had a prescription or recipe put before him with either of the following ordered, I think he would require a little assistance:—

Tinct. Thebaicæ,	Ext. Saturni,
,, Amaræ,	Elixir Proprietatis,
,, Opii Camphorata,	Sal Polychrestum,
Infus. Diosmæ,	,, Enixum,
Ext. Cynosbati,	etc., etc.

Trusting this matter will be followed up by others, I am, etc.,

J. T. C.

Manchester, March 3, 1875.

Sir,—The letter of Mr. Haselden on synonyms is deserving of much consideration, especially by Professor Redwood, should he contemplate another edition of 'Gray's Supplement.'

Our apprentices and assistants of the present day may glean much information from the older editions; some of the old formulæ would explain the derivation of many names which, as Mr. Haselden remarks, are far from being obsolete.

How many of our young students would be able readily to dispense the following prescription, which was often written thirty to forty years ago, and not unfrequently is presented to me now:—

℞ Sal Cathartic. Amara . . . . ℥iss.
P. Coccinella . . . . gr. x.
Sal Nitri . . . . ʒj
M.
Extr. Saturni . . . . ℥ss.

The oft-recurring question, What is cinnabar of antimony, would be solved, also the significance in the name of so many "Vitriols."

Geo. Cocking.

Ludlow, March 4, 1875.

Copies of Prescriptions.

Sir,—I should be glad of the opinion of experienced pharmacists as to the propriety of making some charge for copies of prescriptions. It is a common thing for a patient to lose his prescription and then apply to the dispenser for a copy of the same, expecting it gratis.

The point has already been brought before us in the Journal, but I do not remember that any pharmacist of known reputation contributed his opinion, or that anyone informed us that he had adopted the system. If it is adopted by some, I should be glad to learn what charge is made.

"Fideliter Peragimus Artem."

February 25, 1875.

"Donor Unknown."

Sir,—In the list of donations to the library in last week's Journal is one, "'Nouvelles Recherches sur les Liquides Pathologiques de la Cavité Pleurale' (donor unknown)." Will you allow me to state that the author and donor of that pamphlet is Dr. C. Méhu, Pharmacien de l'Hôpital Necker, Paris. He was the delegate of France, and the able exponent of the views of French pharmacists, at the St. Petersburg Congress. That these international courtesies should be duly acknowledged is the object of this letter.

Thomas Greenish.

Caution.—Mr. J. Farmer, of Putney, informs us that he has just been questioned by a lady on the difference between his Frederickshall Water and some which she had bought from a soda water cart in the street, the one at 18*s.* and the other at 8*s.* per dozen quart bottles.

G. Cathcart.—Assuming that Dr. Kirby would be willing to supply the information, your best course would be to apply to him directly.

"*Quærens.*"—The provisions of the 17th section of the Pharmacy Act do not apply to articles to be exported from Great Britain by wholesale dealers, nor to sales by wholesale to retail dealers in the ordinary course of wholesale dealing, nor do any of the provisions of this section apply to any medicine supplied by a legally qualified apothecary to his patient, nor to any article when forming part of the ingredients of any medicine dispensed by a person registered under this Act; provided such medicine be labelled in the manner aforesaid, with the name and address of the seller, and the ingredients thereof be entered, with the name of the person to whom it is sold or delivered, in a book to be kept by the seller for that purpose.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

MISTURÆ.

BY CHARLES SYMES, PH.D.

For some years past new remedies have been introduced much more rapidly than existing ones have become obsolete, and modified forms of these latter have also become numerous, yet room still remains for considerable improvement in the already voluminous list.

There are in the Pharmacopœia certain preparations known as mixtures, to which, it seems to me, some additions might be made with advantage.

Mist. gentianæ is largely prescribed, and with *some modifications in manipulating its process* is a good and creditable preparation. I will not here take exception to its being classed amongst the mixtures, although some grounds exist for so doing. It is in itself a type of a special formula put on its trial and approved by the profession. The question now arises, therefore, What other substances should be brought under the same category?

Anyone who has examined the marc left from infusion, fluid extract, or even decoction of cinchona will be aware that a large portion of the alkaloids remain undissolved, so that the preparations do not really represent the amount of bark from which they are prepared. The United States' Pharmacopœia surmounts this difficulty by the addition of aromatic sulphuric acid to the water used for exhaustion; the acid being added only in small quantity and partially combining with the lime present in the bark, the amount remaining free in the resultant liquid might be considered unimportant. Now, I would suggest, as an elegant, efficient, and not disagreeable preparation, mistura cinchonæ prepared thus:—

Yellow Bark, in coarse powder	of each	℥ss.
Powd. Liquorice Root		
Dilute Sulphuric Acid		♏ 50.
Distilled Water		Oss.

Moisten the mixed powders with the acid liquor, transfer to a percolator, pour on the remainder of the fluid, and when it ceases to drop, continue the percolation with water till 8 ounces have been obtained; add to the percolate 2 ounces of proof spirit, and the result will be a pale sherry coloured liquid, perfectly bright, containing much more of the alkaloids than the ordinary infusion, and yet with the bitterness to some extent covered by the liquorice. It keeps well for some weeks at least.

Calumba is a bitter very frequently prescribed, but its infusion has a somewhat musty and disagreeable smell and taste, and it does not keep more than a few days. This is a case in which we might with advantage produce a mist. calumbæ free from these undesirable characters. It would be necessary to avoid adding anything possessing astringent matter, as columba is so frequently prescribed with iron. This might be accomplished as follows:—

Take of—

Calumba Root, in coarse powder	½ oz.
Water	8 ozs.

Macerate two hours.

Bruised Cardamom Seeds	20 grs.
Proof Spirit	2 ozs.

Macerate for the same period, strain, and mix the liquors.

This small quantity of cardamoms gives a pleasant aromatic taste and odour to the liquid; it keeps well.

Mist. rhei co. in which the taste of rhubarb is somewhat masked, would, I think, be prescribed by many practitioners, if a good formula were produced; the following, perhaps, admits of improvement, but it possesses the qualities mentioned as desirable:—

Rhubarb Root, in coarse powder	150 grs.
Boiling Water	9 ozs.

Macerate for two hours, strain and produce 8½ ozs.

Powdered Pimento	of each	50 grs.
,, Coriander		
Proof Spirit		1½ ozs.
Spirit of Chloroform		1 drachm.

Macerate two hours, and filter into the strained infusion.

This is a cordial aperient, elegant, and not disagreeable; it keeps well.

More examples might be added, but they are at present unnecessary. In any future edition of the Pharmacopœia, these or similar formulæ might be added with advantage; their adoption by the medical profession is highly probable, and they would in many instances replace the infusions of the same substances.

This weak spirituous form of preparation is far from desirable for a very large number of vegetable substances, but I have endeavoured to select those in which it is suitable, and to which no valid exception can be taken.

Liverpool, February 26, 1875.

ACTIVE PRINCIPLES OF FOXGLOVE.*

BY PROFESSOR SCHMIEDEBERG, OF STRASSBURG.

The author has prepared a new, well-defined, crystallizable principle, *Digitoxin*, from the leaves of *Digitalis purpurea*, and exactly investigated the constituents of commercial "digitalin," as obtained from seeds of the same plant.

As to *Digitoxin*, Schmiedeberg completely exhausted with water the leaves previously dried and powdered, and then extracted them repeatedly with dilute alcohol, 50 per cent.; the tincture thus obtained was then mixed with basic acetate of lead as long as it produced a precipitate. The latter being separated, the filtered liquid was concentrated and the deposit now formed, after some days, removed from the aqueous liquid. It was then washed with a dilute solution of carbonate of sodium, by which a yellow matter (*chrysophan?*) was partly removed. The substance was then dried and yielded to chloroform a brownish mass, which after the chloroform had been driven off, was purified by benzin. This liquid dissolved the remainder of the yellow or orange matter, and a little fat, leaving crude digitoxin, which is to be purified by recrystallization from warm alcohol, 80 per cent., adding a little charcoal. This purification still yields yellowish crystals, which ought to be washed again with carbonate of sodium, ether or benzin, and then recrystallized from warm absolute alcohol, containing a little chloroform. This process, however, will only afford colourless crystals provided it be so performed as to cause the separation of digitoxin on account of the cooling of the solution, not by the evaporation of the solvent. If the liquid is instead allowed to evaporate it will soon assume a darker coloration. In the way just pointed out, perfectly colourless scales or needle-shaped crystals of pure digitoxin are at length formed, the yield being not more considerable than about *one* part from 10,000 of dried leaves.

*Abstracted from the author's paper in 'Archiv' fü experiment. Pathol. und Pharmakol., III. (1874) 16.'

Digitoxin is insoluble in water, to which it does not even impart its intensely bitter taste as displayed in alcoholic solution. It is likewise insoluble in benzin or bisulphide of carbon, very sparingly soluble in ether, more abundantly so in chloroform, the latter liquid however acting but very slowly on digitoxin. Its best solvent is alcohol, either cold or warm. The composition of digitoxin answers to the formula, $C_{31}H_{33}O_7$.

Digitoxin warmed with concentrated hydrochloric acid assumes a yellow or greenish hue, the same which is commonly attributed to commercial "digitalin." Digitoxin is not a saccharogenous matter; in alcoholic solution it is decomposed by dilute acids,* and then affords *Toxiresin*, an uncrystallizable, yellowish substance, which may easily by separated on account of its ready solubility in ether; it appears to be produced also if digitoxin is maintained for some time in the state of fusion at about 240° C. Toxiresin proved to be a very powerful poison, acting energetically on the heart and muscles of frogs. The very specific action of foxglove is due—*not* exclusively—to digitoxin; it is so highly poisonous that Schmiedeberg thinks it not at all fit for medicinal use, which might rather be confined to other constituents of foxglove, as, for instance, to those described further on under the names of digitalin and digitalein. The latter, however, are of more difficult extraction than digitoxin.

The preparation of digitoxin is similar to that of *Nativelle's* crystallized "digitalin;" † the former as well as paradigitogenin (of Schmiedeberg) are largely found in Nativelle's digitalin.

Foxglove growing abundantly in Alsace, there is at Strassburg a firm, Messrs. Henn and Kittler, making digitalin from seeds on a somewhat large scale. They exhaust the seeds with alcohol, fifty per cent., distil off the alcohol in a vacuum apparatus, purify the liquid by means of acetate of lead, and add tannic acid. From the precipitate now formed and immediately dried "digitalin" is separated by means of oxide of zinc. It is a whitish powder, almost completely soluble in water, and acting very energetically.

This commercial digitalin chiefly furnished the materials of Schmiedeberg's researches on the principles afforded by the *seeds of foxglove*. Among them three substances are directly obtainable, being no doubt contained in the seed itself; whereas, five other substances are artificially derived from the former, viz.:—

I.—*Digitonin*, an amorphous body, soluble in water; not in cold alcohol, nor in ether, benzol, or chloroform. It yields by decomposition sugar, and gradually the following derivatives:—

I[a]. Digitoresin.
I[b]. Digitoneïn.
I[c]. Digitogenin.
I[d]. Paradigitogenin.

II.—*Digitalin*; it forms roundish, not crystalline, tufts, sparingly soluble in cold water, ether, or chloroform; abundantly in alcohol, or in alcohol containing chloroform. Digitalin is likewise dissolved by even dilute acetic acid as well as by boiling water; it may be split up in sugar, and—

II[a]. Digitaliresin, which again may be resolved into substances not yet more exactly examined.

III.—*Digitaleïn*, a yellowish substance, affording with water frothing solutions like digitonin, yet differing from it by being soluble in chloroform. The product it yields by dilute boiling acids appears to agree with digitaliresin.

I. *Digitonin.*

Commercial digitalin, as alluded to, is moistened with absolute alcohol, and then treated with a mixture of equal volumes of alcohol and chloroform, which will dissolve the most part of "digitalin." The filtered liquid, on addition of ether, yields digitonin, which is to be subsequently dissolved by warm alcohol, purified by charcoal and again precipitated by ether. Digitonin may also be prepared by mixing a concentrated aqueous solution of "digitalin" with baryta, when a precipitate is thrown down, from which carbonate of barium may be separated by means of carbonic acid. Digitonin then remains in the liquid, which is to be cautiously concentrated, diluted by alcohol, and then mixed with a little ether in order to precipitate first some impure digitonin. This being removed and more ether added, nearly pure digitonin makes its appearance; it is perfectly purified by repeating this treatment, which, however, will unavoidably cause a considerable loss of digitonin. Its aqueous solution partakes of the frothing quality of solutions of *saponin*; and, in fact, digitonin and saponin are very closely allied. Schmiedeberg assigns to digitonin the formula $C_{31}H_{52}O_{17}$, Rochleder's formula of saponin being $C_{32}H_{54}O_{18}$.

Digitonin turns red by boiling with dilute sulphuric acid, not so saponin. The former then yields a flocculent matter, consisting of *digitoresin* and *digitoneïn*; digitoresin may easily be removed by means of ether. Digitoneïn is soluble in boiling alcohol, or in alcohol containing chloroform, and is separated from these solutions by ether in form of white tufts, devoid of crystalline structure. Digitoresin, as well as digitoneïn, is further resolvable into sugar and substances which remain to be examined. The product thus afforded by digitoneïn yields, with concentrated sulphuric acid, a brown liquid, displaying in sunshine a magnificent green fluorescence. Lastly, digitoresin and digitoneïn have also been observed in an aqueous solution of digitonin, mixed with an aqueous infusion of foxglove leaves, the whole liquid being kept for some months in a temperature of 35°, when a slow fermentation took place.

A crystallized substance, *digitogenin*, is afforded if either digitoresin or digitoneïn in alcoholic solution is boiled for a day or two with dilute sulphuric or hydrochloric acid. The alcohol is removed by distillation, the yellow residue washed with water and crystallized from hot alcohol. The long, colourless, needle-shaped crystals of digitogenin are abundantly soluble in chloroform, but little in ether. They are not coloured by cold concentrated sulphuric acid, but turn yellow by warming, and then display the same green fluorescence as the above-mentioned derivative of digitoneïn.

On exposing to slow fermentation a solution of digitonin there is found a considerable deposit from which *paradigitogenin* may be extracted by chloroform; it is likewise crystallizable and very closely allied to digitogenin. Yet paradigitogenin, when

* For this reason all the liquids or precipitates to be worked upon, in order to get digitoxin, ought to be kept *neutral with the utmost care.*

† See *Flückiger and Hanbury*, 'Pharmacographia,' 423.—Another crystallized substance, from seeds, mentioned by those authors, l.c., 424, has not been examined by Schmiedeberg.

moistened with cold concentrated sulphuric acid, assumes a reddish-brown hue; that substance is also readily formed by heating commercial "digitalin" with water to about 210° or 220° C. Paradigitogenin has been proved to be present to some extent in Nativelle's digitalin; it agrees, perhaps, with the "digitalose" of Homolle and Quevenne.

II. *Digitalin.*

This appellation has been applied by Schmiedeberg to a very well-defined substance, which he removed from commercial digitalin by mixture of 1 volume of ether and 3 volumes of alcohol. The liquid is repeatedly shaken with small quantities of water, which will dissolve both *digitalin* and digitaleïn, although pure digitalin, if not accompanied by other constituents of foxglove, would not dissolve in water. From the above liquid the ether is distilled off, and water is added, and then if the liquid be concentrated by gently warming it, a flocculent whitish or yellowish mass of Schmiedeberg's digitalin is obtained. The same may also be got from the ethereal solutions, which had furnished digitonin, as above said. Crude digitalin is contaminated with a yellow matter, probably *chrysophan*. This is removed by using a weak solution of carbonate of sodium; the digitalin is then washed with chloroform, dissolved in warm dilute alcohol, from which it separates on cooling, in a few days. It is not convenient to evaporate the solution of digitalin, because it would quickly darken, even in presence of charcoal. Digitalin forms soft, colourless, small grains, agreeing in composition with the formula $C_5H_8O_2$; the solvents for this substance are alcohol, alcohol containing chloroform, and dilute acetic acid; whereas it is but sparingly dissolved by ether or chloroform, still less by water, even when boiling. This well-defined digitalin possesses in a high degree the action of foxglove on the heart; it is the prominent constituent of several kinds of commercial digitalin, especially that of Homolle and Quevenne.

Schmiedeberg's digitalin dissolves in cold concentrated sulphuric acid without assuming any coloration; it strikes yellow or yellowish-green when warmed, and beautifully red if a little bromide of potassium be added. At the same time sugar and *digitaliresin* are produced; the latter is, like its mother substance, a very powerful poison. Yet digitaliresin itself is further capable of being resolved into sugar and another derivative, which is devoid of any active virtue. Digitaliresin is, on the whole, nearly allied to digitoresin.

III. *Digitaleïn.*

In order to get this substance, the liquid, which had already yielded digitalin, is evaporated *in vacuo*, the residue dried over sulphuric acid and dissolved in absolute alcohol. On addition of a little ether, impure digitaleïn separates, the liquid at the same time becomes perfectly clear. On further addition of ether, purer digitaleïn is precipitated. The redissolution and precipitation is to be repeated until the digitaleïn turns no longer red with boiling concentrated hydrochloric acid, but only yellowish. It has, nevertheless, not yet been possible to deprive it entirely of a yellowish hue. In other respects digitaleïn agrees with digitalin, but the former is abundantly soluble in water, and this solution is frothing like that of digitonin. Digitaleïn is, on the other hand, also readily dissolved by absolute alcohol, while digitonin is not so.

ARTIFICIAL SALT BATHS (SOOI BÄDER).

BY DR. G. SIEGMUND.*

The object of this paper, by Dr. G. Siegmund, published in the *Berliner Klinische Wochenschrift*, January 11 and 18, 1875, is not to explain what operation the various ingredients of salt springs have on the organism, but to show how the use of salt baths may be introduced into every house. Salt springs, which are obtained from various sources (from natural wells, from borings, from rocks, by letting in water to dissolve the salt they contain) not only differ from each other very much in their degree of concentration, but they often vary in the amount of their mineral ingredients in the same source. Natural springs, and those got by boring may, according to the nature of the rock which is superimposed, be greatly influenced by the daily rainfall. Such natural dilutions are easily made up for by adding a suitable amount of salt; and it would not be necessary to allude to this, if such deficiencies were always attended to in bathing establishments. Whoever has often been present at the filling of baths in such places, must know how little attention is paid to the degree of concentration. But the principle should be laid down, that the degree of concentration ordered by the medical man should be as much attended to as the degree of temperature. The quantity of salts present in the waters of the most visited baths, varies from about 1·5 to 31 per cent. (Rheinfelden) or to the strength almost of a saturated solution; and if we consider only the amount of chloride of sodium, those having less than 1 per cent. are scarcely worth counting, while the stronger ones reach 20 and even over 30 per cent.

But we must guard against considering the strength of the natural water as identical with the strength of the bath, and here attention must be called to a fault from which few monographs are free, not even Dr. Niebergall's careful tables in Valentiner's 'Balneology,' 1873. Handbooks, and special accounts of baths, give analyses of salt springs; but as there are but few salt springs whose waters are used in their natural state, most salt waters are, in fact, constantly either strengthened or weakened, according to their degree of concentration. It is not enough to tell us how much is added to a bath unless we are told what the whole quantity of water in it is. The quantity of water added to reduce a concentrated solution, and the quantity of a weak salt water to which a certain amount of the concentrated solution is added, must both be known. But from neglect of this, we generally are ignorant of the real strength of a bath, and in many places can only ascertain it by the use of a hydrometer. We imagine a strongly concentrated fluid when we think of the Ischl spring, containing 24·5 per cent. of salts, and of a bucketful of it containing thirty to thirty-three pounds, and know that one or two bucketsful are added to the bath. But if we reflect that a full bath requires about fifteen bucketsful of water to fill it, we find that the addition of one bucketful only brings the bath water up to the strength of a salt spring of the second degree, and of two buckets to that of one of the third degree; and in Arnstadt, where the natural spring contains from 22 to 25 per cent. of salt, although, according to Niebergall, baths are occasionally prepared of the strength of 8 per cent., yet the usual strength is only for children from 1 to 2 per cent., and for grown-up people 3 per cent.

The actual practice at different baths varies much, and depends much on the abundance or otherwise of the supply of salt. If in Ischl the baths seldom exceed 3 per cent., and in Kösen the baths of nearly 5 per cent. are counted strong and exciting, no one thinks anything of the nearly 5 per cent. water of Colberg. In Salzungen the strength is usually from 3 to 6 per cent., and this is often further fortified by the addition of mother liquor, as it is

* Abridged translation of a paper read before the Berlin Medical Society. Reprinted from the *London Medical Record*.

called. The baths in Rheinfelden are of a strength of 3 to 8 per cent., and in Frankenhausen of 7 to 8 per cent. and more; yet the patients do not complain of excitement, sleeplessness, or of irritation of the skin, or of any other unpleasant effects. We are wont to think only of the chloride of sodium in salt springs; and indeed the other constituents amount to a very small quantity, as is apparent from the following table.

	In 100 parts of water. Total constituents.	Not chloride of sodium.
Rheinfelden	31·8	0·7
Ischl	24·5	0·9
Salzungen	26·5	0·8
Arnstadt	23·7	1·3
Reichenhall	23·3	0·8
Bex	17·0	1·3
Juliushall	6·5	0·4
Elmen	5·3	0·4
Colberg	5·1	0·7
Kösen	4·9	0·5
Sulza	10·7	0·8
Kreuznach (Oranien)	1·7	0·3
Münster am Stein	0·8	0·1
Rehme	4·0	0·8
Nauheim	3·5	0·6
Kissingen (Soolspindel)	1·4	0·3

This table shows sufficiently the immense preponderance of common salt. There are, however, some exceptions to this rule: thus, in the Hubertusbad, the total of mineral ingredients is 2·69 per cent.; of this only 1·49 is chloride of sodium, while 1·16 is chloride of calcium, and in a well in Suderode the chloride of calcium, 1·5 per cent., exceeds the chloride of sodium, 1·1 per cent. In Zaizon, one of the iodine and bromine springs, in 0·27 of mineral ingredients 0·06 is the amount of chloride of sodium, 0·02 of iodide of sodium. Similar exceptions might be adduced, but the general rule of the entire preponderance of chloride of sodium over other constituents remains unaffected. With reference to the occurrence of other salts, there is no uniformity. Besides sulphate of lime, which is rarely absent (and which is of no great therapeutic importance), sulphate of soda and of magnesia occur, but by no means constantly, and only in small quantity.

Passing by iodine and bromine, which do not bear directly on our object, the remaining salts are combinations of chlorine and alkalies. Of these chloride of magnesium is usually present; chloride of lime and chloride of potass are so occasionally.

I must next speak, Dr. Siegmund says, of the practice prevailing almost everywhere of strengthening the baths with the mother liquors.

Here, too, there is no rule as regards the chemical mixture. Iodine and bromine, referred to with much pride in some mother liquors, are entirely wanting in others, and when they are present, what amount of real efficiency do they possess? In the lye of Münster, according to one analysis, we have 0·59 per cent. of bromide of sodium and 0·05 of iodide of sodium; according to another one, we have 0·6 of the bromide without any iodide, while another gives the Theodorshall spring 0·77 of bromide of sodium and 0·0007 of iodide of sodium. We may then have in those two lyes, 0·6 to 0·7 of the bromides and iodides.

Suppose we add, what is counted a large quantity, 10,000 grammes of the lyes to a bath containing 300 litres, we have about sixty grammes of bromine and iodine compounds, or perhaps 0·02 per cent. It may be possible that even with this degree of dilution there may be, in the presence of the other salts of the solution, some slight cutaneous absorption; but we must remember that the above strength is greater than that of the baths usually supplied.

Where bromine and iodine are absent, it is generally the presence of a large amount of chloride of calcium that is characteristic—for instance, in Nauheim 29·97 per cent., in Münster about 25 per cent., in Theodorshall 33·2 per cent.; but in some places chloride of magnesium is in excess in the lye, for instance, 48·6 of chloride of magnesium against 23·9 of calcium in Wittekind, and 24·4 of the former against 17·06 of the latter in Arnstadt. In Salzungen there is 17·2 per cent. of chloride of magnesium and none of calcium, and in Ischl and Rheinfeld the lye is practically only a very rich solution of common salt, with perhaps a tenth of other chlorine compounds which are soluble in the lye.

The great dissimilarity of the composition of the salt springs naturally repeats itself in the lyes. It is out of the question to talk of them as homogeneous fluids; and even if their constituents were well ascertained, and their variations were closely copied in their imitations made at Leopoldshall, yet it is beyond doubt that physicians order lyes quite promiscuously, those of Colberg, Schonebeck, Salzung, Wittekind, as they may be nearest to hand, and that they only use them with more discrimination, perhaps, in the case of those valued for containing iodine or bromine.

We may draw one general conclusion from all this, that we do not act under the guidance of any principle. We do not know what is the special action of the chloride of sodium, or that of the other salts. Our only criterion is the amount of salts; we know that a certain degree of concentration is necessary to produce a certain stimulation of the skin.

As examples of the absolute amount of salts in individual baths, we may further mention that the water of Elmen contains sixty pounds of salts in a bath of thirty cubic feet; that of Salzungen, in the bath (the amount of the water of which is not given), forty to forty-eight pounds; and that of Frankenhausen forty-eight pounds in only 300 litres of water.

We shall next inquire what course has been usually pursued in the preparation of artificial salt baths as compared with natural ones. We make use of sea salt, seldom of chloride of sodium, or of mother lye or its salt, to strengthen the salt baths. But in what quantities do we use them? The quantity of sea salt or of chloride of sodium for a bath is usually set down in handbooks at two to six pounds. The 'Prussian Medical Calendar' of 1874 was the first to say from ten to fifteen pounds. Now the former maximum of six pounds, which even now is counted a considerable quantity, gives in a bath of 300 litres a solution of 1 per cent. An idea may be got of how little conception people had of the real strength of such baths, from the fact that patients in hospitals here when ordered salt baths, usually were ordered not more than six baths, each of which contained 2 lbs. of salt. But the uselessness of the ordinary practice is still more apparent in the case of the mother lyes. It was usual to order 1lb. to 2 lbs. for a child's bath. Usually the lye was selected with reference to the quantity of iodine which it contained; but had one any right to expect important results from so small a quantity? The Kreuznach lye, the most popular of all, contains in 500 grammes about 3 of iodine and bromine compounds. The smallest baths used contained 50 litres or 100 lbs., = 50,000 grammes; the 3 grammes added to this gives a proportion of 0·006 of iodine and bromine compounds. Grown-up people no doubt were ordered 1 or even 2 litres; but in a bath containing 200 to 300 litres the dilution was still greater. And if we must now admit that the ordering such small quantities in private practice was in fact a sham ordering, what is the justification for using mother lyes at all? It seems really to have been the result of following an ancient, somewhat mystical belief in the action of salts, without reference to the quantity in which they were present. In imitating natural salt baths, we are thus constantly ridiculously behind our originals. The grounds of this are two; first, if we are to tell the truth, the carelessness of the physicians, who had forgotten to calculate the proportion of salts necessary; and, secondly, the increasing dearness of the materials of the bath. We are thus brought to face the fact that our country is rich in a material which is easily procured, yet is proscribed from common use by artificial circumstances, and especially by taxation.

In the hopes of getting the tax taken off salt that was to be applied to bathing purposes, I applied to the minister of commerce, and asked whether the rough salt which, as supplied to chemical works, pays only a small duty, might not be subject to an equally low rate of tax when supplied for baths; but there were financial difficulties in the way, and the minister obligingly called my attention to the so-called Stassfurt bath salt.

This is a rich potash salt, which is found in a natural state in Stassfurt; its average constitution is as follows:—

	Per cent.
Chloride of Potassium	16·8
Chloride of Magnesium	26·5
Chloride of Sodium	13·6
Sulphate of Magnesia	11·6
Water, etc.	31·6
Total	100·0

It will be observed that there is not much chloride of sodium here. Other chlorine compounds predominate, especially chloride of magnesium, and the composition resembles that of a mother lye rather than of a salt spring; nor does it strongly resemble the saline contents of the water. The water of the Atlantic Ocean contains nearly three and a-half per cent. of salts, which consist of—

	Per cent.
Chloride of Sodium	76·05
Chloride of Magnesium	9·0
Chloride of Potassium	4·0
Bromide of Sodium	1·15
Sulphate of Lime	4·60
Sulphate of Magnesia	5·20
Total	100·0

Notwithstanding its difference of composition from salt springs or sea water, the Stassfurt salt is coming every day into more extended use; and I have myself frequently used it up to the strength of 4 per cent., and with exactly the same effect as salt baths of the same strength.

Its great advantage is its cheapness; 1lb. costs only about two pfennigs (one-fifth of a penny); it therefore can readily be employed in poor-houses and hospitals. But we must be more accurate for the future in ascertaining the exact strength of the baths supplied. For all ordinary purposes it is enough to imitate the strength of the weaker salt springs or of the ocean, and give a bath containing from 1 to 4 per cent. of salt. For the earlier ages from 1 to 2½ per cent. is strong enough. For adults, unless under special circumstances, it should not be weaker than 3 per cent. Calculating the amount of water, a child's bath requires from 1 to 2 lbs. of the salt; an adult's, 12½ to 16½ lbs. The rich have usually larger baths, and may require 48 lbs.

But another kind of salt also occurs at Stassfurt, containing a larger quantity of chloride of sodium; its chemical composition is as follows, according at least to the latest analysis of it:—

	Per cent.
Chloride of Sodium	43·0
Chloride of Potassium	9·4
Chloride of Magnesium	12·8
Sulphate of Magnesia	15·6
Sulphate of Lime	1·5
Water	17·7
Total	100·0

Viewed chemically, this compound comes nearer sea salt and various mother lyes, and would therefore seem better adapted for our purpose; but, practically, a portion of the salt is not only very insoluble, but it swells before it dissolves. Possibly these disadvantages may be overcome, and it is to be hoped that they may be so, as this salt is even cheaper than the last-named one.

In any case, there is no longer any difficulty in supplying salt baths to the poorest patients; and we must have a complete reform of baths of this kind. Their strength can no longer remain a matter of guess work. Their percentage of solids must always be ascertained with a hydrometer. It will also save time in preparing baths, if concentrated solutions of the salts be kept ready, which may be poured at once into the baths, and will prevent the delay of waiting for the solution of the salt, if put in in its solid state. There would be no difficulty in having artificial baths on a large scale, in introducing carbonic acid into the solutions of the salt, and in having inhalation-rooms; and the managers would have their establishments more under control than the proprietors of natural waters have their ones.

No doubt natural salt baths will always retain the advantages they possess—in locality, in climate, and in amusements; and will continue to be resorted to in summer. But rivalry will lead to their exact composition being more minutely studied; and, indeed, the whole subject of the operations of chlorine compounds on the system requires to be more fully investigated. Possibly other analogous salts might have the same effect.

[Of late years, the exaggeration which has prevailed about the strength of sool baths, and the fabulous amount of iodine they were supposed to contain, has been pretty well exposed. Dr. Siegmund's paper will help to enforce more precision. In Germany, where sea bathing is entirely beyond the reach of the mass of the people, sool baths have always been favourites, and they are growing in popularity. In England salt baths have been much neglected. Sea bathing is rarely pursued systematically; and it is only of late that the idea of adding to the strength of sea-water baths has been thought of. Of weak sool baths, England has Woodhall Spa, tolerably prosperous; Ashby-de-la-Zouche, used a little; and Victoria Spa, we believe, closed. The only strong sool baths in England are those of Droitwich, to which place and to its new bathing establishment the *London Medical Record* has several times called attention during the last two years. —*Tr.*]

CRYSTALLIZED ACETATE OF AMMONIA.*

BY M. BERTHELOT.

The author describes the preparation of this salt which he believes had not previously been obtained pure in an isolated state; the crystalline substance that is sold in commerce under this name being ordinarily an acid salt analogous to the binacetate of potash formerly met with, and containing acetimide when it has been prepared with heat.

The author states that the true acetate of ammonia may be obtained in the solid form by evaporating the solution in the presence of an excess of ammonia, and finishing the operation at a low temperature. In operating he dissolves glacial acetic acid in caustic ammonia in a cooled retort, taking care to add sufficient water to prevent crystallization during the saturation, which would give an imperfect product. The mixture is then evaporated in a water-bath in a current of dry ammoniacal gas until the liquid solidifies upon cooling. It is then introduced into a large capsule which is placed under a large bell glass with caustic lime, and a considerable quantity of gaseous ammonia is injected under the glass. After an interval of several days, the bell glass is removed, the crystalline mass is coarsely broken up so as to facilitate the penetration of the ammonia vapour, and the capsule is replaced over the

* *Journal de Pharmacie et de Chimie* [4], xxi., 183.

lime with more gaseous ammonia. The operation is slow and requires several months to complete it, but the author states that he has thus prepared by it some hundreds of grams of perfectly pure acetate of ammonia. It is an extremely soluble salt, crystallizing in large needles analogous to nitrate of potash and resembling formiate of ammonia. The salt has no acid reaction. Its analysis yielded 21·9 NH_3, the formula $C_2H_4O_2NH_3$ requiring 22·0. Its solution in water disengaged a small quantity of heat. It is approached by the acetates of potash and of soda, which are also obtained anhydrous by drying them at the ordinary temperature and which disengage heat in dissolving.

SUGAR, CHEMICALLY AND OPTICALLY CONSIDERED.*

BY HENRY POCKLINGTON, F.R.M.S.

I propose in this paper to confine my remarks on the chemistry of sugar pretty closely to the department of applied chemistry, since it strikes me that a chemical audience will most probably know a good deal more of sugar from the pure chemist's aspect than I do myself. I shall also restrict myself almost exclusively to that variety of sugar we call in popular language cane sugar, and, otherwise, sucrose. I shall assume, as I say, that you know already that this sucrose is a chemical compound of CHO in the equivalents respectively of 12, 22, 11; that it is allied to, and speedily may be transformed into, fruit sugar, or fructose $C_6H_{12}O_6$, and into glucose $C_6H_{12}O_6$ H_2O; fruit sugar being (and this is of biological interest) intermediate between cane sugar, or sucrose, and starch sugar, or glucose. I shall assume also that you know that cane sugar crystallizes readily in four-sided prisms with rhomboidal bases, but are often apparently cubical, and that sometimes, very frequently indeed, they become six-sided prisms. You know also that sugar is intensely sweet, that it is soluble in cold water, extremely soluble in hot water, that it is much less soluble in dilute alcohol, and that it is practically insoluble in absolute alcohol (·52 per cent.) Pure cane sugar has neither colour nor smell. Its crystals are remarkably bold and sharp in outline, however small they may be, and they are beautifully white and translucent. Grape sugar, as you know, differs from cane sugar to a considerable extent. It is, in the first place, only about half as sweet; when it crystallizes at all, it is in fibrous masses or tufts radiating from a centre. The crystals are exceedingly minute and indistinct. It is less soluble in cold water than cane sugar. Fruit sugar does not crystallize at all.

I have taken the liberty of recalling these facts to your mind, because we shall need them as we proceed, as we shall also the additional important fact that, viewed from one aspect, sugar is an exceedingly stable compound, that is from the side of what I may call its individuality, inasmuch as it does not readily enter into combination with other substances, its compounds are not numerous, nor, with the exception of its lime salt, are they of importance. On the other hand, cane sugar is exceedingly prone to change in the presence of heat and moisture. Quite unchangeable in a dry air, and very indisposed to change when pure in pure water at a low temperature, it rapidly passes into fruit sugar and glucose in the presence of warmth and water, and under the influence of dry heat passes through a series of changes of considerable interest economically and theoretically, as we shall see later on.

Having thus, as I think, cleared my ground, I will discuss as briefly as I can the applied chemistry of sugar. By this I mean, chiefly, the manufacture of sugar.

Sugar, as we all know—for were we not taught it as children—is obtained from the juice of the sugar cane, and also from the beet. It is obtained from other plants too, from the *Sorghum*, from palms, etc., and exists in nearly all sweet roots, as those of the parsnip and carrot; and in sweet nuts and fruits, as those of the walnut and hazel. But, practically, we obtain cane sugar only from the sugar cane and beet. The sugar cane, as we all know, is a member of the great grass family, from which we derive so many essentials or luxuries in our dietaries. It is a native of, and best thrives in, tropical and sub-tropical climates—anywhere, in fact, where it is not exposed to frost. It is cultivated largely in the West Indian Islands, in the Mauritius, and in India. In Australia and in Queensland its growth is becoming an important industry. I have specimens on the table drawn from various other less known sources, including a very fine specimen produced in Egypt, and an interesting sample from the Fiji Islands.

The cane grows to from 12 or 15, or occasionally to 20 feet high. The stem has a diameter of about an inch and a half, is dense, brittle, with a hard shining rind, green in colour whilst growing, but changing to yellow when mature. It is jointed like all other grass stems, the joints being from 3 to 6 inches apart. Its leaves are alternate, and given off from the nodes, are from 3 to 4 feet long, flat, straight, and pointed, and from 1 to 2 inches broad, sea green in colour, embracing the stem at the base, and very minutely serrated along their edges. When the canes are about a year old they put forth at their apex a shoot from 7 to 8 feet long, with a diameter of about half an inch. This shoot has no joints, and is terminated by an ample panicle of very numerous flowers, white or very pale lilac. In cultivation, the canes are not allowed to flower, but are propagated by cuttings of a foot or so in length, which are planted in rows four to six feet asunder, the cuttings being four to five feet apart, due provision having to be made for air and light. To provide access by carts, etc., the rows are divided into blocks of a few hundred square feet, separated by appropriate roadways. When the canes are ripe, that is just as they change to yellow, they are cut down and at once conveyed to the mills.

We now have to deal with the cane from the sugar-producing point of view. According to M. Dupois' analyses, made at Guadeloupe, the constitution of the cane is as follows: *—

Water	72·0
Sugar	17·8
Cellulose	9·8
Salts	0·4

A more recent analysis by M. Casaseca of the old creole cane, at Cuba, gives:—

Water	77·8
Sugar, etc.	16·2
Wood and fibre	6·0

M. Icery, still later, in his researches on the juice of the sugar cane, gives as the average composition of Mauritius cane *juice*:—

Water	81·
Sugar	18·36
Mineral	0·29
Organic	0·35

This last named author has made a further very interesting series of analyses of the chief species of cane under cultivation, but I am afraid I must not give you the details or our time will be gone before we well know where we are. It may suffice to say that he finds that the species known as Virgin Bellouguet contains in the body of the cane 13 per cent. of sugar, all of it being crystallizable, and in the head of the cane, and please bear this in mind, only 7 per cent. of which 5 per cent. was crystallizable or cane sugar, the notable quantity of 2 per cent., nearly a half of the whole, being fruit sugar. A variety of cane known as Virgin Diard, contained in the body of the cane the large percentage of 18·2 sugar, of which 17·9

* Lecture delivered before the Leeds Chemists' Association.

* *Practical Magazine*, 1874.

was cane sugar, and 0·3 was fruit sugar. Bellouguet cane reached 20 per cent. of sugar, whilst on the other hand a mixed harvest of recent sprouts gave only 6·8 per cent. of sugar, of which 4·2 were cane, and 2·6 fruit sugar. It is interesting to notice before we pass on the gradual development of the sugar in the cane as shown by the increments in amount found in analyses of the same species at different ages. Payen for example found in Otaheitan cane at one-third of its development as follows:—

Water	79·70
Sugar	9·06
Cellulose	7·03
Albumen	1·17
Starch, etc.	1·09
Fats, etc. / Oils and Silicate	1·95

When mature he found the water had decreased to 71·04, and the sugar increased to 18 per cent. The cellulose also had, of course, increased, to 9·56, but the minerals, fats, and starches, had all decreased.

We may note here that there appears from the best researches to be a period in the history of the cane when the cane sugar is at its minimum, and that at this period the inverted sugar present as its minimum being, according to Icery, only ·004 of the cane juice or ·02 of the cane sugar present. At this period of the cane's history it is said that minute crystals of sugar are to be seen by a lens, distributed through the whole of the more fruitful saccbariferous tissues, viz., those between the first knots of the root and the green leaves below the panicle. It has also been found that the proportion of fruit sugar present increases pretty regularly as we ascend the stem, and reaches its maximum in the growing point of the stem where it is shielded from all action of light. This is a point of which I am sure you will see the significance. It is also worthy of note that canes too rapidly developed contain a notable quantity of fruit sugar, in one case mentioned by M. Icery as much as in the proportion of 2·4 per cent. as against 3·6 per cent. of cane sugar. These canes, as you will probably guess, are the sickly children of the family, and have rapidly run up in the shade without adequate sun and air. The fruit sugar thus found in the cane appears to have special and peculiar physical properties, but they have not as yet been fully worked out.

The juice is expressed from the canes by means of cylindrical presses or rollers. These may be of stone, as in the large old mills, or of iron, as in the newer mills. These rollers are driven by either water, wind, steam, or by beasts. Steam power is the preferable, and by its aid a larger percentage of sugar is obtainable from the canes. The most improved presses are formed of three rollers of cast-iron placed horizontally in a very strong fitting and so arranged that they may be approximated to each other by any desired distance, so that the pressure upon the canes may be varied at pleasure. One of these rollers is driven by the prime mover and itself communicates motion to the others. The canes are brought to the rollers by an endless cloth and passed through the first two cylinders, where they are flattened and half pressed. They then fall down a metal incline, and are passed through the next roller at a higher pressure. It is essential that the speed throughout should be low. Heating the rollers by steam has been found to expedite the process, and to render the expression of the juice more complete. But we must bear in mind that it is desirable not to exhaust the cane too completely, otherwise its value for fuel will be lost. The diffusion process is not applicable in most of our colonies for the same reason.

From the mills the juice flows into a large reservoir where it is allowed to "rest" a short time, for the purpose of clearing itself from suspended matter, woody *débris*, etc., and is then passed to the boilers.

Five of these boilers form what is called a "set." The whole of these are placed upon one fire which is fed by the trash from the mills,—that is, the canes from which the sugar has been expressed,—in order that fuel, a very important item, may be economized as much as possible. In the first of these boilers the juice is mixed with 2 to 3 per cent. of lime which causes a thick scum to arise, and forms with the albumen a copious floating precipitate, and also neutralizes any acids present. The scum is skimmed off and the juice is passed into the second boiler where the evaporation commences, thence into the third boiler or flambeau, into the fourth, and finally into the fifth, or battery boiler. This process results in a serious loss of sugar as will be seen from Payen's analysis, which shows that 55 to 65 in every 160 parts of sugar only are obtainable whilst 25 to 20 parts are absorbed or inverted, and as much as 80 to 75 parts left in the trash, so that not more than 44 per cent. of sugar is recovered from that found in the cane. I am indebted to the *Practical Magazine* for certain of these data.

A considerable portion of this loss is due to the high temperature at which the cane juice is evaporated, causing the transformation of a considerable portion of the cane sugar into glucose. To obviate this evil, two methods have been adopted; the one, the most useful where an adequate supply of water can be obtained, is that known as the vacuum pan method. These vacuum pans are closed vessels, often of great size, from which the air is partially exhausted by powerful air pumps. The working of this will be at once seen if you bear in mind that water which boils at 212° F. in the open air will boil at about 1° lower temperature for every half inch (·589) the barometer is depressed, and since in a good vacuum pan, fitted with proper condensers for condensing the vapour given off by the boiling fluid, we can depress the mercury column to a single inch, we can boil water at a very low temperature indeed, at about 120°, or even less. At this temperature the sugar is slightly changed, but the change is by no means comparable with that due to the higher temperature.

The other method to which I have referred is that which involves the use of what is known as the concretor, which has been described as follows:—

"The cane is crushed and the juice clarified or defecated in the usual way. After the defecation the juice passes on to the 'tray' of the concretor. Here it is concentrated up to about 30° to 33° Baumé at which density it passes into the 'revolving cylinder,' also forming a portion of the apparatus. The interior of this cylinder is full of spiral blades of iron. As the cylinder revolves these spiral blades take up the concentrated juice or syrup, and expose a very large surface of it to the action of a current of hot air drawn through the cylinder by a fan, which forms part of the machine. The evaporation in this cylinder is conducted entirely by means of hot air, the consequence being that though the evaporation proceeds rapidly, the temperature of the juice or syrup is kept low; indeed, on entering the cylinder, the temperature of the syrup at once falls to about the temperature at which it would be boiled in a vacuum pan."

Sugar made by the use of the concretor can hardly claim to be called sugar at all. It is really dried cane juice and contains all the nitrogenous and other soluble matters of that juice, and is obviously unfit for dietetic purposes. Its sole use is for refining, and even refiners have a dislike to it on account of the mineral salts it contains, which act very injuriously upon the syrup, rapidly transforming it into glucose, and also upon the charcoal used in refining.

You will have gathered from what I have said of the various processes by which sugar is obtained from the cane that there is a wide variety in the qualities imported into England, if, indeed, you did not know this already from observation of the grocers' windows. But I am inclined to think that general notions of this diversity are much more restricted to matter of colour than the facts warrant. It so happens that, except to the specially skilled, the appearance of a sample of sugar affords a very poor guide to its sweetening powers, and still less to the quantity of sucrose it contains. It is, in fact, quite possible, as I shall show almost immediately, that a white sugar contains less sucrose per cent. than a much darker sugar, and that the darker sugar is not only the richer of the two in sweetness, but also by far the most wholesome and the cheaper.

I have here this evening a number of specimens of sugar kindly placed at my service by the Messrs. Finzel, of Bristol, who are, as you are aware, the largest refiners of sugar of the kingdom; and by the kindness of my friend, Dr. F. W. Griffin, I am in possession of the results of many hundreds of analyses made by him during the past few years. I have also myself made very careful analyses of some of those on the table, and of various samples purchased in this town and elsewhere. With your permission, I will read a few of the most striking results of our labours. The specimens are here so that you can judge of their appearance.

Havana, 87 per cent.; St. Vincent, 89 per cent.; Barbadoes, 90 per cent; Havana, 94 per cent; Syrupy Java, 86 per cent; Egyptian, 99½; Fiji Islands, 83; St. Vincent, 82; Cuba, 86; Clayed Manilla, 85; Maccio, 87; White Bengal, 97; Kemble's Cuba, 95; Porto Rico, 89½; Havana, 97½; Nazareth, 86; Syrupy Mauritius, 90; Havana, 93; Java, 96; Pernambuco, 87½; Paraiba, 83½; Mauritius, 97; Clayed Pernambuco, 91; Havana, 95; Porto Rico, 89; Pernambuco, 88; Bahia, 92; Havana, 94; Paraiba 91; Guatemala, 91. Summarizing a number of Dr. Griffin's analyses, I found that an average of 19 samples of Bahia sugar shows 88 per cent.; 15 samples of Demerara give 89 per cent., and four samples Barbadoes give 88 per cent.* If you compare these results, and they are quite reliable (those that I have worked over are abundantly confirmed), with the same analyst's analysis of the crystals on the table, you will find there is a wide difference between the two, ranging from 12 to 7 per cent., which difference arises out of the various impurities with which, even the best (these averages include no very bad samples), raw sugars are contaminated. You will find these crystals, which are, I might say, the ordinary manufacture, some of them made before my own eyes during a flying visit to the refinery of the Messrs. Finzel, are practically chemically pure. They contain by chemical analysis 99·90 per cent of cane sugar, and form the best standard of purity we can have for the purposes of the method of analysis we pursue, and to which I shall refer at some length presently. How the differences between the coarsest and darkest of the raw sugars on the table and these crystals have been removed, I propose now to tell you; and I do not know that I can do much better than describe the process as I saw it myself during one of several visits I have had the pleasure of paying to the Counterslip refinery.

The process of refining may be classed under three heads. It consists, firstly, in the removal of mechanical impurities. These are exceedingly varied and consist, as I shall show elsewhere, on a future occasion, of varying amounts of portions of the tissue of the cane, sand, earthy matters, the abominable itch insect, whose likeness I have the pleasure of showing you, and various other sorts of matter, too numerous to mention. It consists, secondly, in the removal of the colouring matters due to overheating and to the retention of some of the normal colouring matters of the cane or beet. And lastly, to the removal of the grape and fruit sugar with which all raw sugars, except perhaps raw beet, are more or less contaminated. The first of these classes of impurities may, as you will at once see, be removed by mere filtration. The second may be removed by washing, as in the process of claying sugar and in the final process of crystal or lump sugar making, or much more completely, by the use of the wonderful decolorizing powers of animal charcoal or bone black. We can practise both these processes experimentally. We have only to take some of this yellow beet sugar and wash it with strong alcohol to remove, as you see, most of its colour, and we have only to take some of this black St. Vincent, dissolve it in water and agitate it with bone black for a short time with subsequent filtration to procure a perfectly white syrup. We shall better secure this end if we pass the sugar solution through a long column of the black, but this the limits of our time will not allow us to do. The exclusion of the last of our classes of impurities, the grape and fruit sugars, can only be secured by means of that wonderful law by which Nature when she makes a crystal always does her best to make it a pure and a perfect crystal. Instances of the working of this law have been tolerably frequent during the past month, and you must all have observed them. Looking into any of our street gutters or little pools of dirty water by the wayside you cannot fail to have seen little spiculæ of the purest ice, or a solid covering of clear ice hardly less pure or less brilliantly white than the snow from heaven. It is by means of this law, by working with and encouraging nature in her endeavours after the purest and best, that these crystals have been obtained. The process I will briefly explain.

The sugar is first dissolved in warm water by the aid of steam ingeniously applied and the resulting syrup is strained through canvas and then passed through animal charcoal in large upright filters, many feet in height, called in the Bristol works—"Joeys." The importance of these filters and of bone black may be at once seen by the visitor to the refinery if only when he sees that two-thirds of its immense area are devoted to it in some way or other. The syrup leaves these filters perfectly white and is then transferred to the vacuum pans, where it is boiled for a greater or lesser time at a temperature proportioned to the kind of sugar in process. Now, there is one important fact connected with this manufacture of crystal sugar that struck me very much when I first saw it. It is this, that the crystals are formed, not in quiescence but during the most tumultuous ebullitions in the vacuum pans. Looking into these pans through a glass window provided for the purpose, you see a yellow tempestuous sea; and it is in this that the most perfectly formed and the purest crystals are formed. Faraday has, I believe, shown that under certain conditions perfect purity of ice crystals can only be obtained when the congealing water is kept stirred by a feather. The result as regards the purity of these crystals is shown very satisfactorily by Hassall's, Griffin's, and Cameron's analyses of them, which coincide very closely in giving as the amount of sugar 99·92, the remaining portions being about ·069 of hygroscopic moisture, and ·02 of ash. My own observations on their specific molecular rotation quite confirm this view of them, and I think there is no room for doubting they are pure sugars. But to return to our sugar syrup. It is taken from the pans to a kind of drum with perforated sides, into which it is thrown. The drums are then caused to revolve at the rate of about 1000 revolutions per minute, and, in a few minutes, by virtue of that law of centrifugal force which enables a housemaid to drain her mop by twirling it, the crystals are freed from their mother liquor, and a slight washing by a stream of water, or clear syrup, whilst the pan is in motion, removes any adherent syrup, and the crystals are dry enough to be wrapped in paper and placed in your pocket, if you are so fortunate as to gain permission.

Time scarcely allows of the description of the process of lump sugar making, which, however, so closely accords with that described above that little need be added beyond this—that the centrifugal pans are replaced by conical moulds, into which the syrup, when properly concentrated, is placed, and the moisture allowed to drain away through a hole in the apex of the mould, which points downwards. When the syrup has run off, the sugar is washed, as in the former cases, and the loaves removed from the moulds, turned in a lathe and dried in a stove.

* Cheap white moist sugars do not compare favourably with these results, as will be shown in another place.

After some further remarks on the purity of commercial sugars, the lecturer described at considerable length the optical characteristics of sugar and the various methods pursued in making polarimetric analyses, including a description of the apparatus employed; but this portion of the lecture is withheld from publication for the present by request of the lecturer; it will be incorporated to a certain extent in a series of articles now in course of preparation on the technical uses of polarised light.

THE OCCURRENCE OF ORGANIC FORMS IN CONNECTION WITH CONTAGIOUS AND INFECTIVE DISEASES.*

BY J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

LECTURE II.

CHANNELS BY WHICH BACTERIA MAY ENTER THE ANIMAL ORGANISM.

In the bodies of men and of the higher animals, there are innumerable doorways by which particles as small as septic bacteria must constantly enter, yet no putrefactive changes occur. Bacteria, as we have seen, are, if I may so express myself, potentially present in all articles of food; for every kind of ordinary liquid has the faculty, when added, even in the smallest proportion, to a "cultivation liquid" (*i. e.*, a liquid fitted to serve as soil), of determining at once the development of bacteria. The fact that, even when we employ the highest powers of the microscope, we can see absolutely nothing in these liquids, only teaches us that our modes of observation are insufficient; for we have the proof, not merely that they act zymotically, but that we can deprive them at will of this power, either by heat or by agents such as carbolic acid, which are destructive to bacterial life. Thus, in ordinary drinking water, in cold meat, in fresh vegetables, in cheese above all, and in all ordinary specimens of milk, we are constantly taking in efficient sources of saprogenous life.

When such aliments come into operation with the absorbing apparatus of the intestine, whatever of course is chemically soluble enters the blood-current by the veins, while the insoluble parts enter the lymphatic system by the villi. The mechanism of absorption by the villi is such that even inorganic solids, in a state of fine division, are very readily taken in, and thus find their way from the intestinal cavity into the lacteals, through the thoracic duct, into the blood-stream. Anatomically, this was formerly very difficult to understand; for, so long as it was supposed that the epithelial covering of the villi was set on a structureless hyaline basement-membrane, it was difficult to see how particles could pass through such a membrane. Now we know that this membrane is not structureless, but that here, as in other examples of supposed structurelessness, the substance is penetrated by channels lined with protoplasm, which in the one direction are ready for the taking in nutritive particles, especially oleaginous ones, and in the other communicate with the commencing lacteal.

But, before these anatomical conditions were known and understood, it was proved experimentally that solid bodies in a state of fine division readily entered the lacteals. It is a great many years since Oesterlen showed that, if charcoal in extremely fine powder were mixed with the food of animals, the particles could afterwards be found in the circulating blood. *A fortiori*, therefore, if bodies relatively so enormous as charcoal-particles can be taken into the blood-stream by the villi, bacteria must certainly get into the vascular system whenever they are present in the intestinal liquids. Yet, notwithstanding the ubiquitousness of bacterial germs, it is manifest that the chance of their entrance into the organism by the intestine must depend in a considerable degree on the quality of the food, and particularly on its liability to septic change, and on the readiness with which its constituents are absorbed. Of these two conditions, the latter is likely to be the more influential.

Those alimentary substances which are soluble, as has been already said, enter the circulation by diffusion—a process which would exclude even particles so small as bacteria. But the fatty constituents can only obtain admission by interstitial channels, such as those which form the beginnings of the lacteal absorbents in the intestinal villi. Hence we are led to anticipate that a liquid like milk, of which the oleaginous particles are of extreme minuteness and in enormous numbers, all of which enter the absorbent vessels without undergoing any chemical change, would have a better chance of serving as a vehicle for saprogenic germs than any other sort of food. Whether this is so, is still a matter of speculation. It is supported by what was ascertained in the inquiry relating to the remarkable epidemic of typhoid fever in London last year. With reference to that epidemic, it was, I think, clearly shown that the spread of typhoid was due to a widely spread contamination of a certain supply of milk; but it was not shown what was the nature of that contamination.

Notwithstanding the trouble that was expended in the research, it cannot be admitted that a case was made out in evidence of its specific origin—*i. e.*, its origin from previously existing cases of typhoid fever. This question must, I think, be allowed to remain open. For my purpose it is sufficient that it was contaminated, and that the contamination had a very wide distribution. For if this be admitted, a practical lesson may be learnt from it—*i. e.*, that if it happened once, it may and will happen again; and that greater precautions against contamination than are at present used are necessary. In England we use our milk raw. In Germany, and in all countries in which acid fermentation products are consumed by the population, the milk is all boiled at the dairy before anything else is done to it; for, if it were not so, it would not be possible to produce sour milk, without constantly running the risk of septic fermentation. It would pass through the stage of lactic acid fermentation into that of putrefaction. I have myself ascertained experimentally that it is not possible, as regards London milk, to keep it until it is acid without its becoming at the same time putrid. Sour milk, as used in Germany, is a refreshing and wholesome beverage, but a little leaven of septic bacteria is sufficient to deprive it of both these qualities, as any one knows who has attempted to prepare it from London milk.

The other doorway for the introduction of bacteria is the mucous membrane of the lungs. Experiment has proved that, in animals exposed to a smoky atmosphere, the black particles are absorbed by the mucous membrane, and can be traced step by step along the course of the absorbent channels. It was indeed in this way that the first step was made towards the acquisition of that knowledge of the lymphatic system of the lungs which has lately been brought to comparative completeness by the anatomical researches of my colleague at the Brown Institution, Dr. Klein; for it was by Knauff's experiments* on the effects of a smoky atmosphere on dogs that the manner in which smoke particles find their way through the pulmonary epithelium, and thence into the network of superficial lymphatics, that the course and distribution of these channels first began to be understood. In the pulmonary mucous membrane, we have, then, a second unguarded portal by which morbific particles can enter the animal organism.

GERMLESSNESS OF HEALTHY LIVING TISSUE.

These considerations lead us to another question, which lies nearer to the object we have in view in these lectures

* Lecture delivered at Owens College, Manchester; reprinted from the *British Medical Journal*.

* See my paper on Artificial Tuberculosis, in the *Report of the Medical Officer of the Privy Council for* 1868.

—the elucidation of the relation of bacteria to disease. From experiments made in 1871, I came to the conclusion, that the blood and tissues of healthy animals were barren; that is, that, when subjected to conditions of temperature favourable to the development of microphytes, no such organisms were developed in them, provided that they were protected from external contamination. The general truthfulness of that conclusion has been confirmed by better and more exact experiments than mine, so that "barrenness" may now be accepted, as regards muscle and blood, as a criterion of health. But, from recent experiments which have been made at Heidelberg, under the direction of Professor Kühne,* and which I have lately repeated a good many times, following his method exactly, it appears that the negative property of germlessness is not one which belongs to all organs, and that, in particular, those parts of the animal body which are in closest proximity to absorbing mucous membranes are most liable to be found pregnant with microphytic life when tested by suitable methods. Kühne's mode of experiment is as follows. An animal having been killed by opening a large artery, the organ of which the germlessness is to be tested is rapidly exposed, and a small bit cut out with a sharp scalpel, to which a previously boiled silk cord is attached. The preparation is then, without a moment's loss of time, dipped in paraffin at 120 deg. to 130 deg. cent. (about 250 deg. to 260 deg. Fahr.), and immediately afterwards withdrawn, allowed to cool, and again dipped. This process having been repeated several times, it is finally plunged into paraffin at a lower temperature (52 deg. cent. = 125·6 Fahr.), and allowed to remain until the whole mass (which is contained in a paper box like that used by histologists for "embedding") is cool. The thread having been burnt away, the whole is covered by an additional layer of paraffin, and the cake is placed in the "warm chamber" at a temperature of 30 deg. cent. (86 deg. Fahr.) In this process, the surface-layer of the embedded bit of tissue is of course cooked, *i.e.*, its albumen is coagulated, but the interior remains unaltered. If the tissue be germless, it remains free from organism, and is found to be so when the preparation is examined microscopically after remaining four or five days in the chamber. I place before you several such cakes of paraffin, some containing muscle, others liver, kidney, or spleen. I cannot assert that any of them are free from organisms, but it is quite possible that that of muscle may be. As regards the others, I will answer for it that all are full of bacteria—bacteria, be it understood, of which the germs unquestionably did not enter after death—germs which existed and retained their latent vitality in the living tissue. Muscle and blood, if healthy, are germless; liver and spleen never are.†

The experiment I have been describing is by no means the only one by which it can be shown that blood and muscle are germless. As regards blood, the earliest is that of Professor von Recklinghausen, to which, it may be remembered, Professor Tyndall referred in his famous lecture on Dust and Disease. This consists simply in allowing blood to flow from an artery into a platinum capsule which had been heated to redness and allowed to cool. It is then placed in a moist chamber, *i.e.*, a chamber of which the atmosphere is saturated, and kept at the temperature of the body, or rather below it (35° cent. = 95° Fahr.) The blood so kept remains without putrefaction for months, if protected from contamination. The coagulum first formed disintegrates; the colouring matter of the corpuscles leaves them, becomes dissolved in the liquor sanguinis, and crystallizes, if crystallizable; but, after this, no further change occurs. This method has been improved and modified by Klebs; for in the form originally devised it often fails.

Instead of using a capsule, he employs a glass tube of the same nature as the one exhibited at last lecture. When it is desired to collect a specimen of blood, the drawn out end of the tube is introduced into a vein and secured in its place by a ligature. This done, the point (which is of course within the vein) is seized by the thumb and finger and broken off. The tube being half vacuous, the blood fills a great part of it. The tube is then withdrawn, and immediately closed hermetically. The specimens of blood thus collected may be kept for any time without undergoing putrefactive change. If the blood of animals whose colouring matter is readily crystallizable be used, and the temperature be suitable, the liquid in the tube contains crystals of hæmoglobin. Most of it, however, undergoes a peculiar change, which results in the production of an amorphous coloured mass, differing from hæmatin in its insolubility in alkalies.

The other method—that of cultivation—was employed by Dr. Ferrier and myself in our original experiments in 1871. It was by it that the fact of the absence of the septic ferment in the blood was first established. Having found that all exposed liquids possessed what I then called the zymotic property—that is, the power of starting the development of *Bacteria Termo* in Pasteur's liquid—we extended our inquiries, not only to other animal liquids, but also to healthy tissue, and concluded that all the liquids and tissues of the body are germless.*

(*To be continued.*)

* Tielgel, Ueber Coccobacteria septica im gesunden Wirbelthierkörper. (Virchow's *Archiv*, vol. lx, p. 453.)

† It is desirable to note that in the experiments I have myself made with reference to the germlessness of muscular tissue, that of the dog was used. In substituting muscle of the rabbit, I have failed. I believe this stands in relation with the observed proneness of the latter animal to traumatic infection as compared with the immunity of the former.

* Under conditions not as yet sufficiently known, organic forms, probably allied to bacteria, are met with in the blood of healthy persons. About three years ago, a discovery was made simultaneously by Dr. Ferrier and by Dr. Lostorfer, of Vienna, that in certain individuals bodies exist in the blood which in form resemble sarcina. They are to be found in blood which has been received into calcined tubes with all the necessary precautions. If such tubes are kept at the temperature of the body for a week or two, they are found to multiply rapidly. This observation has been confirmed by Cohn (*Beiträge, loc. cit.*, p. 223). A still more remarkable observation was made by Dr. Osler in my laboratory two years ago. He found that in the blood of certain apparently healthy persons, peculiar aggregations of pale particles of extreme minuteness, but definite form, existed in considerable numbers. These were studied under the microscope, on a stage of which the temperature was maintained at 38° (about 100° Fahr.), and exhibited a series of changes, all of which are carefully figured in his paper (*Proceedings of the Royal Society*, No. 153). In short, each aggregation resolved itself in the course of half an hour or an hour into individuals, each of which possessed the power of active locomotion.

CHLOROFORM AND ACONITE LINIMENT.†

Take of Chloroform	2	fluid ounces.
Tincture of Aconite Root	2	„
Soap Liniment . . .	12	„

Mix them.

This preparation has been in use many years in Baltimore under the names of "chloroform liniment," "compound chloroform liniment," and "chloroform and aconite liniment." It differs from the formula of the U. S. Pharmacopœia of 1870, which is as follows:—

Take of Purified Chloroform .	3	troy ounces.
Olive Oil	4	„

Mix them.

THE SALE OF FOOD AND DRUGS BILL.

THE "Adulteration of Food and Drugs Bill," or, as it is now less ominously designated, "The Sale of Food and Drugs Bill," ordered by the House of Commons in Committee to be reprinted with amendments, has now been issued and is set down to be recommitted on Friday the 19th inst. The original Bill was printed at p. 675; but it has undergone considerable modifications.

These modifications have been the result of the nearly unanimous opinion of the public press that unless considerable amendments were made in Committee the Bill would, in the words of Dr. PLAYFAIR, relieve traders from what they considered hardships at the expense of the public. Referring to the provision that there should be evidence of guilty knowledge, as implied by the occurrence of the word "knowingly" in several places, the *Times* remarked that the public cannot allow the retail dealer to "evade his responsibility on any plea of innocence or ignorance." The *Lancet* said "One would think the Bill had been drawn up by a conclave of adulterating manufacturers, who while professing the desire to afford the public some protection against adulteration, yet contrived that the measure should cover nearly every form and species of adulteration." The *Medical Times and Gazette* was of opinion that it had "too evidently been drawn in the interests of trade." The *Medical Press and Circular* stigmatized the Bill as "The Fraudulent Traders' Protection Bill." It was also severely condemned by the *Saturday Review*, and the feeling of a large portion of the public was no doubt represented by the following words of the *Pall Mall Gazette*:—

"It is to be hoped that Conservative reaction will not take the form of undoing the little that has been done for the protection of the public against adulterated food. Such a policy will, no doubt be greeted with frantic applause by a large number of dishonest and disreputable traders, but it will create a very disagreeable impression in thousands of households where even under the working of the present imperfect machinery of the Adulteration Act, pure milk is now thankfully drunk as a pleasing novelty, and will not be relinquished without a feeling of intense disgust and dissatisfaction."

Numerous notices of amendments to be moved upon going into Committee on the Bill were put upon the notice paper, and it soon became evident that it would be a loss of time to discuss the Bill in its original form. It was, therefore, ordered to be reprinted in order to give the Government an opportunity of adopting such of the suggested amendments as it might think advisable. It will be useful here to indicate the more important alterations of the Amended Bill which have been adopted by the Government, as well as those proposed omissions and insertions of which notices of motion have been given.

As has been before mentioned, the title of the Bill has been altered to "The Sale of Food and Drugs Bill." The sphere of its proposed operation, also, which was previously limited by clause 2, has, by the omission of that clause, and the insertion of the necessary provisions in other clauses, been extended to Scotland and Ireland, sheriff substitutes or magistrates in the former country and divisional justices in the latter being now included in the interpretation of the term "justices." Moreover, an addition has been made to the statutes which are to be repealed, in the 33 & 34 Vict. c. 26, s. 3, or the section of the Sale of Poisons (Ireland) Act, extending the Adulteration Act, 1852, to medicines sold in Ireland. The other statutes proposed to be repealed are the Adulteration Acts of 1860 and 1872, and the section of the Pharmacy Act, 1868, extending their provisions to the sale of medicines.

In clause 3 (now 2) the former extremely faulty definition of "food" as "every article *eaten or drunk* by man other than drugs," is altered to "every article *used for food or drink* other than drugs," and this is decidedly an improvement. Mr. STANHOPE proposes to add the words "or water." In clause 4 (now 3) the word "knowingly" is still retained in the Amended Bill in respect to the mixing of injurious ingredients with articles of food and also in respect to the sale of such mixed articles; but Dr. PLAYFAIR has given notice of his intention to move the omission of the word in the first case, and Dr. CAMERON intends to move its omission in the latter case also. The same remarks apply to clause 5 (now 4), where the word "knowingly" is retained in respect to the mixture of drugs with injurious ingredients and to the sale of the same, and notice of motion for its omission in both places has been given.

Clause 6 (now 5), has been much altered. In the first line the words, "No person shall *knowingly* sell any article of food or any drug which is not of the nature, substance, and quality of the article demanded," are altered to "No person shall sell *to the prejudice of the purchaser* any article of food which is not," etc. The word "harmless" is inserted, to qualify the exception as to matter mixed for rendering articles of food portable or for preserving them. The very elastic exception of admixtures, "according to the usages of trade," which was so sharply criticized on the second reading has been expunged, and the same fate has attended the exception in respect to spirits reduced from their ordinary strength. An improvement of considerable importance has been made in the exception in favour of articles unavoidably mixed with extraneous matter, by the addition of the words, "in the process of collection and preparation;" an alteration which, we believe, is due to the representations of the deputation from the Council of the Pharmaceutical Society that recently waited upon Mr. CLARE READ. A provision, however, is retained, that no article shall be deemed to be within any of the exceptions if the admixture exceeds what is required for the purpose referred to.

The first portion of Clause 7 (now 6) is entirely new, and it provides that no person shall sell any compound article of food which is not composed of ingredients in accordance with the demand of the purchaser, under a penalty of twenty pounds. This clause, if retained, would have a very wide scope, and might possibly affect the sale of some popular remedies which are made up according to different formulæ in different localities. But it, doubtless, could be made to meet the grievance of the recent deputation of hop-growers to the Local Government Board, as to the alleged sale of beer containing other bitter substances than hops. The latter part of the clause, which, as it originally stood, might have been construed to interfere with the sale of proprietary (not patent) medicines, or the sale of non-official compounds, has been modified by words allowing the sale of drugs compounded "in accordance with the demand of the purchaser," and "in accordance with the provisions of the Pharmacy Act." The references to the regulations prescribed by the British Pharmacopœia, and to a "basis to be laid down by the Pharmaceutical Society or the Privy Council" are retained, but no mention is now made of the Local Government Board. Further, no explanation is given as to the nature of this "basis," or when it is to be "laid down," or whether the Pharmaceutical Society and the Privy Council are to act jointly or independently in the matter. These two clauses are so important, and have undergone so much alteration that it will be as well to give them in full as they now stand:—

"5. No person shall sell to the prejudice of the purchaser any article of food or any drug which is not of the nature, substance, and quality of the article demanded by such purchaser, under a penalty of twenty pounds, except as herein excepted and provided; that is to say, except—

"Where any harmless matter or ingredient is mixed therewith for the purpose of rendering it portable or palatable, or of preserving it, or of improving its appearance;

"Where it is the subject of a patent in force, and is supplied in the state required by the specification of the patent;

"Where a drug is compounded as hereinafter described;

"Where the article is unavoidably mixed with some extraneous matter in the process of collection or preparation.

"Provided that no article shall be deemed to be within any of the exceptions above set forth, if the matter or ingredient mixed exceed what is required for the purpose referred to."

There is yet another alteration of this clause proposed by Mr. SANDFORD, who has given notice of his intention to move the addition of words providing that when a person has been fined for the sale of an article of food or drug to the prejudice of the purchaser, without knowing it to be of a different nature or quality from that demanded, he may recover his costs with damages from the dealer from whom he may have received the article.

"6. No person shall sell any compound article of food which is not composed of ingredients in accordance with the demand of the purchaser, under a penalty of twenty pounds.

"No person shall sell any compounded drugs except the same shall be compounded in accordance with the demand of the purchaser, or with the prescription in writing of a registered medical practitioner, or with the regulations prescribed by the British Pharmacopœia issued by the General Medical Council, or with a basis to be laid down by the Pharmaceutical Society or the Privy Council, or in accordance with the provisions of the Pharmacy Act, 1868, under a penalty of twenty pounds."

Clause 8 (now 7) referring to the labelling of mixed substances, although re-written, remains substantially the same. But Mr. ALEXANDER BROWN has given notice that he will move the addition of words making it no offence if the mixed article be supplied from a receptacle clearly marked so as to indicate that the article contained in it is mixed and placed where the purchaser may read what is marked thereon.

In clause 9 (now 8) referring to the abstraction of any part of an article before sale and selling without notice, the word "knowingly" is omitted in both places, whilst the penalty is increased from "ten" to "twenty" pounds.

Clause 10 (now 9) stands unaltered in the amended Bill, with the exception of the additions necessary for the extension of the Act to Scotland and Ireland, by which the approval of analysts is in the former country vested in "one of Her Majesty's Principal Secretaries in Scotland," and in the latter in "the Local Government Board of Ireland." A very important amendment to this clause, however, will be moved by Dr. PLAYFAIR, and one that will, in the majority of cases, prohibit the appointment of a pharmaceutical chemist to the office of public analyst. It consists in the insertion, after the provision for the appointment as analysts of "persons possessing competent knowledge, skill, and experience," of the words, "provided that such analysts be not engaged in the trade of buying or selling any article of food or drugs." This amendment is so directly contrary to the tendency which has been manifested on the part of local authorities to utilize the special qualifications of the pharmaceutical chemists for the office, and, if adopted, would have such an effect in still further increasing the acknowledged paucity of persons properly qualified for the post, that it is to be hoped a vigorous opposition will be offered to its incorporation in the Act. And this is the more necessary as the obvious assumption upon which the proposed amendment is based has no good foundation, since if proper arrangements are made, as we have on previous occasions pointed out, it is not at all necessary or advisable in any case that the analyst should know the sources of the articles he is called upon to analyse.

The provision in clause 12 of the original Bill (now clause 11) which, in the event of a purchaser requiring an analysis in a district where an analyst has not been appointed, made it compulsory upon the analyst of a neighbouring district to perform the analysis for a sum "not more than ten shillings and sixpence," is now made dependent upon the payment of "such sum as may be agreed upon." The limitation of ten shillings and sixpence is however retained as the payment for analyses of purchases made within the district for which the analyst is appointed. Further, the provisions of the clause are extended to comprise "drugs" as well as "articles of food."

The next six clauses of the original Bill remain unaltered, with the exception of such change as is implied by the insertion of the word "forthwith" in clause 14 (now 13) in the provision for dealing with the sample when purchased. Mr. MUNTZ is to move the addition of words providing that one portion of the sample shall be submitted to the analyst "within seven days, or if perishable articles, forthwith;" and Dr. LYON PLAYFAIR will move the omission of the words leaving the analysis to the inspector's discretion. Another amendment is to be moved by Mr. PELL, by adding to clause 19 (now 18) words providing that the authority appointing the analyst shall annually transmit to the Local Government Board a return of the number of articles analysed, and shall be entitled to receive out of moneys provided by Parliament for the purpose the sum of five shillings for each analysis towards the expense of carrying out the Act. Mr. MUNTZ will move the insertion of a proviso in clause 20 (now 19) that proceedings shall be taken within twenty-one days of service and that a summons shall not be returnable in less than seven days from date of service.

Clause 20 (now 19) has certain alterations, rendered necessary by the extension of the Bill to Scotland and Ireland; the next clause remains unaltered.

Clause 22 (now 21) is a clause that certainly still requires reconsideration. As it originally stood it limited the power of justices, in the event of a disputed analysis, to referring it to "the analyst of *an adjoining* district." These words are altered to the "analyst of *another* district," and they would therefore limit the reference to persons holding the post of public analyst. Irrespective of the evident fact that it may sometimes be advisable to have the independent opinion of an analyst not holding a public appointment, it is palpable that by such a provision the best advice in a crucial case might be thus rendered unavailable, and, moreover, a decided injury would be inflicted upon the unofficial analysts as a body. However, it is probable that this result is not intended by those who have charge of the Bill, and that a suitable modification could be obtained by proper representation. Two notices of amendment to this clause have already been given. One is by Mr. PELL, to the effect that the reference shall be to persons appointed by the Commissioners of Inland Revenue, and the other, by Sir HENRY PEEK, that it shall be to the Inland Revenue Department, Somerset House, whose certificate is to be final. Sir HENRY PEEK has also another notice of amendment to make it compulsory upon a Court hearing an appeal to award reasonable costs.

With the exception of certain necessary additions in respect to Ireland and Scotland no further alteration has been made in the subsequent portion of the Bill as reprinted, until clause 27 (now 26) is reached, where to the punishment of two years' imprisonment with hard labour for forging a certificate of warranty, are added penalties of twenty pounds each for the offences of "wilful misapplication of warranty," "false warranty," and "false label." The only other alteration of importance is the provision that, in Scotland, the expenses of executing the Act shall be borne by the "police money in counties and boroughs respectively," and in Ireland "by the grand jury cess."

There are, however, two or three important notices of amendments yet to be mentioned. Mr. SANDFORD proposes (clause 24) that where a case is dismissed on the production of a warranty, it shall be lawful for the justices to summon the dealer who has given the warranty. Sir HENRY PEEK proposes (clause 29) that tea proved to be in the same condition in which it passed the Customs shall not render the vendor liable to penalties; and Mr. MUNTZ proposes that tea once examined and allowed to pass out of the Custom House shall not be returned into bond. Finally, Mr. THOMAS HILL proposes that in a certificate relating to milk, butter, or any article liable to decomposition, the analyst shall specially report whether any change had taken place in the constitution of the article that would interfere with the analysis.

We take this opportunity of referring our readers to a letter from Mr. WIGNER, at page 759, in which he repudiates the statement he is reported in the *Chemist and Druggist* of the 15th inst. to have made at a meeting of the Social Science Association last week. We trust that in reference to what was reported to have been said by another speaker on the same occasion there may have been a similar inaccuracy, for the assertion of Dr. DUPRÉ that "with the exception of the milk trade, I know of no class who have practised adulteration to such an extent as pharmaceutical chemists," conveys an imputation entirely without any foundation save one that would be, to say the least, uncomplimentary to the speaker.

SATURATED SOLUTION OF CAMPHOR.

A LETTER from "A PHYSICIAN," which appeared in the *Times* of the 5th inst., has recalled attention to the danger attending the use of a saturated solution of camphor which is in very general use as a domestic remedy for colds and other trifling ailments, and is sold under the name of "concentrated solution of camphor," "Rubini's saturated solution of camphor," or "mother tincture of camphor," frequently without any intimation by label or otherwise of its potent properties. The subject was brought before the Clinical Society in November, 1873,* by Dr. GEORGE JOHNSON, who described some cases where serious symptoms of poisoning followed the incautious use of the remedy, and those cases have since been supplemented by several others, published in the medical journals. We think this subject has an interest for chemists and druggists in a more special sense than was alluded to in the discussion that followed the publication of Dr. JOHNSON'S paper in this Journal which turned principally upon the extra-pharmaceutical question of the rival claims of the homœopathic and allopathic systems of medicine. As there are, no doubt, many pharmacists who are now called upon to supply this preparation, it is of much greater importance to them to agree as to the manner in which it should be sold; and, after the evidence that has been given, there can be little doubt as to the advisability of using a "caution" or even a "poison" label. We are given to understand that this is done by some pharmacists.

"A PHYSICIAN" asserts that this saturated solution of camphor in spirit is in its poisonous potency quite equal to the prussic acid of the Pharmacopœia and four times as powerful as an equal quantity of laudanum, and he points out the danger of its being mistaken for the much weaker solution of the Pharmacopœia, which contains only one-seventh the quantity of camphor. He further states that the taking of 15 to 25 drops of that solution has been followed by epileptic convulsions and apoplectic stupor. The correctness of this opinion was questioned on the following day by Dr. BREE, of Colchester, who stated that he had taken 3 grains of camphor for ten consecutive nights without any other result than a beneficial one. "A PHYSICIAN" replied in another letter that to compare the action of camphor in the solid state and in spirituous solution was misleading, for when the spirituous solution is mixed with the fluids of the stomach the camphor is precipitated in a state of minute subdivision and is more rapidly absorbed, and he alluded to the much smaller relative dose of the solution given in the Pharmacopœia. In this opinion he was also confirmed by a letter from Prince LOUIS-LUCIEN BONAPARTE, who made, some years ago, a therapeutico-chemical research on camphor.

The *Medical Times and Gazette* is of opinion that the fact that a preparation of such poisonous potency can be sold without any warning of its noxious properties is a grave danger, and suggests representations by the Medical Council to the Privy Council as to the advisability of placing it on the list of "poisons." The *British Medical Journal* says, "This homœopathic solution of camphor is as actively poisonous, drop for drop, as the prussic acid of the Pharmacopœia, and we maintain that any chemist who sells it without labelling it as 'poison' should be as liable to censure and to penal consequences as if he sold prussic acid, or the much less powerful laudanum, without a poison label."

* See PHARM. JOURN., vol. iv., p. 402.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

March 17th, 1875.

Present—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Haselden, Hills, Linford, Martindale, Moss, Schweitzer, Southall, Taylor, and Umney.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Eight candidates were examined, of whom *one* failed. The following *seven* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Riley, Charles Reynolds ....London.
Twemlow, Francis Ernest ......London.
Radford, John Storer ....Nottingham.
Dutchman, Walter ....London.
Draper, James William ....Malmesbury.
Hillier, Henry ....Newport, Monm.
Brown, William Braithwaite ...Preston.

MINOR EXAMINATION.

Twenty-one candidates were examined, of whom *eleven* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barrett, Josephus Teague ......Devonport.
Case, William ....Norwich.
Franciosi, Eugène Auguste de...London.
Green, George ....Thetford.
Williams, William Thomas......Fairwater.
Cross, John Thomas.............. Dover.
Pasmore, Walter Frank ....London.
Leslie, George ....York.
Berry, Henry Burton ....Gloucester.
Vernon, William Henry ....Boston.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned *seven* certificates were received in lieu of the Society's Examination:—

Certificates of the College of Preceptors.

Buck, Charles Burton ....Sandgate.
Cock, James ....South Molton.
Gower, Joseph Read...............Tunbridge.
Taylor, Samuel M. ....Notting Hill.

Certificate of the Society of Apothecaries.

Chapman, Harry Dugard ......Brierley Hill.

Certificates of the University of Cambridge.

Carvell, John Maclean......... ..London.
Steward, Alfred ....Great Yarmouth.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The first monthly meeting of this Association for the present session was held at the rooms, Tudor Place, on Wednesday evening, March 10th, Mr. H. W. Maleham, President, in the chair. After the usual routine business, Mr. W. Ward, F.C.S., read a paper on "Our Interests as a Trade Association." The speaker said that of all the schemes put forth by that Association none had produced any real practical or permanent result. The title of "Pharmaceutical and Chemical" had been assumed by them, several courses of scientific lectures delivered, museum specimens collected, and a host of other requisites obtained. Yet it was a lamentable fact, so far as the question of education was concerned, all attempts in that direction had signally failed. The time, however, had come when they would do well to pause and consider whether they had not lost sight of the main principle of association as applied for the purpose of advancing the interests of commerce and supporting those engaged in the trade against the aggression which had befallen many of their *confrères*. After advocating free trade principles as essential elements of modern political economy, and as being the only sound basis upon which the Association should be governed, he objected to any system which would entirely abolish mental culture; for whilst he had chosen the subject of trade interests, he maintained they ought to make that association conducive to the educational advancement of those who came under its influence, and although it was proposed to strike out afresh and pursue a plan wholly different from that hitherto followed—a course he heartily supported—yet he trusted one tendency of the Association would ever be to *elevate*, rather than dwarf the standard of proficiency of those engaged in pharmacy. He instanced several recent cases of prosecutions under the Adulteration Act, mainly attributable to the misinterpretations and blunderings of magistrates; and whilst believing the new Bill would tend greatly to remedy many of the evils which had arisen out of ill-advised and absurd precautions, he expressed a hope that its tendency would not be to retrace steps which in principle were undoubtedly in the right direction. Having next drawn attention to infringements of the Pharmacy Act, he said the sub-committee had already done some good, and had now set out with the full determination of investigating every case brought under its notice. He expressed much regret that the Council in London had not supported the Association in matters of that kind as it might have done. If the Committee appointed for the purpose obtained all necessary information of cases of infringement about which there would be no doubt, he held it was the duty of the Parliamentary Committee to take action at once without their apathy having to be aroused by repeated applications often of long duration, as that Committee would bear him out had not unfrequently been the case. He next dwelt upon the subject of prices, feeling sure it was the desire of a great majority of the trade to arrive at some better understanding. He was well aware it would be somewhat difficult to fix a uniform rate of charge, owing to the circumstances of various neighbourhoods and their demands differing so greatly. It was, however, certain that dispensing prices might be made more equable, and he submitted that for small quantities of dispensed medicines the charges generally made were much below their value, that taking into consideration the time, and care, and responsibility involved, especially in many of the prescriptions of the modern physician, they ought to adopt some scheme whereby to obtain more reasonable and remunerative charges. After urging the importance "to play the man," and call all articles of commerce in which they dealt by their proper names, and not have recourse to the expedients of the quack and showman in order to realize a beggarly livelihood, he concluded by an earnest appeal for full and free discussion of the subjects which had been brought before them as the only means of arriving at the true object he had in view.

At the conclusion, a very interesting discussion occurred on the topics alluded to by Mr. Ward, which resulted in a resolution being carried, moved by Mr. Preston and seconded by Mr. Cocking:—

"That a circular be issued to the members of the trade throughout the town, with a view to the adoption of a recognized charge being made for the dispensing of prescriptions."

After a very cordial vote of thanks had been accorded to Mr. Ward for his very interesting paper, the President announced that at the next monthly meeting of the Association, Mr. Ellinor would introduce the "Milk of Sulphur" question for debate.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The fifth ordinary monthly meeting of the session took place on Wednesday evening, March 10th.

Mr. G. S. Woolley occupied the chair.

The names of twenty-nine new members and twenty-two associates were read by the Secretary, and these gentlemen were duly elected.

Mr. Louis Siebold delivered the fifth of his special course of lectures on the detection of adulteration of common articles of food and drink. There was a large attendance.

In opening his lecture, Mr. Siebold referred to the voluminous literature on tea and its adulterations, and stated that, as he had only one evening to devote to the treatment of this subject, it would be impossible for him to do justice to the researches of Péligot, Zöller, Allen, Wigner, Wanklyn, and others. He must therefore remind his audience of his intention to confine himself, as he had done in the preceding lectures, to the description of such processes and tests as could be readily applied by the average pharmacist. The botanical characters of the tea should be first noted, and for this purpose a number of the leaves should be softened in hot water and then spread out, so as to admit of an examination. The notch at the apex, the marginal serration which stops short at some distance of the petiole, the almost parallel veins which run from the midrib and turn before reaching the boarder, and the characteristic space between the two cells of the stomata would enable the analyst to recognize the true tea leaf and to distinguish it from foreign leaves which may be present in the sample.

The chemical examination should begin with an estimation of the ash by incinerating about one gramme of the tea, dried at 100° C., in a platinum crucible. A pure tea rarely leaves more than 6 per cent. of ash and a residue amounting to more than 8 per cent. would indicate an adulteration with mineral matter. If 8 or more than 8 per cent. of ash be left, the result should be confirmed by boiling a larger quantity of the tea (about 50 grammes) with water, taking out the leaves from the decoction, collecting the sediment on a filter, and weighing, after washing, drying, and igniting it. Ironfilings and magnetic oxide of iron may be detected in the tea by a magnet, or in the sediment from the decoction by chemical means. The presence of small quantities of iron in the ash of tea, however, is no proof of an adulteration, as this metal is one of its normal constituents. Prussian blue is very commonly used in the facing of green tea, and may be detected by treating the tea with water to remove the facing, treating the sediment with solution of $NaHO$, filtering, and testing the filtrate for ferrocyanide by Fe_2Cl_6 which would produce a blue precipitate. The portion of the sediment insoluble in $NaHO$ may be washed and tested for china clay, French chalk, etc. Soluble iron salts such as ferrous sulphate are sometimes mixed with tea, in order to produce a dark-coloured infusion.

They may be detected by treating the tea leaves with water acidulated by acetic acid, filtering and testing the filtrate with ferrocyanide of potassium. Carbonate of sodium and carbonate of potassium are likewise mixed with tea with the object of giving a darker colour and therefore a fictitious appearance of strength to the infusion; the former may be recognized by the persistent yellow flame produced by heating the ash on platinum-wire in the flame of a Bunsen's burner; the latter by the increased alkalinity of the soluble ash. In pure tea leaves the alkalinity of the soluble ash amounts to 1·3 to 1·9 per cent. as calculated for K_2O.

As pure tea yields from 5 to 6 per cent. of ash, of which at least 3 per cent. is soluble in water, and as spent tea leaves leave only about 3 per cent. of ash, of which about 0·5 per cent. is soluble in water, the presence in a sample of tea of less than 5 per cent. of mineral matter, and of less than 3 per cent. of soluble mineral constituents, would point to an adulteration with exhausted tea leaves. Again, if the total amount of ash be high (more than 6 per cent.) and that of soluble ash abnormally low (below 3 per cent.), this would show an adulteration both with mineral matter and exhausted tea leaves.

The determination of the extract is the next important operation. Ten grammes of the powdered tea leaves are boiled with 250 c.c. grammes of water in a glass flask for at least half an hour and the exhausted leaves boiled a second time with the same quantity of water. To make up for loss by evaporation sufficient water is now added to the united decoctions to make up the weight to 500 grammes. Fifty grammes of the clear mixture are next evaporated in a platinum dish at 100° C. and the residue dried until it ceases to loose weight. Pure teas yield from 32 to 50 per cent. of dry extract, and certainly never less than 30 per cent. A smaller percentage than the last named would therefore indicate the presence of spent tea in the sample examined. A very good tea, containing from 45 to 50 per cent. of extractive matter, might, however, be adulterated with spent tea, so that the mixture would yield fully 30 per cent. of extract, and in such a case the mere determination of the extract would throw no light on the adulteration.

The lecturer then described Mr. Allen's process for the estimation of tannin, by means of a standard solution of acetate of lead. The latter is made by dissolving 5 grammes of pure acetate of lead in water and diluting the solution so as to measure a litre. The indicator is made by dissolving 1 part of ferricyanide of potassium in 1000 parts of water and mixing the solution with an equal bulk of strong liquor ammoniæ. Two grammes of the powdered tea are repeatedly boiled with water until completely exhausted, and the strained and united decoctions made up with water to 250 c.c. Ten c.c. of the lead solution are now diluted with 90 c.c. of water, and to this mixture the decoction of tea is added from a burette until all the lead is precipitated, or until a filtered drop of the mixture turns red on the addition of one drop of the indicator, thus showing that a slight excess of tannin has been added. The number of c.c. of the decoction required contains 0·01 grammes of tannin. In green teas the quantity of tannin amounts to about 20 per cent., but it is subject to considerable variation. In black teas, however, it is much more constant, and may be pretty accurately taken as 10 per cent. The average percentage of tannin in spent tea being only 2 per cent., the above test affords a ready and reliable means of detecting and estimating this adulterant. If T represents the percentage of tannin found in the sample of tea, the percentage of spent tea present would be $\frac{(10-T)\,100}{8}$. Having given an experimental illustration of this volumetric process, the lecturer explained Mr. Estcourt's method for the separate determination of tannic and gallic acids in tea, as described in the *Chemical News*, vol. xxix. p. 109. In his opinion, however, a separate estimation of the two acids, though very interesting from a purely chemical point of view, did not possess any practical advantage.

Mr. Siebold will deliver his next lecture, the last of the series, on Food Analysis, on April 14th.

BRISTOL PHARMACEUTICAL ASSOCIATION.

At the meeting of the above Association in January, a Paper on Essential Oil of Cherry Laurel, by Dr. W. A. Tilden, was read; also one on the Presence of Lead Iodide in Syrup of Iodide of Iron, by Mr. W. A. Shenstone. These papers will be printed in an early number of this Journal.

At the last monthly meeting of the Association, Mr. Thomas Bolas, F.C.S., of Charing Cross Hospital, delivered an interesting lecture on Coal Tar and Coal Tar Colours, with experimental illustrations.

At the meeting to be held next week, Dr. Spencer, of Clifton, will deliver an Address on "Pharmacy in its Relations to Modern Medicine."

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

At a meeting of the above Society held on Wednesday, the 3rd of February, under the presidency of M. Planchon, a note from M. Schlagdenhauffen was read, on the estimation of a mixture of arsenious acid and oxide of antimony. It stated that by dissolving a determined weight of such a mixture in water containing Rochelle salt and an alkaline carbonate, and adding a small quantity of indigo, the relation which exists between the arsenic and the antimony may be determined by means of a titrated solution of hypochlorite of soda. The first effect of the reaction is to convert the arsenious acid into arsenic acid and the oxide of antimony into antimonic acid, and it is not until after this double change has taken place that the chlorine contained in the hypochlorite commences to attack the indigo; consequently in the decoloration of the solution there is a clear and precise measure of the reaction that has taken place. M. Schlagdenhauffen has found by experiment that, as might be expected, the consumption of hypochlorite varies according to the relative proportions of the arsenious acid and oxide of antimony. It is, therefore, sufficient to note exactly the quantity of hypochlorite solution used, and the quantitative result to which it corresponds may be ascertained by a simple calculation.

M. Méhu remarked that having had to examine an alleged definite compound of arsenite of antimony, he was enabled to separate the arsenious acid by the simple action of strong alcohol.

A letter upon silphium, from M. Stanislas Martin, having been read, M. Planchon recalled the memoir of M. Oersted* upon the same question, and stated that he did not think it could be affirmed that the *Silphium Garganica* was the silphium of the ancients. According to coins upon which the plant was delineated, there appeared to be no doubt that the plant was a *Ferula*.

M. Desnoix said that he had received from Algeria an inactive *Thapsia* resin, which he thought was attributable to the existence in that country of two very similar species of *Thapsia*.

M. Lefranc said that during a residence in Algeria he had ascertained that the resin prepared from the fresh root is much more active than that obtained from the dried root. He exhibited to the Society specimens of *Thapsia Garganica*, and another species of *Thapsia*, and he expressed an opinion that the plant would gradually disappear from Algeria, whilst attempts to reproduce it by cultivation, judging from experiments made, would give unsatisfactory results.

Parliamentary and Law Proceedings.

Strange Case of Poisoning.

On Monday, March 8, an inquiry was held at Cockermouth into the circumstances attending the death of Isabella Bell, aged 53 years. It appeared from the evidence that the deceased had been found asleep on the roadside, by some persons to whom she represented that she had missed a train. One of them took her in, gave her some tea, and arranged that she should pass the night in her kitchen. Upon going to call her in the morning she was found to be dead. It had been noticed that she snored very heavily.

Mr. Joseph Straughton, druggist, said that a woman, answering the description of the deceased, came into his shop and asked for a pennyworth of laudanum. He gave her five drops with some peppermint and water, and she drank it in the shop. She said she was suffering from a pain in the stomach. The reason of witness giving her so small a dose was because her breath smelt of drink. She said that she had taken gin, and that it did her no good. The dose he gave her would not have caused her to sleep.

In answer to a question from the foreman (Mr. Dent) witness said that if the woman, after leaving his shop, had gone to other druggists' shops and taken seven or eight drops at each it would have had the same effect as if it had been taken in a single dose.

A Juror: I suppose you are only allowed to give them a certain quantity?

Witness: I do not know that there is any particular tie. It is left to our own discretion, and if we poison people we take the responsibility.

Mr. Robinson, druggist, said that a woman answering to the description that had been given him of the deceased, came into his shop at about six o'clock, and asked him to let her have a pennyworth of laudanum. She said she was in the habit of taking it regularly when the pains came on. She appeared to be troubled with spasms in her stomach. Witness told her he would give her thirty drops. She said, "That won't do; it will not have the slightest effect." He then added another thirty drops, which she took. The quantity would not harm her if she was in the habit of taking it regularly, but if she had not been in the habit of taking it it would cause a drowsiness. He had known of people taking three or four times as much every day, and from 220 to 240 drops was not an unusual dose.

A Juror: What is the quantity you are allowed to sell?

Witness: According to the Pharmacopœia it is from 15 to 40 drops, but people who are in the habit of using it daily may take an ounce. If the deceased had been in ordinary health, and had not been in the habit of taking laudanum, the dose he gave her would not have caused her death.

Dr. Dodgson gave evidence to the effect that if the deceased had been in the habit of taking laudanum the doses mentioned as having been given by the previous witnesses would not have killed her. There was, however, a great deal of difference between measured drops and drops counted from a bottle. If measured there would be almost twice the quantity; the proportion was 13½ counted to 25 measured. The snoring referred to by the female witness was a symptom of poisoning by laudanum.

Mr. Robinson, recalled, said he measured the drops.

Mr. Hugh de Bosco Askew, an assistant with Mr. Bowerbank, said the deceased came to the shop at about a quarter past five o'clock, and asked for laudanum. He gave her twenty drops of chlorodyne. She said she did not feel better, and he then gave her two ounces of mint water and half a drachm of sulphuric ether.

Dr. Dodgson, in answer to the Coroner, said that any one of the doses mentioned would not have done much harm, but the whole together, if the deceased was not accustomed to the use of laudanum, would cause her death, and the probability was, judging from the circumstances, that she died by being poisoned by laudanum.

The jury were again left to themselves, and on the door being re-opened, the foreman announced that they had come to the following verdict: "That the deceased died from taking two doses of laudanum and one of chlorodyne in too quick succession. The opinion of the jury is that there is no blame attached to any one."—*West Cumberland Times.*

Poisoning through a Mistake in Dispensing.

The following is reported in the *Edinburgh Daily Scotsman* for Friday the 12th inst., but the name of "Dr. Smith, druggist, Springburn Road, Glasgow," does not occur on the Register of Chemists and Druggists:—

A man named Alexander Jamieson, in the employment of Dr. Smith, druggist, Springburn Road, Glasgow, was yesterday examined before Sheriff Murray, and remitted, on a charge, it is stated, of culpable homicide. It appears that on Tuesday a man named Parker went into Dr. Smith's shop to get a powder for his child. The accused, it is alleged, had mistaken the bottles, and instead of giving the medicine asked for, supplied instead a quantity of strychnine. Parker administered the powder which he got for the child, and the result was that shortly afterwards symptoms of poisoning manifested themselves. Death resulted in a very brief period.—*Edinburgh Daily Scotsman.*

Suicide by Prussic Acid.

An inquest has been held at the Garrison Hospital, Portsmouth, respecting the death of Mr. W. C. Ellis. It appeared that deceased, who had been for some days previously peculiar in his manner, suddenly left the room where he was sitting, and returning a few minutes afterwards, threw a hexagonal purple glass bottle upon the ground, and immediately expired. Medical evidence showed that his death resulted from poisoning by hydrocyanic acid. A verdict of suicide during temporary insanity was returned.

Review.

Die Rohstoffe des Pflanzenreiches. Von Dr. Julius Wiesner.—The Raw Substances of the Vegetable Kingdom, etc.—8vo, 846 pages, and 104 chiefly anatomical wood-cuts. Leipzig: W. Engelmann.

This work concerns the druggist very little, for the author includes only those vegetable products employed as medicine whose preparation is a recognized branch of industry; at least, this is the rule he professes to have adopted, though we can scarcely agree that he has carried it out. Many drugs are included, however, because they are used in perfumery, dyeing, etc.; but the mention of several others seems to have depended upon chance. For instance, storax, balsam of tolu, castor oil, jalap, cardamoms, and asafœtida are mentioned, and, in some cases, fully described, whilst croton oil, rhubarb, senna, grains of paradise, sarsaparilla, etc., are not named. But, as the author does not undertake to provide a work for druggists, this can hardly be termed a defect. Opium, aloes, cinchona bark, catechu, castor oil, etc., are pretty fully described, though not so minutely as in pharmacographical works. The chapter on opium is chiefly from Flückiger's 'Pharmacognosie.' To aloes four pages are devoted, and under the head of catechu group, we have the various kinds of catechu, gambir and kino.

The chapters on fibres, gums, resins, barks, etc., are much more detailed. Taking the first, on gums, as an example, the matter is divided thus · physical properties, chemical properties, origin (secretion) of gum in plants, sources of gums, special consideration of the various kinds of gum. The different substances described are brought under twenty heads, but the arrangement is not so convenient as it appears at first sight. Fibres, fats, starch, woods, etc., have separate chapters devoted to them; but dyes and substances employed in tanning are scattered, some under barks, others under seeds, fruits, leaves, woods, or galls. This would not be of great importance if the index were more complete. In fact, it would be difficult to devise a classification not open to criticism on some point.

We can strongly recommend this work, as it is very complete and accurate, so far as it goes, and is brought up to a very recent date in its information. The references to other works that have been drawn upon are very numerous, and constitute a useful feature of the work. The chapter on the anatomical structure and identification of various fibres is exceedingly interesting, as is also that on starch. The botanical portion is limited to the names, and is generally very correct. After using the book for some time, we have seen very few blunders. Exogonium, however, is spelt Exogossium, both in the index and the body of the work. A few recent determinations do not appear, but that is accounted for by the fact that the first part of the book was printed early in 1872.

A similar work in English would be very welcome.

Notes and Queries.

[432]. PRESERVATION OF FLOWERS.—Will any reader inform me how to preserve flowers in their natural shape?—J. E. Roberts.

*** The following description of the process appeared in the *Pharmaceutical Journal*, [2], vol. vii., p. 36:—A vessel, with a moveable cover, is provided, and having removed the cover from it, a piece of metallic gauze of moderate fineness is fixed over it, and the cover replaced. A quantity of sand is then taken sufficient to fill the vessel, and passed through a sieve into an iron pot, where it is heated, with the addition of a small quantity of stearine, carefully stirred, so as to thoroughly mix the ingredients. The quantity of stearine to be added is at the rate of half a pound to one hundred pounds of sand. Care must be taken not to add too much, as it would sink to the bottom and injure the flowers. The vessel with its cover on, and the gauze beneath it, is then turned upside down, and the bottom being removed, the flowers to be operated upon are carefully placed on the gauze and the sand gently poured in, so as to cover the flowers entirely, the leaves being thus prevented from touching each other. The vessel is then put in a hot place, such for instance as the top of a baker's oven, where it is left for forty-eight hours. The flowers thus become dried, and they retain their natural colours. The vessel still remaining bottom upwards, the lid is taken off, and the sand runs away through the gauze, leaving the flowers uninjured.

Obituary.

Notice has been received of the death of the following:—

On the 14th March, 1875, Mr. John Parnell, Pharmaceutical Chemist, Peterborough. Aged 71. Mr. Parnell was a Founder of the Pharmaceutical Society, and acted as one of its Local Secretaries for many years.

On the 18th February, 1875, Mr. John Bennett, Chemist and Druggist, of Shaftesbury, Dorset. Aged 55.

On the 23rd February, 1875, Mr. William Wilson, Chemist and Druggist, of Hull. Aged 28.

On the 14th March, 1875, Mr. Henry Mills Ayre, Chemist and Druggist, of the Provident Dispensary, Leamington. Aged 27.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

"Thirty Years Ago."

Sir,—In the prolonged discussion of early closing which has almost exclusively occupied your correspondence columns since last November, it is remarkable that no one appears to have apprehended the obvious fact that *the thing is done.* Early closing has been proved to be practicable in pharmacy as well as in other trades by many examples in London and elsewhere, thus solving the ancient difficulty and only wanting time for those examples to spread and for the ball to go on rolling down hill, as it cannot fail to do in spite of occasional hindrances, until it rests at a practicable level.

We have been favoured with some interesting recollections of the usages which prevailed some thirty years ago (and which, if necessary, I could confirm); but it is strange that the writer who so graphically describes the past should be so little alive to the significance of current events as to say in a subsequent letter that "there cannot be much effected in the direction of early closing!" It seems as if the revival of old memories had reproduced old sentiments, for this was the language of *thirty years ago*, but it is inconsistent with later experience. I well remember about that time one who had been brought up under the thraldom of the old system, and who had therefore some excuse for his prejudices, objecting to join in a mild measure of early closing because he was "not going to dictate to his customers when they should send their orders." In those days it really was considered impracticable to close a chemist's shop before 11 p.m., when the weary household retired to bed. Does anyone think so now? If he does, he makes the grievance from which he suffers, for it will naturally happen that so long as the shop is open the public will conclude that they are invited to enter, and they will probably do so upon trifling occasion.

It is unfair to raise difficulties about the supply of necessary medicines after hours as though it were a part of the early closing question, for it is always assumed that provision will be made for such services at all hours of the day or night. Many pharmacists of the highest standing consider it inexpedient to question the necessity of these late summonses, and it seems particularly unwise to give that liberty to assistants. Generally speaking, people will not unnecessarily incur the inconvenience of waiting while a closed shop is reopened, and it is wiser to bear the exceptions philosophically, including the irrepressible pennyworth of hair-oil, upon which depends some poor girl's tranquility of mind and possible attendance at church on the Sunday morrow. Thus, while we forbear, the public are gradually becoming educated to the new state of things.

I should be sorry to see an extra charge levied upon late business, feeling convinced that it would be likely to produce misunderstanding between pharmacists and customers. It is more honourable to ourselves to supply such wants for a human than for a mercenary motive, and it is more dignified to accept these disagreeables cheerfully as incidental to our vocation than to give the public reason to suppose that they are entitled to disturb our rest for a payment of sixpence more or less.

It may not be out of place to quote the changes which have taken place in the hours of closing in this neighbourhood during my recollection, as one instance among many of what has been accomplished since that misty period spoken of by your correspondent as "about thirty years ago," when we, like most of our fraternity, kept open shop till 11 p.m. daily, Sundays included. The first amelioration of this state of bondage was brought about by the unprecedented agency of our customers, who held a public meeting and summoned us to mend our manners. We, thereupon, agreed to close at 8 p.m. in the summer, and 9 p.m. in the winter, but soon found that it was more convenient to adopt one uniform hour all the year round, and that the earliest. About two years ago we agreed to further limit the hours of business by closing at 7 p.m. which is as early as can reasonably be desired by those who expect to make a livelihood by retail trade; and I am not aware that the present arrangement has occasioned inconvenience either to ourselves or to the public. Increased activity in business during the shorter hours will naturally be expected from assistants, and they should not fail to evince their appreciation of the privilege by a willing response to the call.

I was much struck recently by the evidence of similar progress in the west end of London. Formerly the streets were enlivened to a late hour by the glare from the windows of the gin-palace, the tobacco shop, and the pharmacy. In these favoured quarters, if not elsewhere, the undesirable association is now happily dissolved, and Gin and Tobacco are permitted to hold court alone. It may confidently be hoped that the boon will rapidly extend to districts not yet reached, and that pharmacists will have enough self-respect to cease from imposing a hardship upon themselves and others which the necessities of the public do not demand. The influential London houses have set an excellent example, and it is to be hoped that they will always thus lead the van for the welfare and advancement of pharmacy. The smaller houses must ultimately follow though they cannot lead; for it is the province of the great firms to make the ground for us. The opportunities which early closing affords for scientific improvement and its consequent influence upon the elevation of pharmacy are too obvious to need remark, and though I would be the last to counsel anything which might have the semblance of an assistants' strike, it is evident that these considerations will influence their choice of situations; and, having regard to the alleged scarcity of the supply, this must compel the trade generally to follow the practice of the leading firms.

It is above all things desirable that assistants and masters should pull together in this as in every other respect, but I am not sure that the modern assistant has been equally devoted to the interests of his employer as the assistant of former days. Habits are changed and engagements do not now last so long as they formerly did, not long enough perhaps to develop the old feeling of identity with the fortunes of the house. This may be the reason for the suggestion for which there is certainly some foundation, that "Square" men are not popular with certain employers, and I confess to so far sharing the feeling that I would prefer a zealous assistant without science to a paragon of science without zeal. Is it too much to ask assistants to remember that scientific knowledge is intended to supplement, not to supplant, those sterling qualities without which none can satisfactorily fulfil the duties of life?

RICHD. W. GILES.

Clifton.

IRISH PHARMACY.

Sir,—I have hitherto refrained from entering into a paper controversy on this subject, but my attention having been drawn to a letter in your last week's issue, signed C. H. Hartt, in which truth is so grossly misrepresented for the sake of shop, I cannot refrain saying a few words in reply.

In the first place this gentleman appears to ignore the existence of the Irish chemists and druggists; he graciously permits them to retain what he considers the humbler grade—viz., "druggists;" but if they are entitled to this name as being vendors of drugs, much more are they to that of chemists as being both vendors, and also, to a large extent, manufacturers of chemicals, and if I mistake not their knowledge in this branch would contrast very favourably with many who hold the title of apothecary.

Mr. C. H. Hartt glories in the fact that the Irish apothecaries are the only recognized body for the dispensing of medicines, and that they have to undergo examinations and pursue studies which would qualify them for the degree of M.D., which consequently most of them follow, leaving the pure pharmacist almost extinct; consequently the necessity for immediate legislation on the subject which we now seek. The next item of valuable information in Mr. C. H. Hartt's letter is that "the druggist's shop is a kind of general store, where goods of every description can be purchased—drugs included; but whether the druggist's knowledge thereof would even meet the requirements of the Minor examination I very much question."

Now, with regard to this sweeping assertion, I wish in the first place to say that his description of what he calls "the druggist's shop" is not applicable to the Irish chemists and druggists' shops, in which "every description of goods cannot be purchased." But supposing the description to be true, it will also be true of the larger apothecaries' establishments, including the Apothecaries' Hall, but with the addendum of "prescriptions compounded;" but to apply the latter portion of the sentence to this respectable body of men I will require, with your leave, to paraphrase or perhaps alter it a little, I think the following will be about correct:—"But whether the employers, including the compounders, could pass any kind of examination is a matter of doubt, at least, if the following were put as a test question of their competency:—Decide the difference between carbonate of ammonia and cyanide of potassium."

While on this subject I may mention that as far as my memory will carry me I can say that no accident to the public has occurred in Ireland through the ignorance or incompetence of any chemist and druggist, or their assistants. Perhaps Mr. C. H. Hartt can inform you if he can say the same for the apothecaries. With regard to his humble suggestion "that the Apothecaries' Hall as a medical body should cease to exist and turn its attention to pharmacy only;" perhaps if Mr. Hartt used his influence with that worthy corporation he might be able to accomplish his wish, but I fancy the apothecaries consider themselves quite as competent as Mr. Hartt to manage their own affairs, and I think if he would take a hint it might be better for both his own interests and those of the public if he would mind his.

One more word and I have done: it is with reference to Mr. Hartt's want of visionary instinct in "not seeing why the Irish druggists should expect to derive more benefit from the Pharmacy Act than the humblest shop-keepers." I can only attribute such a remark to the grossest ignorance or wilful blindness, and I should be making little of the common sense of the readers of your valuable Journal to say another word on the subject. Apologizing for the trespass on your space, I am, etc.,

WILLIAM HAYES,

Hon. Sec. to the Chemists and Druggists' Society of Ireland.

12, *Grafton Street, Dublin,*
March 17, 1875.

THE ADULTERATION ACT.

Sir,—Permit me through your columns to correct an erroneous report, which appears in a monthly contemporary, of a remark which I made at the meeting of the Social Science Association last week.

I am reported to have said that "The Council of the Pharmaceutical Society wanted to encourage adulteration and I wanted to discourage it."

What I intended to convey was—that I could not have joined the deputation which went from the Council of the Pharmaceutical Society, because I understood they intended to object to the erasure of the word "knowingly," which would, in my opinion, tend to promote adulteration.

The difference between the two statements is important.

I distinctly object either to the retention of the word "knowingly," or to the substitution of the word "fraudulently," in its place, on the ground that either of them would render the Bill of no avail in checking adulteration.

G. W. WIGNER.

79, *Great Tower Street, London, E.C.,*
March 18, 1875.

Sir,—In your last issue appeared a report of a recent meeting of "The Association of Chemists and Druggists of Wolverhampton and District."

In an address delivered by Mr. Wentworth Lascelles Scott, the official analyst, reference was made to Mr. Sclater-Booth's Bill to regulate the sale of food and drugs; and in which one great fault was pointed out—"that in convicting any tradesman of certain offences there specified, the magistrates were permitted no discretionary power in apportioning the amount of the fine in accordance with the circumstances under which the offence was committed."

Mr. Scott then quoted three clauses under which penalties of £10, £20, and £10, respectively, could be inflicted, and remarked, "In each case the magistrate had no option, if the offence were proved, but to inflict the full penalty; that he thought a great hardship."

A lengthy discussion ensued and a resolution was passed:—

"That in the opinion of this Association, it is expedient that the fines imposed for offences under this Act shall not be uniform, as proposed, but shall be left to the discretion of the magistrates, as at present, the maximum penalty being named in the Act, but that a lower penalty may be imposed."

Had Mr. Scott, or the gentlemen taking part in the lengthy discussion, read the Bill before discussing it, they would, in clause 20, have found that:—

"Every penalty imposed by this Act shall be recovered in the manner prescribed by 11 & 12 Vic., c. 43, and 'may be mitigated according to the judgment of the justices;'" the term "justices" being previously defined as including "any police or stipendiary magistrate invested with the powers of a justice of the peace."

The inherent defects in the Bill, as it at present stands, must insure its rejection, and it is quite unnecessary to criticize and condemn clauses that any one, reading it, must know form no part of it.

THOS. PAYNE, Sec.

Anti-Adulteration Association Limited.
6, *John Street, Adelphi, W.C.*
March 15, 1875.

Sir,—Having read so many reports in this Journal in which respectable chemists have been brought before the magistrates for selling drugs not up to the microscopical standard, may I ask why grocers, who sell numbers of our drugs, including "Sulp. Præcipt.," at a lower rate, and much inferior in quality, should not be visited by the same authorities?

JUSTITIA.

[*⁎* Undoubtedly grocers who are in the habit of selling certain drugs are as amenable to prosecution if they sell them in an adulterated state as chemists and druggists are. We would suggest that it is possible for any person possessing evidence of such a practice to set the law in motion against the offender.—ED. PHARM. JOURN.]

MILK OF SULPHUR.

Sir,—Is it not at least possible that a similar mistake is being made about the milk of sulphur as the ancient philosophers made over the famous problem—why the weight of a vessel of water was not increased by the immersion of a living fish?

It may cause a smile among the knowing ones, and yet by your permission I will venture to ask the question—Have the medical properties of the sulphate of lime ever been investigated? Lime combined and uncombined (lime-water with milk), as well as sulphuric acid combined and uncombined, is frequently given medicinally: why may not the sulphate of lime be sometimes beneficial?

Attempts to decompose it have been commercial failures, but may not that wonderful laboratory, the human stomach, with its adjuncts, be enabled to separate its elements and to use the beneficial and to eject the detrimental. *A priori*, this may seem the more probable when we reflect on the enormous tasks we sometimes impose on our stomachs. Few chemists probably, except those of the "Veritas" tribe, can frequently indulge in what may be called a jolly good dinner, but when such a luxury is our privilege, is it not worth a moment's consideration, what an awful task we impose on the analytical attributes of our stomachs, to sift out nutriment from the heterogeneous mess gulped into them in a few minutes? What a power of endurance is shown by some human stomachs year after year! Surely it is not so very unreasonable to suggest the possibility that so powerful an organ may contrive to get some good even out of sulphate of lime, especially when presented to it in the condition in which it exists in the milk of sulphur.

May I also ask on what grounds stand the reputation of any medicine? Does not quinine, for instance, own its high reputation to observation, experience, and testimony? and is it not through the working of the same triad that tons of milk of sulphur are sold annually? I mean sulphur with calcium sulphate, and I contend that, at least in most country trades, if such milk of sulphur be not supplied the customer does not receive what he desires and expects to have. For instance, a farmer's wife on way to market tells a neighbour her children have a "breaking-out" or a "rash," the ready prescription is: "Give them milk of sulphur, it is the best thing in the world for them." Here we have the result of the "observation, experience, and testimony," which, as observed, gives all medicines their more or less deserved repute. The mother goes to her usual chemist, and if she does not get the old-fashioned milk of sulphur she does not have the medicine prescribed for her.

I say the popular reputation of the medicine has been formed on experience of the old article, and the chemist who sells in such cases the sulphur præcipitatum, B. P., sells an article which is not asked for, or intended.

Again, I ask, would it not be more philosophical practically to investigate the virtues of a popular remedy sold by the ton, although no philanthropic professor spends £20,000 a-year to trumpet aloud its virtues, than without any examination to condemn it *ex cathedrâ*?

Many medical men have made their own frames and the persons of their friends the basis of experiment with far more dangerous and active substances, especially with the poison alcohol. As the late Dr. Lankester said, in a discussion on a paper of the late Dr. E. Smith, "The public ought to be very much obliged to the abstemious and persevering doctor, for he not only got drunk himself before breakfast for the benefit of the public, but persuaded some of his friends to do the same."

The operation of sulphur is so gentle that its effects may be submitted to without much personal inconvenience, and surely it would be worth while practically to test the operation of such a popular remedy as sulphur with calcium sulphate in a similar way.

W. SYMONS, F.C.S.

Barnstaple, March 15, 1875.

SYNONYMS.

Sir,—I fully agree with "J. T. C." respecting a book of synonyms, and believe that one of a small and convenient size would find its way into nearly every chemist's shop and into many an assistant's and apprentice's pocket, and that its sale would amply repay the time, trouble, and expense of the compiler.

T. F. H.

London, March 13, 1875.

British Pharmaceutical Conference.—One of the Honorary General Secretaries of the British Pharmaceutical Conference informs us that the Association now numbers upwards of 2700 members, and that since the issue of an appeal some eight months ago, no less than 850 pharmacists have become candidates for membership.

H. A. H.—The Pharmacopœia test is sufficient for the detection of the presence of carbonate, and descriptions of other tests will be found in any manual of analytical chemistry.

"*Registered.*"—According to sect. 1 of the Pharmacy Act it is "unlawful for *any* person to sell or keep open shop for retailing, dispensing, or compounding poisons," unless such persons are registered under the Act, and conform to such regulations as to the keeping, dispensing, and selling of such poisons, as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council.

R. J. M.—The second equation represents the reaction that takes place.

A. Warren.—We agree with you that, besides being otherwise inaccurate, the use of the words Oleum Tempus as equivalent to Oil of Thyme is an amusing instance of the manner in which "the nominative and genitive cases of Latin words are sometimes confounded."

T. F. H. is thanked for his lines on "My Sunday In."

"*Devonian.*"—Blaine's 'Outlines of Veterinary Pharmacy.'

J. Lawrie.—We find that, as you state, in the proportion of the ingredients ordered there is not nearly sufficient fluid to keep the salicin in solution. Squire gives the solubility of salicin as 1 in 28.

COMMUNICATIONS, LETTERS, etc., have been received from J. Whitfield, C. Lowe, J. A. Cope, H. Brown, J. C. McMechan, Gallois, A. Ellis, Mr. C. Heanley, J. B. S., G. H. B., Z. O., "Ranunculus," "A Notting Hill Chemist."

ESSENTIAL OIL OF CHERRY-LAUREL.*

BY WILLIAM A. TILDEN, D.SC. LOND.

It has long been known that the fragrance of cherry-laurel water is due to the presence of an essential oil the properties of which agree so closely with those of the essential oil of almonds as to sanction the general belief in a corresponding similarity of composition. Nevertheless, so far as I can ascertain, this substance has never been submitted to a systematic examination, and this view, however probable, is therefore supported by but little direct evidence. An opportunity of studying the properties and composition of the essential oil of cherry-laurel presented itself a few months ago in a kind offer by Mr. Umney of a large specimen amounting to about two and a half fluid ounces. This was the product of the distillation, in August last, of 300 pounds of the leaves and represents about ·05 per cent. or 1 part from about two thousand. The essential oil thus obtained is, of course, merely that portion of the entire yield which separates during repose from the saturated distilled water *(Aqua Lauro-Cerasi)*, the latter being the primary object of the operation.

In a letter to me on the subject, Mr. Umney adds his opinion that by fractional redistillation of the water the product might have been increased to double this amount, but not more.

The oil, as I received it, had a pale yellow colour and held in suspension a few crystals, probably consisting of benzoic acid. In odour, it resembled essential oil of almonds with, however, a decided flavour of the leaf which gave it a character quite peculiar. Its specific gravity was found to be 1·0615. Tested qualitatively, it gave abundant evidence of the presence of prussic acid, but no attempts were made at a quantitative estimation of this constituent. Mr. Umney represents† the proportion of prussic acid present in the oil at less than 2 per cent., but there can be little doubt that it would be somewhat variable.

The further examination of the oil was conducted in the following manner. About two-thirds of the sample were shaken up with an excess of a strong solution of acid sulphite of sodium, by which all the aldehydic constituents of the oil were dissolved and a very small quantity, between 1 and 2 per cent., of an oily substance containing some brown resin was left. The sulphite was crystallized out from the aqueous solution, and then distilled with excess of sodium carbonate. In this way an essential oil was obtained which after drying by chloride of calcium presented all the characteristics of pure benzoic aldehyd. It distilled without residue between 174° and 178° C., and its specific gravity at 17° C. was found to be 1·0492.

This conclusion was confirmed by a comparison of its "cohesion figure" upon distilled water with that of pure benzoic aldehyd from almonds.

The small amount of the viscid oil left by the bisulphite after repeated treatment with fresh quantities of the solution put any attempt at distillation out of the question. All that could be done, therefore, was to boil it with dichromate of potassium and sulphuric acid, and examine the products of its oxidation. No appreciable amount of volatile products, except a little CO_2, was formed, and the crystalline deposit obtained after this treatment was collected, dissolved in warm solution of carbonate of sodium, and the filtered liquid acidified with sulphuric acid. The acid which then crystallized out was carefully sublimed, and was found to melt at 121° C. There could be no doubt, therefore, that this oxidation product was benzoic acid, with which, moreover, it entirely agreed in appearance, solubility, and so forth. Regarding the nature of the oil from which this benzoic acid was obtained, it is not very easy to speak positively, since the quantity was so small as to preclude further investigation. We may, however, risk the conjecture that, since it was certainly not benzoic aldehyd, it not improbably consisted, at least in part, of the alcohol C_7H_7OH, which stands towards benzoic aldehyd in the same relation as common alcohol to common aldehyd. From the facility with which it is converted into benzoic acid I infer that this portion of the essential oil is probably not a hydrocarbon. The former hypothesis, moreover, derives some slight additional weight from the fact that benzoic alcohol and some of its compound ethers have been recognized in several other products of vegetable origin.

These experiments, therefore, indicate that the essential oil of cherry-laurel leaves consists mainly of benzoic aldehyd, accompanied with hydrocyanic acid (less than 2 per cent. according to Umney), volatile oil, possibly benzoic alcohol (perhaps 1 per cent.) and minute quantities of an odorous resin.

Inquiries I have made as to the nature of the changes by which these bodies are produced in the leaf have not added materially to the general information on the subject. It seems to be agreed on all sides that the volatile oil does not exist ready formed, but is produced by the action of water on certain, at present unknown, principles resident in the leaf, and Mr. Umney seems to lay emphasis on the opinion that this reaction is *instantaneous*.

Hanbury ('Pharmacographia,' p. 227) states that "the leaves may even be dried and powdered without the evolution of any odour of hydrocyanic acid, but the latter is at once developed by the addition of a little water." This interesting observation seems to point to the direction in which further experiments on this part of the subject might be advantageously prosecuted.

THE ACTION OF THE INDUCED CURRENT UPON THE INTRA-CELLULAR PROTOPLASMIC CIRCULATION IN PLANTS.

BY HENRY POCKLINGTON, F.R.M.S.

If Dr. Lindley's chronology be right, the past year (1874) should be red-lettered in every microscopist's diary as the centenary of Bonaventura Corti's discovery of what he called the circulation of the sap in Characeæ and in *Caulinia fragilis*,* a discovery the importance of which has not as yet, perhaps, been fully learned, but which has been of interest to probably every microscopist for the last fifty years. I say fifty years, for it is rather singular that although Corti's discovery appears to have made some little noise at the time, it was soon forgotten (in the lack of physiological botanists), and the rediscovery of the

* Schleiden, or his translator, however, has it 1772, but so far as I know stands alone.

phenomenon by Treviranus in 1807, and by Amici in 1819, came upon the scientific world with all the freshness of a new discovery. Corti appears to have quite mistaken the nature of the phenomenon; indeed, it is not until quite a recent date that it has been recognized as independent of, and distinct from, the general circulation of a plant, and that whatever it may be it is purely intra-cellular. This was shown clearly enough by Robert Brown in his observations on the hairs of Tradescantia in 1831, and by Mohl and Schleiden in their numerous observations on other plants. Other observers, Slack, Meyer, Dutrochet, Varley, Wenham, etc., have described the phenomenon in various other plants, and it has become pretty generally admitted that at least some part of all plants manifest it at some period or other of their history, and that it is in some way or other related to the process of cell life or cell nutrition. The phenomenon has been very variously described, and under different names;* and, perhaps, a brief sketch of the history of the subject, and explanation of the phenomenon, may serve as a suitable introduction to the main subject of this paper. Corti's notion was that the ascending and descending streams were separated by a septum, and that the circulation was a true sap circulation. The existence of a septum was, however, speedily disproved. Others have supposed that there are minute anastomosing vessels on the outside of the cell, and that the circulation takes place in these. This idea, propounded by Schultze, is so highly improbable and so easily disproved by simple observation that we need not wonder that it never gained much ground. Dutrochet's idea that the circulation is due to a galvanic action in which the chlorophyll granules play the part of batteries may be at once relegated to the region of forgotten absurdities. A more plausible theory, propounded years ago and lately revived, accounts for the phenomenon by supposing that the cells are lined with fine cilia, whose constant motion produces the current. Some observers have even asserted that such cilia have been seen by them. This, however, as Wenham has shown, is purely an error of interpretation, due to imperfect illumination or defective lenses, and the theory is probably not now held by any observer of eminence. Certainly the use of a high power—Powell and Lealand's $\frac{1}{25}$th—has abundantly satisfied me as to the non-existence of cilia, or anything analogous to them. Others have supposed the currents to be produced by alternate contractions and expansions of contiguous cells; whilst a somewhat recent observer, B. Schnetzler, supposes that the ultimate cause is to be found in the chemical action of oxygen, which passes through the walls of the cells, and of which a portion is probably turned into ozone under the influence of light, assisted by currents of electricity passing between the surface of the leaf and the contents of the cell. This idea also may probably be relegated elsewhere. A more plausible theory is that propounded at great length and with great ability by Dr. J. Bell Pettigrew,† in his lectures on the "Circulation in Plants and Animals." Dr. Pettigrew says there can be little doubt that cell gyration "is referable to vital, chemical, and physical changes occurring in the cell contents, but the precise nature of these changes is at present undetermined." He believes that the chief cause lies in physical causes, as absorption and evaporation, exosmose and endosmose, capillarity, chemical affinity, etc. Of these numerous physical agencies he singles out the first four as most important, and has devised some exceedingly ingenious apparatus wherewith to illustrate his theory. One of these pieces of apparatus is shown in fig. 1, copied from

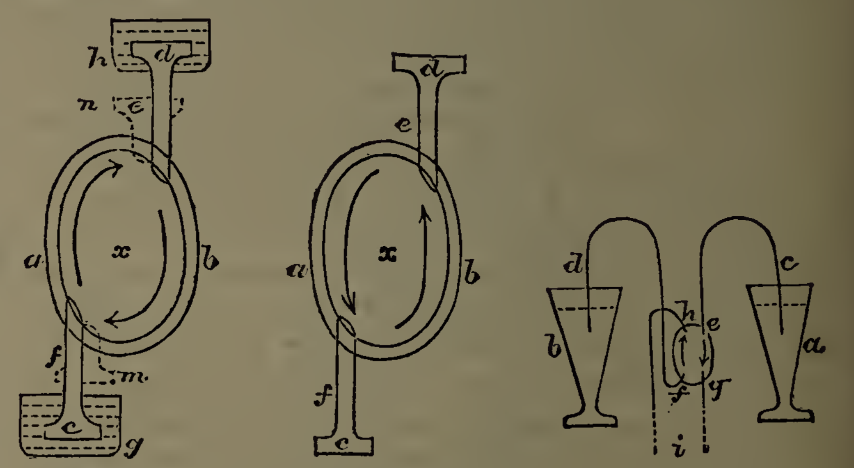

Fig. 1. Fig. 1*a*. Fig. 1*b*.

Dr. Pettigrew's lecture in the periodical cited. There is no doubt that cell gyration could be, and has been, out of the plant, produced by the causes there brought into action, but that the conditions of the experiment obtain in plants is quite another question. It is difficult, for instance, to imagine that the circulation in the terminal cell of a branchlet of Chara is due to any such factors. The general character of the phenomenon in Vallisneria and Anacharis, where the circulation may be right-handed in two or three contiguous cells, then left-handed in perhaps a single cell, amongst other cells whose gyration is right-handed, is also against the simple theory propounded by Dr. Pettigrew.

Probably all that the facts at present known warrant us in saying, is that the phenomenon is purely a vital one, whatever this may mean, and that whatever is inimical to the general life of the plant has a similar influence upon the intra-cellular circulation, and stays it with more or less alacrity. In Chara and Vallisneria the rotation appears to be stopped by the application of a temperature of about 150°F.; before this temperature is reached the circulation begins to show signs of cessation. Prussic acid, acetate of lead, opium, and corrosive sublimate (Pettigrew), iodine, dilute sulphuric and acetic acids and alkalies (Auctor), also arrest it, as does cold below about 50°F. in the case of Vallisneria, and below about 40°F. in the case of Chara. Anacharis appears to be (from some experiments in 1869) much more tolerant of heat and cold than Vallisneria or Chara; but the limits of its endurance have not so far as I know been determined. It is to be noted that different specimens differ somewhat widely in this respect. Mechanical injuries have a very marked effect upon the intra-cellular circulation. The act of cutting the leaf of Vallisneria, or plucking the leaf of Anacharis will generally stay the circulation for a short time, but much of the effect commonly ascribed to these inquiries is really due to a chill caused by transference of the section or leaf to a cold slide, and the circulation rapidly recommences when the slide is slightly warmed, and experiments prove that mechanical injuries are far less potent in arresting the circulation than is sometimes

* Cyclosis, cell rotation, are the most approved.

† *Edinburgh Medical Journal* for 1872–3; since re-published in book form. For further information on the history of the subject see Schleiden's 'Principles of Botany,' Mohl's 'Vegetable Cell,' Henfrey's 'Botany,' Lindley's 'Vegetable Kingdom,' and R. Brown's 'Manual of Botany,' 1874.

said. My own experiments do not confirm the statement in Brown's 'Manual of Physiological Botany,' that jolting or pricking will stop the current. Immersion in milk and thin gum, is said (*op. cit.*) to accelerate gyration in Vallisneria. It will continue in Anacharis, though the plant be immersed in a ten per cent. solution of sugar. (Auctor.)

We have now to consider the behaviour of the phenomenon in presence of an agent known to have a potent influence on vital phenomena generally, the induced current. On this point we meet with contradictory statements in our text-books. Henfrey (Master's ed. of 'Manual') states that electrical currents do not affect it (with this some experiments performed by me in 1868-9 agree—why, will be seen later). Brown ('Manual of Physiological Botany'), on the other hand, states that "a current of electricity stops it, but no sooner is the current shut off than it recommences." To determine between these was one object of my experiments.

The loose use of the word "electricity" by our authors leaves us the choice of the direct galvanic current from the battery, the high tension and rapidly reversed current from an inductorium, or the Leyden jar discharge of frictional electricity. Practically, we are restricted to the former two. It may be best to consider the action of the direct current first, and very briefly; but before doing this a few words are necessary respecting the method of experimentation. In addition to the ordinary battery and conducting wires some form of electrical slide is needful. The simplest is that used by continental microscopists, and consists of an ordinary

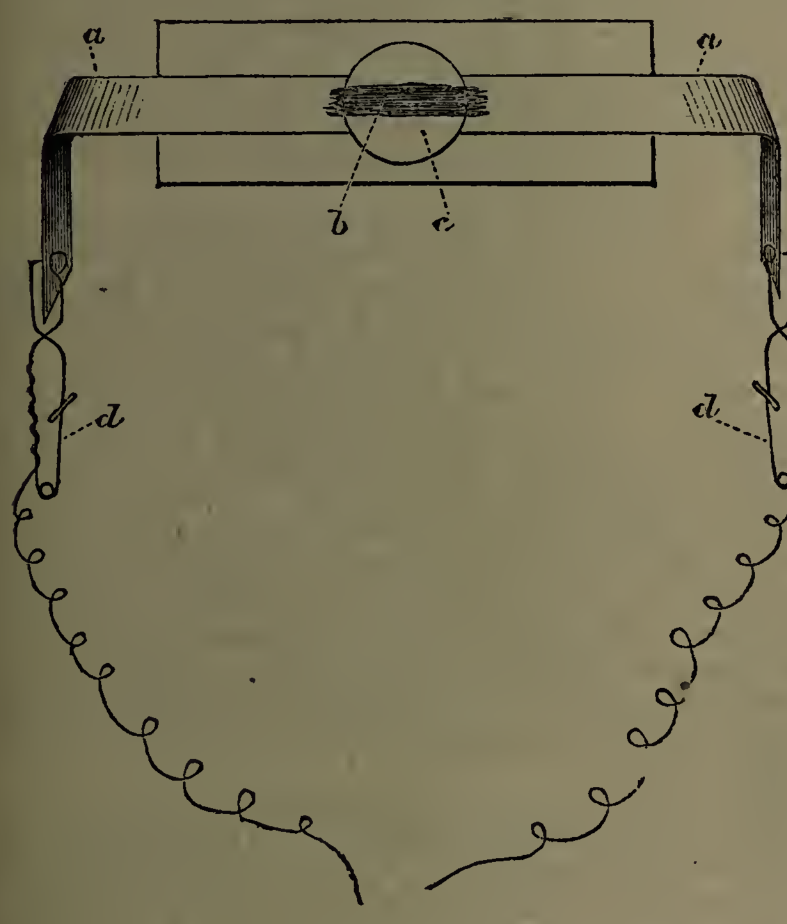

Fig. 2.

glass slip whereon are gummed two strips of metal foil, one from each end to within a short distance of the centre of the slide. The wires from the battery or coil are attached to metal springs, insulated from but attached to the stage. When the slide is in position these springs press upon the tinfoil and complete electrical contact so long as the space between the foils is bridged over by some conducting object. In the examination of Vallisneria we place the portion of leaf in the position shown in the figure, and cover it as usual with the cover. On making circuit the current passed through the whole apparatus, and the effect can be observed by the ordinary modes of illumination. My own use of electricity in microscopical observation is too limited to warrant the expense of special apparatus, and I have modified the stage as shown (fig. 2), which appears to answer all requirements.

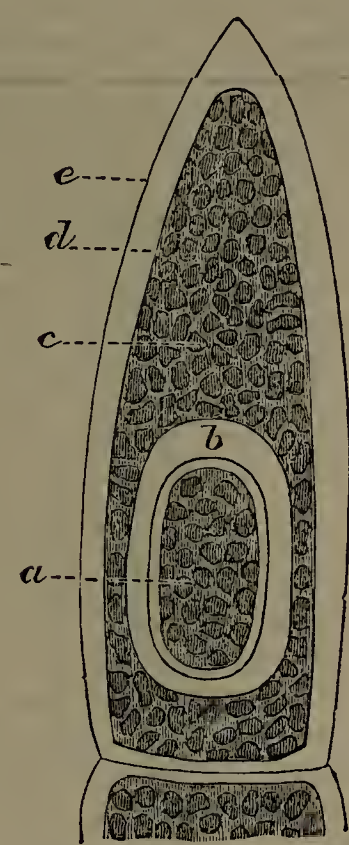

Fig. 3.—Terminal Cell of Chara.

Two thin strips of copper are fastened along the middle of the slip, about a quarter of an inch from each edge, by marine glue, as shown in the figure, and allowed to project about an inch and a half from each end. When the cement is firm these ends are bent at right angles downwards. The wires from the battery are furnished with spring clips (those sold by Baker for mounting answer well if their corks be removed), and are attached to the pendent ends of the slide when the object is in position under the microscope and the slide clamped in its place. If care be taken to have these battery wires well "spiralled" the object may be moved about on the stage, and will be free from vibration with high powers. The circuit must be made and broken, however, either by a commutator or some "break" which will not involve interference with the wires—a mercury break answers as well as any, but I generally use a "short circuit wire" (simply a bridge between the poles of the battery or coil which opens or shuts at pleasure).

Under the influence of the direct current from a single half pint Bunsen cell (exposing about twelve square inches of zinc) the current in Vallisneria is sensibly accelerated for a time, then the protoplasm becomes granulated, and the chlorophyll granules become vacuolated, and the current is gradually brought to a stop. The current from a Daniell cell of the same size does not appear to have any other than an accelerative influence. The circulation in Anacharis does not appear to be influenced by the direct current of low intensity. My experiments on Chara give undecided results, and I am not aware that any experiments have been performed on Tradescantia. My efforts to get a direct current through the interior of the nettle hair have failed (a larger battery power involves heating effects that are objectionable).

The action of the induced current upon the circulation in Anacharis, Vallisneria, and Chara may be divided into two groups, those resulting from the employment of a very low power, and those resulting from the action of a moderately strong current.

The inductorium employed was a small so-called medical coil, without shunt for the reversed current, and without condenser. The battery employed was the Bunsen* and Daniell single cells, already described. The low power was one just sufficient to cause muscular contractions in a young child without being painful to it; the high power was just sufficient to be very slightly unpleasant to a lady. The low power was employed upon Vallisneria only. The results were somewhat contradictory, but the main effect seemed to be, gradual arresting of the current in the larger cells composing the middle layer of the leaf, and temporary acceleration of the current in the more circular cells of the upper and lower layers where the whole cell contents gyrate with greater or lesser rapidity when the leaf is in active growth. The protoplasmic matter in these cells sensibly retracts itself from the cell wall when contact is made, the nucleus becomes more sharply defined, and the whole circulation becomes much more circular and gyratory. Lengthened application of the current leads to degradation of the chlorophyll, and fatal changes in the protoplasm. The action of the current upon these circular cells appears to be that of a true stimulant.

The action of the stronger current has been observed on Vallisneria, Anacharis, and Chara, and with doubtful success on Closterium. Vallisneria is very suitable for the experiment as portions of the leaf may be procured of sufficient length to make a good circuit, and its cells are large, transparent, and the current rapid as well as sharply defined. The terminal cells of Chara answer well if procured from plants grown in water containing little lime. The effects produced by the passing of the currents are exceedingly well marked.† The circulation stops almost instantly, and the margin of the circulating fluid is seen to have suddenly corrugated. If the current be immediately shut off, and it has been only just powerful enough to arrest the circulation, the gyration will recommence in a few minutes. Usually, however, with the current employed in the experiment, it does not recommence, and the protoplasm breaks up, the chlorophyll granules changing in a very singular fashion (at this season of the year; I doubt whether this obtains to so great an extent in the summer when the plants grow more rapidly), by becoming ovoid, with distinct oval slits near their centres. This is probably due to some change in the neighbourhood of the amyloid nucleus of the granules. The current, in short, kills the leaf. The action of the current on the circulation in Anacharis is in all respects similar. In the case of Chara we have similar results with a very singular effect in addition when we deal with young shoots, whose cells, though of considerable length, are still elongating. The circulation stops as in the other plants, and as quickly. If the current be strong we have no other result, but if it be only just powerful enough to arrest the circulation, and we intermit it for a minute, we observe very frequently a remarkable vacuolation of the protoplasmic contents of the cell, then an aggregation of certain of these contents into a spherical mass, like the zoospores in Vaucheria, and the formation on the exterior of this of a hyaline envelope, as in the zoospore of Vaucheria. This does not appear to gyrate or to pass through any changes whatever.

So far as can be ascertained, the action of the current upon the peripheral circulation in Closterium is similar to its action on Vallisneria. The circulation instantly stops, and the protoplasm is contracted on to the surface of the primordial utricle. The active dancing of the particles in the vacuole at each end of the frustule has not been observed to change in any way. It is probably Brownian.

It may now, perhaps, be asked whether these experiments throw any light upon the course of the phenomenon. I fear the answer must be that they throw very little light upon it. They are at most confirmatory of the opinion that it lies amongst those phenomena we at present call vital, because we do not know any physical cause for them.

Explanation of Figures.

Fig. 1 and 1*a* show how the gyration of the cell contents may be produced either by absorption and endosmose, or by evaporation, or by all the three. Fig. 1, *a b*, cell containing viscous fluid; *c d*, absorbing surfaces of cell surrounded by water or other thin fluid (*g h*); *x*, endosmotic currents, which result in gyration (*vide* arrows), are thus produced. To the absorbing surfaces, evaporating ones, as at *e n*, *f m*, may be added. Fig. 1*a* shows how gyration may be effected by evaporation alone. *a b*, cell containing viscous fluid; *c f*, *d e*, evaporating surfaces. The arrows (*x*) indicate the direction in which the evaporation acts.—*J. B. Pettigrew.*

Fig. 1*b* shows how fluids washing opposite sides of a cell in opposite directions will cause the cell contents to gyrate. *c*, *d*, capillary syphon tubes, the extremities of which communicate with water in the vessels *a*, *b*, and with a viscid fluid in the cell *h e f g*, made of glass; the one syphon enters the glass cell at *e*, the other at *f*, capillary tubes being inserted at *g* and *h* to carry off the superfluous fluid (*i*). The fluid within the glass cell gyrates, as indicated by the arrows. This is ascertained by introducing powdered charcoal into the fluid contained within the cell. In the present diagram, the cell has been placed on a lower level than the water contained in the glasses, but it might have been placed as high above the water as it is below it, the gyration within the cell not being produced by the gravitation of the water in the vessels acting through the syphon tubes, but by capillarity alone.—*Ibid.*

Fig. 2.—This hardly requires special explanation; *a a* are two strips of copper or tinfoil; *b* is the section or portion of leaf; *c*, the covering glass which should be kept dry on its upper surface, and not larger than the space between the metal strips; *d*, spring clips. Connection with battery may also be made by allowing the pendent ends of the strips to dip into mercury cups into which the battery wires are led.

Fig. 3.—Diagrammatic representation of completed change in the protoplasm of Chara under certain conditions. *a*, Zoosporelike aggregation of protoplasm with embedded chlorophyll granules; *b*, vacuolar space; *c*, endochrome; *d*, protoplasm of cell contracted from cell wall *c*, *d*; space between *c* and wall *c*, much increased in dimensions by contraction of *c*.

---

* It adds greatly to the comfort of using the Bunsen in a small laboratory if the nitric acid employed be saturated with bichromate of potash.

† A friend to whom I exhibited it (at the Leeds Naturalists' Field Club rooms), likened it to putting a strong "break" on—a very good comparison.

THE OCCURRENCE OF ORGANIC FORMS IN CONNECTION WITH CONTAGIOUS AND INFECTIVE DISEASES.*

BY J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

LECTURE II.

(*Concluded from page* 750.)

RELATION BETWEEN SEPTIC PROCESSES AND THE PRODUCTION OF FEVER.

We must now apply ourselves to the consideration how far the organisms with which we have been occupying ourselves have to do with the processes of disease. As I said, the inquiry must be approached from the pathological side. As naturalists, we may be interested in all the lessons to be learnt from bacteria: in studying the remarkable influence of the conditions under which they originate and grow, in modifying their form, or the question how they come into existence, as it were, out of nothing. But all this is beside the mark; at all events, beside our mark as pathologists. To us, who are concerned about disease, and have its prevention and cure as our ultimate object, the subject loses its interest the moment it becomes unconnected with bodily disorder. Life is short, and the work to be done long and difficult. We must, therefore, keep close to our own subjects, if we wish to make progress.

There are three sorts of diseased processes in which bacteria are supposed to be concerned: the process of fever, certain processes dependent on inflammation, and the various processes of specific infection. The relation of the development of bacteria to the febrile process can be investigated experimentally; for liquids are within our reach that have this property, viz., when introduced in a very small dose into the circulating blood of a living animal, they produce fever—a fever which derives its claim to be so called not merely from its being attended with rise of temperature, but from its consisting of the successive stages which go to make up a febrile accession or attack; viz., a period of latency, a rigour with rapid rise of temperature, followed by loss of muscular power, and a period of decline, the whole process being of short duration—not more than five or six hours, and not being accompanied by any local disease whatever, but being throughout a blood process.

The liquids in question are exclusively derivable from one of two sources; viz. (*a*) products of inflammation, (*b*) products of putrefactive decomposition of blood, muscle, or other animal tissues. I shall speak of them as pyrogenic liquids. Among inflammation products, those of serous and catarrhal inflammations are the most frequent sources. As regards the former, *i.e.*, liquids of serous inflammation, those are most active which are of infective origin, *i.e.*, those of which the producing processes are secondary. Of catarrhal products, there is one which has been used by Senator, and which I have also used myself as a source of pyrogenic material. I refer to the expectoration of the purulent stage of phthisis. From this liquid (which is of course always to be had in any quantity), an extract can be obtained by treating it with two per cent. solution of common salt, which admits of filtration. This extract is always pyrogenous.

It is to be noted first that all of these liquids are apt to contain bacteria; they are not, however, putrid in the ordinary sense; the last mentioned, for instance, retains the peculiar odour of purulent expectoration; and, secondly, that all of them are more active when freshly prepared than at any subsequent period. If, *e.g.*, they are subjected to the temperature suitable for putrefaction, they very rapidly lose their activity, and the rate at which this occurs varies with that of the putrefactive process. This must not be understood to mean that they were not at first in a state of decomposition, but simply that the *pyrogen* (as we may, for shortness, call it, whatever its chemical nature) is a product which is produced at an early stage in the septic process.

But there is, as I have said, another source from which pyrogenous material can be derived, viz., from any animal liquid or tissue in the early stage of septic decomposition. The favourite tissue for the purpose is muscle. If a quantity of muscle be chopped up and placed in water at a temperature of from 60° to 70° F. for a couple of weeks or so, an infusion is obtained which is pyrogenous. The exact period at which it acquires this property depends on various conditions, more than all, on temperature. If this period be allowed to go by, the pyrogenous activity declines, while the obvious signs of putrefaction become more apparent. If the extract be used in the crude state, the result of introducing it into the circulation is often rapidly fatal. The reason of this is that embolism occurs. Little plugs are formed which find their way into the pulmonary artery and produce sudden death.

Even if the liquid be strained, the production of fever (the effect which at this moment interests us) is not the only one which presents itself. Local effects are produced of the class to which I have applied the term secondary inflammation, viz., infective nodules in the internal organs—serous and mucous inflammation. Those animals which are prone to tuberculosis become, in consequence of such an injection, eventually tuberculous, although at the time they may apparently recover from the immediate effects. These effects—all of which must be regarded as in so far embolic that they are dependent on the circumstance that the liquid contains particles of irritating material, which are carried by the blood-stream to various parts of the body, and there prove foci or centres of infective inflammation—have evidently no necessary connection with fever in the sense in which we have agreed to use the word, viz., as consisting in rapid augment of temperature, attended with the characteristic muscular phenomena of rigour, followed by adynamia, and succeeded by a much more gradual decline.

It may, however, be possible by suitable methods to obtain this purely pyrogenic effect without the others. In other words, there may be in muscle extract, at an early stage in the process of putrefaction, a substance which possesses the pyrogenic activity without that of producing secondary inflammation.

Before proceeding to state what others have done, and what I have done myself, in the effort to find such a substance, let me draw your attention to the remarkable fact that no therapeutical agent, no synthetical product of the laboratory, no poison, no drug is known which possesses the property of producing fever. The only liquids which have this endowment are liquids which either contain bacteria, or have a marked proneness to their production.

Further, let me remind you that, whatever effort we may make to discover a disease-producing agent, we must take, both as our starting point and as our guide post, the one fact that we know about it—viz., its pathological action. For our problem is this. In a mixed liquid we have reason to believe that a body exists which has the property of producing fever. Let us suppose that, by the use of appropriate chemical methods, we succeed in separating from it a crystalline principle which forms compounds of definite characters and constitution. To us this is of no value, unless it can be shown that the body so obtained contains the fever-producing property. Or let us suppose that a certain organic form is present, and that, by appropriate methods, we can determine its botanical characteristics, it is of no interest unless it can be proved that the form encloses the property. It was from forgetting this principle that Hallier, whose inde-

* Lecture delivered at Owens College, Manchester; reprinted from the *British Medical Journal.*

fatigable labours as a botanical investigator of the forms of vegetation which he believed to associate themselves with diseased products were referred to in the last lecture, lost his way. He forgot that, in the investigation of morbific agents, pathological experiment and observation are the only safe guides. His results are valueless, not so much because the botanists say they are wrong botanically, but because he went on developing form out of form, without ascertaining as he went along, by repeated experiments, that the clue he was following was the right one.

Let me now return to my own experiments. I will not weary you by detailing the steps by which I was led to adopt my present method, but will content myself with reminding you that the purpose is (assuming that, in all probability, the pyrogenous is separable from what has been called the "phlogogenic" action of the material n question—viz., the septic extract of muscle) to effect his separation by obtaining the "pyrogen" in a convenient form.

The plan is as follows:—The liquid is first precipitated by absolute alcohol. The precipitate is separated by decantation, again extracted with boiling alcohol, and then filtered. The residue, after having been freed from alcohol by placing it *in vacuo*, is extracted with distilled water. The water extract is at once filtered. It is a limpid liquid, which, on injection into the circulation, proves to be pyrogenous. It contains 1·2 per cent. of solids. The dose required to produce a characteristic access of fever in a moderate sized dog is five cubic centimetres, that is, three-quarters of a grain of solid matter.

From this experiment, two conclusions suggest themselves—1. That the agent, of whatever nature, is soluble in water, insoluble in strong alcohol; 2. That it cannot consist of bacteria, or have anything to do with them. Both of these conclusions would be erroneous; and this leads me to what I regard as the kernel of the experiment—viz.: We have an apparently homogeneous and transparent solution which is pyrogenous. Are its constituents really in solution? Is it really homogeneous? If I had not from other experiments learnt that no "animal poison" is really soluble, I should have answered the first question unhesitatingly, Yes. To test it, we apply a method first introduced into pathological investigation by Professor Klebs, of Prague—namely, filtration under pressure through porous cells. By applying this method, I obtain a second filtrate. I test it physiologically, and find that it is not pyrogenic. Pyrogen, therefore, is a substance which passes through filtering paper, but not through porcelain. Further, I find, on microscopical examination, that the first filtrate, although at first it contains no bacteria, is not entirely free from particles; and, if I repeat the examination after an hour, bacteria are present in considerable numbers. If I examine the second filtrate in the same way, even twenty-four hours later, it remains barren. The porcelain has, therefore, removed from the liquid, along with the pyrogenous agent, that on which the development of bacteria depends.

We can scarcely overlook the bearing of these facts on the question of the mode of origin of bacteria; for, considering that bacteria in their ordinary state are destroyed, as Dr. Bastian and others have shown, at the temperature even of boiling alcohol, and that, without reference to temperature, they are inevitably killed by immersion in absolute alcohol, it is clear that our fever liquid as used contains no active bacteria. It is equally clear that it contains that particulate material out of which bacteria spring, for otherwise it could not be deprived of its fertility by filtration. It must, therefore, contain particles which, although they resist alcohol and heat, yet are endowed with a latent capacity of development. I may add that the existence of such particles has been inferred on other grounds by mycologists, who have compared their condition to that of the winter-spores (*Dauersporen*) of the fungi.

GUMS AND MUCILAGES.*

BY M. GIRAUD.

The author has recently communicated to the French Academy the results of a comparative study of some gummy substances which swell in water,—particularly of gum tragacanth,—in which he has sought to ascertain the differences which exist between these bodies and the gums properly so called.

With the exception of gum arabic, the curious composition of which has been indicated by Fremy, the investigation of all the other gums remains incomplete. Although the gums and the organic substances which swell in water present points of physical resemblance, the author states that there exist considerable chemical differences between them, and that amongst the latter class there occur very clearly distinctive characters.

As the result of his researches M. Giraud has found that the mucilaginous substances which swell in water may be divided into three groups. In the first he places gum tragacanth, characterized by the presence of a body capable of forming pectic compounds. To the second belong the mucilages—containing no pectic principles—which are rendered insoluble in water by the weakest acids. This group is represented by the mucilage of the quince, which contains a considerable quantity of cellulose (20 per cent. of the dry mucilage) that can be isolated by the prolonged action, with heat, of acids, or even concentrated alkalies. The third group comprises the mucilaginous bodies—devoid like the preceding of pectic compounds—which are not precipitated by dilute acids, but are transformed rapidly by heat into a substance comparable to dextrine and a saccharine substance.

These different bodies have the common property of becoming transformed under the more or less prolonged action of dilute acids and heat into a sugar differing from ordinary glucose. This sugar crystallizes readily, does not ferment, and possesses a more energetic reducing power than glucose; it appears to belong to the class of sugars named by Berthelot "galactoses."

Having established this classification M. Giraud proceeded to the investigation of them successively, commencing the chemical examination with one of the most important, gum tragacanth, the proportion of which he describes as follows:—

Gum tragacanth is very slightly soluble in cold water; it is far from giving, as has been stated, 30 to 50 per cent. of soluble gum. The filtered product is a mixture of different bodies and not a definite principle like arabin. When it is digested in a water bath with fifty times its weight of water, after about twenty-four hours all the gummy substance is converted into soluble gum, having lost the property of swelling after drying. This new substance is not arabin, as has been asserted, but pectin. Submitted to the action of acidulated water (1 per cent.), in a water bath, this gum is modified after two or three hours, becoming entirely soluble. The new product is not arabin, but principally pectin, and combines with alkalies to form pectates and metapectates; it is precipitable by alcohol. The quantity of glucose formed during this action scarcely corresponds to one-tenth of the matter employed.

For the foregoing reasons the author came to the conclusion that gum tragacanth contains more than one-half of its weight of a pectic principle insoluble in water, which appears identical with that named by Fremy pectose, and exists in the utricular tissue of fruits and roots.

These facts being established the author proceeded to the preparation of some pectic acid from this source. For this purpose some tragacanth was digested with fifty times its weight of water containing 1 per cent. of hydrochloric acid in a water bath until dissolved; it was then filtered and excess of baryta water added. The

* *Comptes Rendus*, vol. lxxx, p. 477.

precipitate, which formed slowly, was pectate of baryta. When of a suitable consistence, this was washed, suspended in water and treated with excess of hydrochloric or acetic acid, which left a precipitate of pure pectic acid. As the result of numerous determinations it was found that by this method about 60 per cent. of pectic acid can be obtained from gum tragacanth. Some analyses of the pectic acid so produced, and of the pectates of lead and baryta prepared with it, gave results which agreed closely with the numbers obtained by Fremy in his investigation of pectic acid obtained from fruits.

Having thus ascertained the nature of the principal compound contained in gum tragacanth, the author proceeded to ascertain the percentage composition of the gum, which he found to be as follows:—

Water	20
Pectic Compound	60
Soluble Gum	8 to 10
Cellulose	3
Starch	2 to 3
Mineral Matters	3
Nitrogenous Bodies	traces.

This result, he considers, establishes sufficiently clearly the chemical constitution of gum tragacanth, and the characters which distinguish it from other gums.

THE EXPLOSIVE SUBSTANCES BILL.

A Bill to amend the law with respect to manufacturing, selling, carrying, and importing gunpowder, nitro-glycerine, and other explosive substances has been brought forward in the House of Commons by the Home Secretary and read a first time. It is of considerable length, and it will affect the storing, dealing, etc., of a large variety of substances, since the term explosive under the Bill is, according to clause 3, to mean gunpowper, nitro-glycerine, dynamite, gun-cotton, blasting powders, fulminate of mercury or of other metals, coloured fires, and every other substance whether similar to those above mentioned or not, used or manufactured with a view to produce a practical effect by explosion or a pyrotechnic effect. It is also to include fog-signals, fire-works, fuzes, rockets, percussion caps, detonators, cartridges, ammunition of all descriptions and every adaptation or preparation of an explosive as above defined. By clause 102 it is further provided that Her Majesty in Council may extend this definition of explosives to include other explosives also.

The Bill is divided into four parts; the first part deals with the law relating to gunpowder; the second with the law relating to other explosives; the third with the administration of the law; and the fourth contains certain supplemental provisions, the order of legal proceedings, exemptions, and definitions.

The first part commences with the subject of the manufacture and keeping of gunpowder. By clause 4, every part of the process of the manufacture of gunpowder —except for the purpose of chemical experiment and not for practical use or sale—in an unlicensed factory, is prohibited under a penalty of one hundred pounds per day. Clause 5 provides that gunpowder in quantities exceeding thirty pounds in weight, except when in charge of a carrier for the purpose of conveyance, shall only be kept in "factories," "magazines," "stores," or "registered premises," as defined by the Bill. Before a new factory or magazine for gunpowder is established, an application for a licence is to be sent to the Secretary of State, accompanied by a plan of the proposed factory or magazine, and details as to the nature of the processes to be carried on, the amount of wholly or partially mixed gunpowder to be kept in stock, and the maximum number of persons to be employed; this proposal the Secretary of State is to be free to accept, modify, or reject. Application has also to be made to the local authority for its assent to the site for the new factory or magazine, and provision is made for the hearing of objections on the part of neighbours or others. Stringent rules are laid down for the regulation of factories and magazines, and the Secretary of State is to have the power to rescind or alter or add to those rules as he may deem necessary. Every occupier of a gunpowder factory or magazine also is to be allowed to make special rules for the persons employed in such establishment, and such special rules are to be enforcible by penalties not exceeding forty shillings after they have received the sanction of the Secretary of State. A factory or magazine for gunpowder used at the time of the passing of the Act is not to be deemed to be lawful unless a certificate in respect of it be obtained from the Secretary of State within six months.

"Store" licences are to be obtained from the local authority, subject to its approval of the arrangements, on payment or a fee not exceeding five shillings. Certain general rules are drawn up to be observed in every gunpowder store, and the construction and situation of stores, and the maximum quantity of gunpowder to be kept in them is to be regulated by an Order in Council.

The 21st clause commences that part of the Bill which relates to the retail dealing in gunpowder, and the registration and regulation of premises in which it is kept for this purpose. It is important to note here that by a clause in Part II. of the Bill all the provisions respecting the storage and sale of gunpowder are, with some modifications that will be mentioned, made to apply to the storage and sale of *all explosives*, as defined in the first paragraph of this abstract. In consequence, therefore, of the importance of this portion of the Bill to the retail dealer who may keep any of those substances in store, clauses 21 and 22 are quoted verbatim.

"21. A person desirous of registering with the local authority any premises for the keeping of gunpowder shall register his name and calling, and the said premises (in this Act referred to as his registered premises) in such manner and on payment of such fee, not exceeding *one shilling*, as may be directed by the local authority.

"Such registration shall be valid only for the person registered, and shall be annually renewed by sending by post or otherwise notice of such renewal to the local authority, together with such fee, not exceeding *one shilling*, as may be fixed by that authority.

"22. The following general rules shall be observed with respect to registered premises:—

"(1.) The gunpowder shall be kept in a house or building, or in a fire-proof safe, such safe, if not within a house or building, to be at a safe distance from any highway, street, public thoroughfare, or public place; and

"(2.) The amount of gunpowder on the same registered premises shall not—

"(*a.*) If it is kept in a substantially constructed building exclusively appropriated for the purpose and detached from a dwelling house, or in a fire-proof safe outside a dwelling house, and detached therefrom, and at a safe distance from any highway, street, public thoroughfare, or public place, exceed two hundred pounds; and

"(*b.*) If it is kept inside a dwelling house, or in any building other than as last aforesaid, exceed fifty pounds, unless it is kept in a fire-proof safe within such house or building, in which case the amount shall not exceed one hundred pounds; and

"(3.) An article or substance of an explosive or highly inflammable nature shall not be kept in a fire-proof safe with the gunpowder, and in every case shall be kept at a safe distance from the gunpowder or the safe containing the same; and

"(4.) Neither the building exclusively appropriated for the purpose of keeping the gunpowder nor the fire-proof safe shall have any exposed iron in the interior thereof; and

"(5.) All gunpowder exceeding one pound in amount shall be kept in a substantial case, bag, canister, or other receptacle made and closed so as to prevent the gunpowder from escaping.

"In the event of any breach (by any act or default) of such general rules in any registered premises,—

"(a.) All or any part of the gunpowder in respect to which, or being in any building, room, place, safe, or receptacle in respect to which, the offence was committed may be forfeited; and

"(b.) The occupier shall be liable to a penalty not exceeding *two shillings* for every pound of gunpowder in respect of which or being on the premises in which the offence was committed."

By clause 30, the hawking, selling or exposing for sale of gunpowder is illegal, rendering offenders liable to a penalty of forty shillings and forfeiture of the gunpowder. By clause 31, all gunpowder exceeding one pound in weight, when publicly exposed for sale or sold, is to be in a substantial case, bag, canister, or other receptacle made and closed so as to prevent the gunpowder from escaping, and (except when the same is sold to any person employed by or on the property occupied by the vendor for immediate use in the service of the vendor or on such property) the outermost receptacle containing such gunpowder is to have attached thereto a label in conspicuous characters, with the word "gunpowder."

The next section of the Bill relates to the conveyance of gunpowder from place to place. It prescribes general rules as to the packing of gunpowder; it makes it compulsory upon harbour authorities to draw up bye-laws, subject to the sanction of the Board of Trade, as to the conveyance, unloading and loading of gunpowder within their jurisdiction; also upon every railway or canal company over whose railway or canal gunpowder is carried to make similar bye-laws; the occupiers of wharves on which gunpowder is unloaded are placed under a like compulsion; whilst bye-laws as to the conveyance of gunpowder by road, etc., are to be issued by the Secretary of State.

Part II., as before mentioned, applies the foregoing provisions as to gunpowder to other "explosives," subject to certain modifications and additions. Of these the following appear to apply to the retail dealer:—

"(5.) Two or more descriptions of explosives shall not be kept in the same store, or registered premises, except such descriptions as may prescribed in that behalf; and, when so kept, shall be kept subject to the prescribed conditions and restrictions; and

"(6.) Where any explosive, other than gunpowder, is allowed to be kept in the same store or registered premises with gunpowder, the maximum amount of gunpowder to be kept therein shall be the prescribed amount in lieu of the amount fixed by Part One of this Act; and

"(7.) The label shall contain the name of the explosive, with the addition of the word "explosive," and if such label is false in any material particular, the person selling or exposing for sale the same, and also the owner of the explosive, shall be liable to a penalty not exceeding *fifty pounds*"

Clause 42 gives power to the Privy Council to deal with the manufacture, keep, importation, conveyance, and sale of any explosive which is of so dangerous a character as to make interference in the interest of the public safety expedient. The next following clauses contain provisions in favour of makers of blasting cartridges not containing within themselves the means of ignition; also in favour of makers of new explosives for experiment, gun-makers making cartridges, owners of mines and quarries as to charges for blasting, and "small" firework manufacturers.

Part III. relates to the administration of the law and provides for the appointment by the Secretary of State of Government Inspectors; it also defines their powers. An Inspector is to have the power of entering a "factory," "magazine," or "store," at all times by day and night; and of entering and inspecting "registered premises" at all reasonable times by day; and he may require and take samples of any explosives he may find there, upon payment for them, and officers are empowered to seize and detain explosives liable to forfeiture. He is to give notice to remedy dangerous practices, etc., under a penalty for non-compliance; but the occupier has the opportunity of appeal to arbitration, provision for the appointment of which is made in a Schedule to the Bill. The section relating to accidents provides that notice shall be sent to the Secretary of State of all accidents connected with explosives causing loss of life or personal injury, and that buildings destroyed by such accidents are not to be reconstructed without written permission from that authority. The Secretary of State is also empowered to order a formal investigation in serious cases.

Part IV. relates to certain Supplemental Provisions, Legal Proceedings, Exemptions and Definitions. Clause 77 authorizes the arrest, without warrant, of persons committing dangerous offences under the Bill. Clause 78 authorizes imprisonment for a period not exceeding three months of a person guilty of a wilful act or neglect endangering life or limb. Clause 79 prescribes a penalty not exceeding £5 for throwing or firing any fireworks in or into any highway, street, thoroughfare, or public place. According to the 90th and following clauses, offences under this Bill may be dealt with either summarily or by indictment. Power is given in certain cases to the offender to elect to be tried on indictment; provision is also made for appeal from a summary conviction to the quarter sessions. Amongst the exemptions from the operation of the Bill are the Government factories, magazines, stores, etc., rocket and fog stations, and certain magazines in the Mersey. Clauses 107 to 112 contain the necessary provisions for the application of the Act, if passed, to Scotland and Ireland.

THE ACTIVE PRINCIPLES OF THE OFFICIAL VERATRUMS.*

A Chemico-Physiological Study.

BY CHARLES L. MITCHELL,

Graduate and Member of the Philadelphia College of Pharmacy.

Part I.—Botanical,

Veratrum Viride.—The rhizoma of Veratrum viride, U.S.
Veratrum Album.—The rhizoma of Veratrum album, U.S.
Sabadilla.—The seed of Veratrum sabadilla, U.S.

Veratrum. *Nat. Order*, Melanthaceæ. *Suborder*, Melantheæ. *Gen. Char.*, Hermaphrodite. Calyx, none; corolla six-petalled; pistils three; capsules three, many-seeded. *Male*, Calyx, none; corolla six-petalled; stamens six; pistils, a rudiment. (Willd.)

Veratrum Viride (U. S. Disp., p. 886), American hellebore, Indian poke, poke-root, swamp hellebore. An herbaceous plant, indigenous to the eastern portion of the United States, and flowering from May to July. The root is perennial, thick, fleshy, the upper portion

* Read before the American Pharmaceutical Association. Reprinted from the 'Transactions.'

tunicated, the lower solid, and beset with numerous rootlets. The stem is from three to six feet high, annual, round, solid, striated, and pubescent; furnished with bright-green leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent, and embrace the stem at their base, forming a sheath for a considerable portion of its length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong lanceolate. The panicle consists of numerous flowers distributed in racemes with downy peduncles. Each flower is accompanied with a downy pointed bract much longer than its pedicel. There is no calyx, and the corolla is divided into six oval, acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments and roundish two-lobed anthers. The germs are three, with recurved styles as long as the stamens. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those on the lower portion fruitful. The fruit consists of three cohering capsules, separating at the top, opening on the inner side, and containing flat, imbricated seeds. This plant is found in low, marshy ground.

Veratrum Album (Woodville's 'Med. Bot.,' p. 754), white hellebore. An herbaceous plant, indigenous to Central Europe, and found in mountainous districts. The rhizome is perennial, about an inch thick, externally brown, internally white, and beset with many strong fibres. The stalk is thick, strong, round, upright, hairy, and usually about four feet high. The leaves are numerous, very large, oval, entire, ribbed, plaited, without footstalks, of a yellowish-green colour, and surround the stem at its base. The flowers are both hermaphrodite and male, existing in very long, branched racemes, and are of a greenish colour. They appear from June until August. The hermaphrodite flowers are without calyces, the corolla consisting of six petals, which are oblong or lance-shaped, veined, persistent, and of a pale-green colour. The filaments are six, closely surrounding the germens, shorter than the corolla, and terminated by quadrangular anthers. The germens are three in each flower, erect, oblong, and ending in short hairy styles, which are crowned with flat spreading stigmata. The capsules are three in number, oblong, compressed, erect, two-celled, opening inwardly, and containing many oblong, compressed, membranous seeds. The male flowers differ from these only in not containing the germens.

Veratrum Sabadilla (Carson, 'Ill. Med. Bot.,' vol. ii., p. 50). An herbaceous plant, indigenous to Mexico. The stem is erect, simple, round, and from three to four feet high. The leaves are numerous, spreading on the ground, all radical, oblong-ovate, obtuse, with eight to fourteen ribs, and glaucous underneath. The flowers are rather nodding. The pedicels are very short, and approximated in twos and threes; those of the fertile flowers eventually becoming turned to one side, those of the sterile flowers deciduous and leaving a scar. The segments of the perianth are ovate, lanceolate, veinless, and of a blackish-purple. The ovaries are three, oblong, and connate-obtuse. The styles are acute and dilated downwards. The stigmata are simple. The capsules are three in number, in form resembling those of the larkspur, and opening at the apex inside. The seeds are three in a cell, imbricated, curved, blunt on one side, sooty, and acrid.

These three drugs belonging to the nat. order Melanthaceæ, genus Veratrum, now included in the United States' Pharmacopœia, present to the eye of a careful student one of the most interesting groups of plants known to science. All belonging to the same genus, and all having a marked similarity in their physical characteristics, they sustain the similitude also in their chemical and physiological relations to each other. Two of them are roots alike in nearly every respect, and differing only in the accidental circumstances of preparation for the market, while the third, although a seed, still bears a strong resemblance to the others in taste, odour, etc., and it is highly probable that the root of this latter plant would show a still more striking resemblance, if brought into comparison with the first two. They are all extremely poisonous, have an acrid and burning taste, and all produce violent irritation when brought into contact with the denuded cuticle.

The theory has long been entertained, that if plants, having nearly the same physical and botanical characteristics differ from each other only in a few comparatively unimportant particulars, their chemical constituents will be found to bear nearly as close a relation, the degree varying according to the general similarity of the plants. This theory has been fully proved in the case of the plants belonging to the nat. orders of the Solanaceæ, Menispermaceæ, Berberidaceæ, etc., and it is partly the purpose of the present essay to demonstrate the correctness of this theory, as far as regards this subdivision of the nat. order, Melanthaceæ. Before going farther, I shall treat briefly of the appearance and physical differences existing between these three drugs, first taking up veratrum viride. As found in commerce, veratrum viride is usually in slices and fragments, generally with the rootlets attached. The rhizoma has apparently been quartered longitudinally, then each piece subdivided into two parts, and thus dried. Very rarely it is found whole, and as far as my experience goes, never without the rootlets. In fact, this is one of the main features which serves to distinguish it from veratrum album. The rhizoma when entire is from one to two inches in length, by about an inch in thickness at its broadest part, tapering from that to a very obtuse or truncated extremity, and closely covered with numerous yellowish rootlets. Externally it is of a blackish colour, obscurely annulated and marked with close set indentations, and generally having a tuft at the top, caused by the remnants of the sheathing leaves. Internally it is of a dirty white colour, very hard and horny when dry, and showing a brown ring under the bark, inside of which can be noticed numerous small, irregular, annular markings. For use the portions of the dried stem and rootlets should be rejected, as they are inert. Veratrum viride has a slight peculiar odour, much more noticeable when moistened, and a bitter, acrid, burning taste, resembling both pyrethrum and aconite. When snuffed up the nostrils, it occasions the most violent sneezing, and applied to a portion of the surface denuded of the cuticle has caused great irritation, and sometimes even nausea and vomiting.

Veratrum album, its congener and ally, bears such a close resemblance to it, that the two can only be distinguished by their appearance in the market; veratrum album being always found whole, and divested of rootlets. The rhizoma is from one to three inches long, by about an inch or less in diameter, cylindrical or in the shape of a truncated cone, and often many-headed. At the top it is tunicated, being the remains of the sheathing leaves. Externally it is of a blackish or brownish-grey colour, obscurely annulated, and marked with numerous whitish scars, where the rootlets have been removed. Internally it is hard, of a dirty white colour, and exhibits the same ring under the bark and annular markings as is noticed in veratrum viride. In its taste it also closely resembles that root, being bitterish and acrid, and it has the same irritating effect on the mucuous membrane and cuticle.

These two roots are so much alike, that when both are divested of their rootlets, it is almost impossible to separate them. I have consulted several high authorities on this subject, and find it is the general opinion, among the best pharmacognosists of this country and of Europe, that there is no reliable method of determining between them, except by the presence or absence of the rootlets. One French author, indeed, attempts to prove a slight difference in the size of the cells in the rootstalk, but his deductions are unsatisfactory and indefinite.

Sabadilla or cevadilla seeds generally occur in commerce mixed with the fruit. This consists of three coalescing capsules or follicles, which open above and appear like a single capsule with three cells. They are three or four lines long, and a line and a half in thickness, obtuse at the base, light-brown or yellowish, smooth, and contain in each capsule two or three seeds. These are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, two or three lines long, wrinkled, slightly winged, black or dark-brown on the outside, whitish within, hard, inodorous, and of an exceedingly acrid, nauseous, burning, durable taste.

Part II.—Chemical.

In order to properly understand the main points under discussion in this paper, it will be necessary to review briefly the different theories advanced as to the composition of these three drugs.

Soon after the publication of Norwood's memoir on Veratrum Viride, Mr. H. C. Worthington (*Am. Journ. Pharm.*, 1838) published an analysis of the root, claiming to have isolated an active principle identical with veratria. His discovery was confirmed in 1857 by Mr. J. G. Richardson (*Ibid.*, xxix, 204), and in 1862, Mr. G. J. Scattergood also examined the root with similar results, finding, however, in addition, that the resin was much more powerful than the alkaloid. Up to this date, all investigators had agreed in pronouncing the alkaloid found in this root to be identical with veratria, but in 1865 (*Ibid.*, Sept., p. 321, and March, 1866, p. 97), Mr. Charles Bullock, of Philadelphia, published a very complete paper on this subject, in which he announced that the alkaloid in question was not veratria, differing from it chemically in not answering to Trappe's test; while the resin which Scattergood found so active owed its power to the presence of another alkaloid, characterized by its insolubility in ether. Dr. George B. Wood, in the thirteenth edition of the U. S. Dispensatory, suggested provisionally for these principles the names of Veratroidia and Viridia. Mr. Bullock's paper was soon after ably supplemented by an essay published by Dr. H. C. Wood, Jun. (*Am. Journ. Med. Sci.*, Jan., 1870), in which the physiological properties of these alkoloids were investigated and described, in comparison with veratria. The subject now seemed closed, but in May, 1872, Dr. Eugene Peugnet, of New York, published, in the *Medical Record*, an elaborate paper on both veratrum viride and veratrum album, in which he asserted that Mr. Bullock was partly mistaken in his discoveries; viridia being a mixture of veratroidia with another alkaloid, which he (Peugnet) claimed was identical with the jervia, discovered by Simon in veratrum album, and possessing only feebly poisonous properties. The paper is very incomplete, the physiological experiments upon which his arguments are mainly based being indefinite and unsatisfactory. The subject created considerable discussion between him and Dr. H. C. Wood, Jun., the main points being left unsettled. In 1874, while making some investigations on verat. viride, I also noticed the presence of jervia (*Amer. Journ. Pharm.*, March, 1874), not being aware until after publication of my paper, that I had been anticipated by Dr. Peugnet. This comprises our knowledge of veratrum viride up to the present time,

Our knowledge of the chemistry of veratrum album is still more incomplete. Pelletier and Caventou, in 1819, appear to have been the first to investigate its chemistry, and found an alkaloid which they called veratria. Simon, in 1837, believed he had found two other alkaloids, one of which he called jervia and the other barytina. Subsequently he transferred the name of jervia to the barytina, discarding it as lime, and recognized the jervia as being identical with sabadillia. Peugnet (see *loc. cit.*) examined the root and found it to contain jervia, no veratria, but instead an alkaloid identical with veratroidia, and ascribed the difference in the physiological action of the two roots to the presence of an active resin in veratrum album, which, when isolated, produced all the poisonous and peculiar effects occasioned by an overdose of the root.

Veratrum sabadilla seeds, according to Pelletier and Caventou, contain veratria, cevadillic acid, a peculiar fatty matter, etc. M. Couerbe discovered two other principles which he named "Le Veratrin," and "Sabadillia; the latter being white, crystallizable, soluble in hot water, and insoluble in ether, and the former a brown resinous matter left after treating impure veratria with pure ether, soluble in acids, and precipitated by alkalies. Simon claims that sabadillia is identical with jervia. Hübschmann confirms the former statement (Couerbe's) as to the separate existence of sabadillia (*Amer. Journ. Pharm.*, xxv, 133). Dr. Mossel ('Sur la Veratrine,' Paris, 1868) considers sabadillia indentical with barytina (jervia). The separate existence of sabadillia seems thus to be involved in considerable doubt.

Some time in the month of December, 1873, I first commenced my investigations on veratrum album, subsequently taking up veratrum viride, and still later sabadilla, thinking that viewed in the light of my previous experiments with the other two veratrums, I might possibly be able to elucidate some points in its chemical composition which had hitherto seemed obscure. In all these experiments the physiological action of the alkaloids was carefully studied as I progressed, by both Dr. H. C. Wood, Jun. (who had previously experimented with the alkaloids prepared by Mr. Bullock), and also by myself. I am also indebted to Dr. Peugnet for some few experiments. The main points to which I directed my investigations were these:—

(1.) What is viridia? Is it a separate alkaloid?

(2). Is viridia identical with jervia?

(3). Does veratroidia also exist in veratrum album, or is there a distinct alkaloid differing from the viride veratroidia?

(4). Does the resin of veratrum album owe its toxic power to an alkaloid like the resin of veratrum viride?

(5). Do the alkaloids exist in sufficient proportion in verat. viride and verat. album to be profitably extracted?

(6). Does jervia exist in veratrum sabadilla?

(7). Are jervia and sabadillia identical?

(8). Is the "Le Veratrin" a separate principle, or only an intimate mixture of veratria and resinous matter?

(9). Do the alkaloids of these three drugs bear a definite relation to each other in their chemical and physiological characteristics?

(*To be continued.*)

EMULSION OF COD-LIVER OIL AND HYPOPHOSPHITES.

The following formula is published in the *Canadian Pharmaceutical Journal*:—

Powd. Gum Tragacanth	½ oz.
Glycerine	3 oz.
Water	9 oz.

Rub the tragacanth with the glycerine, and add the water gradually. To this mucilage add the following solution:—

Hypophosphite of Lime	4½ drs.
Hypophosphite of Soda	2¼ drs.
Hypophosphite of Potash	2¼ drs.
Sugar	¾ lb.
Boiling Water	12 oz.

Make the admixture gradually, with brisk trituration. To this medicated mucilage add the following, as a flavour and preservative:—

Otto Almonds, bitter	10 drops.
„ Cinnamon	5 drops.
„ Canella	5 drops.
Alcohol	6 oz.

The whole will now form a semi-transparent mucilaginous liquid of about thirty-seven fluid ounces in bulk. To this add gradually an equal measure of cod-liver oil, and mix thoroughly. In practice it is advisable to work on small quantities, say half-pint of each, in a number eight mortar. If care is taken the product will be very satisfactory.

The Pharmaceutical Journal.

SATURDAY, MARCH 27, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SALE OF FOOD AND DRUGS BILL.

As the consideration of this Bill in Committee was again deferred from Friday, the 19th inst., until last Monday, it was just possible that the Bill might have advanced another stage before the Journal of the present week was in the hands of our readers. However, this has been prevented by another postponement until Monday, the 5th of April. In the meantime we are glad to note that the amendments adopted by the Government, as well as some others proposed by independent members of the House of Commons will, if carried, materially improve the measure, as first drafted, by rendering it more definite and distinct.

It is to be observed that Mr. SCLATER-BOOTH and Mr. CLARE READ adhere to the use of the word "*knowingly,*" against which such strenuous objections have been made, and we have reason to believe they will continue to uphold the principle of this limitation. If it be considered how much yet remains to be ascertained as to the means of detecting adulteration and distinguishing it from accidental impurity, there is much to be said for the justice of this course. Whatever may be advanced to the contrary, we are disposed to maintain that, in view of the admitted deficiency of knowledge on this subject, the endeavour to stamp out adulteration by the inevitable conviction of retailers would involve an unjustifiable slaughter of innocent persons. We admit readily enough that it is the duty of every dealer to make himself acquainted with the nature and property of the articles in which he deals, but however much we may wish to advance that desirable condition of things, we must, in legislation, adapt our laws to present circumstances. We could name many articles of daily consumption now sold by *unskilled* dealers who have no means of testing their absolute purity save the judgment which every consumer can form as to their being *generally* good or bad. Butter is a notable example of this. Mr. WANKLYN, a very high authority, says he can so prepare a sample of common fat that the best analyst shall be unable to distinguish it from butter. It is well known that large quantities of fat exported from England are again imported as excellent butter. Would the enthusiasts for purity first fine a dealer fifty pounds and then send him to the treadmill for six months for being imposed on in the wholesale market by this commodity? Even analysts themselves cannot say that the fat so manipulated and butter made from the finest cream are not identical substances, for it should be remembered that they may be both the products of one animal. The use of some such material as a substitute for butter made in the usual way seems to be gaining ground, and short of its substitution in trade for the latter the manufacturer who thus finds for an ever increasing population a less expensive substitute, of high quality, for one of the common necessaries of life, is a benefactor rather than a defrauder of his country.

But our readers are more interested in the Bill as it affects drugs, and our opponents may say that at least druggists should be *skilled* traders. We, whose mission it is to promote the highest education in those who practise pharmacy, and the keenest sense of the moral responsibility attaching to them in the exercise of their business, cannot utter a word in contradiction of this. But, here again, we must take things as they are, and although we fearlessly assert that "drugs" (we use the term as interpreted by the Bill to mean generally "*medicine for internal or external use*"), whatever Dr. DUPRÉ may say to the contrary, have, in the last thirty years, been changed from a state of impurity and sophistication to their proper condition mainly by the instrumentality of the Pharmaceutical Society. We know that having to depend on collectors in every quarter of the globe, entirely beyond our control, certain drugs still come into the English market in a condition which would subject dealers in them to prosecution, even though they may be of high quality. We have no sympathy with the man who buys a second rate article and palms it on his customers as the best, but he who selects the best goods the market supplies, pays a fair price for them, and retails as he bought them, should at least be allowed to prove his innocence.

It is this proof of innocence which would be open to him by the retention of the word "knowingly." It cannot for a moment be supposed that the onus of proving *actual knowledge* would be thrown on the prosecutor. It may be granted that the druggist's assumed knowledge should be *presumptive* evidence against him, but that should not be final; he should be allowed to purge himself of the charge of fraud. This is the more necessary when it is remembered for what a multiplicity of acticles a druggist would be imperilled as compared with other traders, and how different those articles are to ordinary food or drink. Accepting for the moment the dictum that all drugs are injurious to health, it would become a question whether any commixture of them could be regarded as harmless, and whether, in truth, some of our contemporaries are not right in urging that drugs and food cannot fairly be made the subject of one rule. On this point, Dr. LYON PLAYFAIR'S proposed amendment of section 3 is good where he requires that the ingredient added to any article *must render the mixture injurious to health* to constitute an offence, and not be merely itself injurious.

The Doctor is not so fortunate in his proposition to shut out from the office of analyst every person who is "engaged in the trade of buying or selling any article of food or drug." It is an undoubted fact that a chemist of the very highest class might fail to possess one of the most important qualifications for an analyst under the Sale of Food and Drugs Bill, inasmuch as he would have no experience as to the natural or commercial condition of the articles referred to him for examination. On this latter point the suggestion offered by the deputation which attended at the Local Government Board a fortnight ago has been adopted, providing an exemption for *unavoidable* admixtures occurring in the process of collection or preparation.

We are glad to see that the Council of the Pharmaceutical Society has not been intimidated by the absurd and unwarranted charges brought against it of encouraging adulteration, but persists rather in endeavouring to make the Bill so simple and reasonable that when passed into law it may be found practicable and effective. A second deputation, consisting of the President, Vice-President, and Treasurer, Messrs. Greenish, Hampson, and Sandford, accompanied by Mr. R. Bremridge, the Assistant-Secretary, and Mr. Barclay, of Farringdon Street, who is watching the Bill on behalf of the compounders and vendors of proprietary medicines, had a further and more satisfactory interview with Mr. Clare Read on Friday, the 19th inst.

THE FARADAY LECTURE.

On Thursday the 18th inst. a crowded meeting of the Chemical Society was held in the theatre of the Royal Institution, for the purpose of hearing the Faraday lecture, which was on this occasion delivered by Professor A. W. Hofmann, of Berlin. The subject selected by the lecturer was "Liebig's Contributions to Chemical Science." Instead of entering into a minute recapitulation of that great philosopher's voluminous labours, he restricted himself to a selection of some few of Liebig's more memorable additions to chemistry proper; but to attempt giving an abstract even of this selection—in itself an elaborate discourse—would fail to do justice either to the memory of Liebig or to the lecturer. We therefore refrain from the attempt in the hope that before long we may be enabled to publish the lecture *in extenso.*

At the conclusion of the lecture the President of the Society presented to Dr. Hofmann the Faraday Medal, the highest honour it is in the power of the Society to confer. In doing so he also paid a graceful and well-merited compliment to the lecturer by remarking, that although the name of Liebig had always been honoured in England for his scientific work there was a further especial reason why this should be the case, since we owed to him the early training of a Hofmann and the direct as well as indirect advantages we have thereby derived. It would be superfluous to dwell here on the fact that we are indebted to Professor Hofmann for having been the chief means of establishing in this country anything like a system of chemical education. It must have been highly gratifying to him to recognize among his audience last Thursday many of his old pupils at the College of Chemistry, who now occupy distinguished and useful positions as professors and otherwise, thus testifying to the beneficial results of his arduous and energetic labours.

AMERICAN OPINION UPON RECENT ENGLISH ADULTERATION PROSECUTIONS.

The *American Journal of Pharmacy*, referring to the numerous prosecutions which have taken place in this country under the Adulteration Act, selects two cases as being especially "curious in some of their features," and as showing to "what annoyances persons may be subjected who endeavour faithfully to comply with the spirit of the law."

The first is a conviction at Wolverhampton for the sale of soda-water certified to contain no carbonate of soda but a considerable quantity of carbonate of lime. Commenting upon these points of the certificate, our contemporary remarks that any American manufacturer of soda water would be liable to a penalty under British laws, particularly if he used hard water.

The other case selected is the milk of sulphur prosecution at Leeds. The analyst is described as "fairly writhing under the searching cross-examination," and as a person who "while admitting that two distinct substances were sold under distinct trade names would insist that they ought to be chemically alike." In conclusion a hope is expressed that if ever an Adulteration of Food Act is passed in the United States, it may be so far perfected by the experience of other countries, that it may not be possible to use it as a "means for annoyance under erroneous preconceived opinions on the part of prosecutors."

THE LATE DR. WELWITSCH'S COLLECTIONS.

The collections made by the late Dr. Friedrich Welwitsch during his exploration of the African Provinces of the Kingdom of Portugal have become the subject of a suit in the Court of Chancery, in which the King of Portugal is the plaintiff, and Mr. Carruthers, of the British Museum, and another, are the defendants. The prayer of the Bill is for an order of the Court to restrain the defendants, as executors, from complying with the terms of Dr. Welwitsch's will, which directs the disposal of the collections in various ways, amongst others, the offer of his "study set" of African plants to the Botanical Department of the British Museum at the rate of £2 10*s.* per century. The plaintiff alleges that it was part of the deceased Doctor's duty, under the terms of the appointment he held from the Portuguese Government whilst engaged in his explorations, to collect in the African provinces botanical specimens and other natural objects, and to make the necessary notes and descriptions explanatory of them, on behalf and for the use of Her Majesty Dona Maria and her successors, so that all such collections, including the notes and descriptions, should become, in the right of the Crown of Portugal, part of the public property of that nation. The suit came on for hearing on Monday last, when Vice-Chancellor Sir C. Hall expressed an opinion that with the aid of a scientific person some arrangement could be arrived at which would satisfy both parties, and with that view ordered the cause to stand over without prejudice to either party.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 18th March, 1875. Professor Odling, F.R.S., President, in the chair. After the ordinary business of the Society, the President called on Dr. Hofmann to deliver the Faraday Lecture, the title of which was "Liebig's Contributions to Experimental Chemistry." After noticing the labours of the great experimental thinker in whose honour this lectureship was founded, he gave a succinct account of Liebig's chief contributions to chemistry, drawing the attention of his hearers to the fact that it was he who first founded the great institutions for chemical education, and that he was not only the discoverer of numerous general methods and the investigator of innumerable organic compounds, but that therapeutics and agriculture were especially indebted to him. The lecture, which was experimentally illustrated by Professor McLeod, took place at the Royal Institution in the presence of His Royal Highness the Prince of Wales, and a crowded audience, among whom were nearly all the leading chemists of this country.

The next meeting of the Society will be held on Thursday, April 1, when there will be read a paper "On the Action of the Copper-Zinc Couple on Organic Bodies, No. VIII. : On Chloroform, Bromoform, and Iodoform," by Dr. Gladstone and Mr. Alfred Tribe.

SOCIETY OF ARTS.

Alcohol, its Action and its Uses.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

Lecture IV.

The position of Alcohol as a food. Its effects on the animal temperature. Hygienic considerations.

The question next for discussion is short and definite. It is included in the three words : Is alcohol food ?

We have studied in the previous lecture the purely physical action of alcohol on the animal body, that which stands apart from the action of food, and we have learned from the study that over the nervous system and over the vascular supply this spirit exerts a specific influence. We now inquire whether the influence ends there, or whether there may be, in addition, either a sustaining, and constructing, or a heat-giving power—that is to say, a force-giving quality in it. If there be, then the simple physical effects are perchance tolerable, or at all events are not sufficient to militate against the advantages which lie on the food side of the question.

It may be well to rest for a moment to consider the position of men and animals upon the earth in relation to the means given to them for their support as living, moving, and, in the higher animals, thinking structures. This position is well defined. The theory that man was made originally out of the dust of the earth is, after all, the most scientific theory that has ever been advanced as to his primeval origin, if the word *dust* be only extended so as to include the actual compound substance of the earth. For in the earth are to be found not only all the elements out of which he is constructed, but even certain of the elements in the same kind of combination as we find them in him. In the earth, water, salts, and organic matter are found ; in man the same are found. The man is in many respects of motion a reflex of the motion of the earth, presenting periodicities of movements, and of movements in a circle in like mode. As if to complete the analogy, this remains true, that the earth yields spontaneously to man, either from herself directly or from the vegetable kingdom which lies between her and man, all the requirements for his existence. Whatever, therefore man invents, though it may seem to be a great necessity, is not a necessity except to those who, being trained to its use, have been led artificially to believe it essential. Thus nature has produced water and milk for man to drink, and they are, in truth, all the fluids that are essential. This lesson, which nature teaches by the rule of provision for the necessities of animal life, is supplemented by many other facts, each equally authoritative. There is ever before us the great experiment that all classes of living beings beneath man require as drink none other fluids except those I have named. We see the most useful of these animals performing laborious tasks, undergoing extremes of fatigue, bearing vicissitudes of heat and of cold, and enduring work, fatigue, and vicissitude for long series of years, sustained by their solid food, with no other fluid than simple water. We see again whole nations and races of men who labour hard, endure fatigue and exposure, and who live to the end of a long and healthy life, taking with their solid sustenance water only as a beverage.

When we turn to the physiological construction either of man or of a lower animal, we discover nothing that can lead us to conceive the necessity for any other fluid than that which nature has supplied. The mass of the blood is composed of water, the mass of the nervous system is composed of water, the mass of all the active vital organs is made up of the same fluid ; the secretions are watery fluids, and if in any of these parts any other agent than water should replace it, the result is instant disturbance of function that is injurious in proportion to the displacement.

When we turn therefore to the use of such a fluid as alcohol under any of its disguises—as spirit, as wine, as beer, as cider, as perry, as liqueur—we are driven *à priori* to look upon it as something superadded to the necessities of life ; to look upon it, in a word, as a luxury. In such sense, it has always been received amongst those nations which have most indulged in it. It is something added to the ordinary life ; something unnecessary, but agreeable. Wine, added to the meal, transforms the meal into a feast ; it is supposed to make glad the heart, but it is never supposed that if the wine were not possessed the life would be shortened. When now we offer wine, it is, by the effect of habit and education, an offering of a thing that is super-necessitous, and in such wise a compliment, an indication of desire or of willingness to be exceedingly hospitable.

All the evidence of a general kind which can be gathered from these observations points to the uselessness, for man, of so artificial an agent as alcohol. But, after all, an assumption so derived may be false. We have already seen that when alcoholic spirit is taken into the animal body it produces in it exceedingly marked effects ; it may therefore, by accident, I might almost say, play in some manner the part of a food and supplement water. Indeed, it is a form of water in which a compound of carbon and hydrogen has replaced hydrogen. Let us, then, ask the question : Can alcohol be in any sense accepted as performing any other part in the body save that physical part which we have considered ? Can it have happened that man, by his invention, has added to nature a food ? And let us answer the question as candidly as the facts of experiment and experience will permit.

Constructive Materials of the Body.

The living animal body is constructed out of a few simple forms of matter which possess, during life, the power of motion. It is, in its living state, a noun and a verb. Whatever helps to maintain it in perfect order of construction, whatever enables it to move of its own mere will and motion, may be considered as a food. The one help gives matter, and mass, the other gives force or spirit to the mass. With the progress of organic chemistry, after the discovery of the art of organic analysis, it soon became evident that what are called foods are divisible into two great classes ; those which supply material or tissue, and those which supply heat or

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

other variety of force. Gradually it was detected that the building foods all contain the element nitrogen as an essential part, and that the force-supplying foods are free of nitrogen, are hydrocarbons, substances that will undergo combustion by oxidation, and thus liberate force for the motive uses of the economy. So, foods have for a long time been sharply classified as nitrogenous or tissue-feeding, and as respiratory or heat-producing. At the present moment this long-accepted view is undergoing some modification. It is being elicited that the nitrogenous foods are to a certain degree heat-producing, but I need not at this stage enter on the nice question involved. I may safely, for the practical purpose we have in view, let the division of the classes of foods remain as described above.

The nitrogenous foods exist in the animal body in the form of what is called colloidal matter, the word *colloidal* being a term signifying a jelly-like substance. The purest form of this matter is found in the blood in the white, elastic, plastic matter, called fibrine. By repeated washings of a portion of this substance, I have prepared from the blood of the ox, a beautiful specimen of this colloid of the blood. Of a similar colloidal substance the moving muscles are formed. In a fluid state, and permanently fluid at the temperature of the living body, the colloid called albumen forms part of organic structure. Under the names of gelatine and chondrine, a nitrogenous colloidal substance forms the organic matter of the skeleton, of the cartilages, of the sheaths of muscles, of the tendons. The eye-ball is constructed out of a series of colloidal tissues. All the membranes which envelop the visceral organs, and which possess elasticity, are colloidal. The outer covering or skin is colloidal, the nails are the same. Even in the brain and nervous matter there is distributed a colloid. Thus, if we sum up the various parts of the body, we may say that all the active masses of structure are nitrogenous and colloidal.

In combination with this active matter, there are, however, two other material ingredients, viz., water and saline substance. Upon this combination with water the activity of the colloid depends. Upon the saline rest the various kinds of combination of the colloid with the water. In bone the gelatine is combined with a salt, called phosphate of lime, with carbonate of lime, and other salts, in much larger proportion than itself. In fibrine the colloidal substance is nearly divested of saline; but in all parts these three material compounds make up the animal structures.

Lying outside these structures in the natural state, but really as an adventitious formation, is one other animal product, viz., fat; a substance detrimental to the motion of the active parts when present in excess, but at the same time capable of combustion, and of yielding heat by the process.

We have now before us the constructive or building parts of the animal body. Excepting the water, the salts, and the fat, they all contain nitrogen, and they take their specific quality from that specific fact. We know that the source of them is the vegetable kingdom, that they are formed by nature in that kingdom, are transferred from the vegetable to the animal, are not made by any natural process within the animal, have not yet been made by any artificial process known to the chemist, and can therefore only be supplied from the one natural supply.

Alcohol contains no nitrogen, it has none of the qualities of these structure-building foods; it is incapable of being transferred into any of them; it is therefore not a food in the sense of its being a constructive agent in the building up of the body.

In respect to this view there is, I believe, now no difference of opinion amongst those who have most carefully observed the action of alcohol. There is, however, a difference in relation to its action as a fat-forming food. It appears to be on evidence that men and animals beginning, while in a perfect state of health, to take in excess certain fluids containing alcohol become fattened. Notoriously, ale and beer fatten; and in some parts of the country certain animals—calves for instance—are rapidly fattened by the process of feeding them with a mixture of barley flour and gin. But through all these apparent evidences there may run an error. The fattening may not be due to the alcohol itself, but to the sugar or the starchy material that is taken with it. As a matter of general experience on which I have tried to arrive at the truth with as much accuracy as can be obtained, I am led to the conclusion that pure spirit drinkers among men, I mean those who do not mix sugar with the spirit, and who dislike spirit which is artificially sweetened, are not fattened by the spirit they take. This tallies also with the observations on the action of absolute alcohol on inferior animals, for they certainly, under that influence, if they are allowed liberty to move freely, do not fatten.

The question of the effect of alcohol in fattening presents still another difficulty. Alcohol, when it is largely taken, unless the will of the imbiber be very powerful, is wont to induce desire for undue sleep, or at least desire for physical repose. Under such conditions there is an interference with the ordinary nutritive processes. The wasted products of nutrition are imperfectly eliminated, the respiration becomes slower and less effective, and there is set up a series of changes leading, independently of the alcohol as a direct producer of fat, to development and to deposit of fatty tissue in the body. All these circumstances militate against the hypotheses of the origin of fatty material direct from alcohol, nor is there any obvious chemical fact that supports the hypothesis. We understand chemically the transformation of starchy matter into one form of sugar, and we infer that in the animal body sugar is transmutable into fat. We know also that we can transmute sugar into alcohol, but as yet we see no way back from alcohol into sugar; if we did, the difficulty of tracing alcohol into fat would probably be over.

Physiological argument nevertheless lends some countenance to the view that alcohol may, by an unknown process, be transferable into fat. It is true that some confirmed alcoholics who do not wax fat in the ordinary sense of the term, that is to say, who do not fill out with fat, from the separation of fatty matter in their cellular tissue outside the vital organs, do, in certain instances, undergo a process of fatty change within their organic structures. Their muscles, including the heart, become the centres of the degeneration called "fatty," and by the interposition of cells of fat in the minute muscular elements, the activity of the fabric is destroyed, sometimes to a fatal destruction. The same degenerative change may extend also to other organs, to the brain and to such active glands as the liver and the kidney.

At first view it occurs to the mind that here is evidence of effect upon cause. At the same time, it is not so clear that the effect is direct from the cause; for when few proceed to examine into all the data that lie before us, we discover such an absence of uniformity in differing examples of the fatty change that we lose alcohol as the clue to discovery. Some alcoholics truly present the fatty modification of tissue, other alcoholics do not present it, so that alcohol may be in active operation and may neither be promoting the production of fat from other material nor yielding it. Lastly, the fatty change of tissue may progress, in the absence of alcohol, in the tissues of those who altogether abstain.

In conclusion, therefore, on this one point of alcohol, its use as a builder of the substantial parts of the animal organism, I fear I must give up all hope of affirmative proof. It does not certainly help to build up the active nitrogenous structures. It probably does not produce fatty matters except by an indirect and injurious interference with the natural processes.

If alcohol be not a substance out of which the animal tissues are formed, may it not be a source of energy of actual motion; may it not supply the power of doing work? Alcohol, we see, contains two elements that will burn in the presence of oxygen, viz., carbon and hydrogen, and although by their combination already with oxygen in the alcohol a certain measure of their potential energy is lost, they are still capable of combining with more oxygen. This is proved by various experiments. When alcohol is burned, that is to say, when, with its combustible elements, free oxygen combines, there results from the chemical combination a certain degree of heat. The heat produced does not approach that obtained by an equal weight of hydrogen, it is not so great as that produced by an equal weight of carbon, but it is greater than that caused by the combustion of phosphorus, and very much greater than that caused by the combustion of sulphur.

The combustion of alcohol thus spoken of is that active combustion which is excited when a light is brought into contact with it so that its vapour may burn. But it is not actually necessary that such instant active combustion should be set up. If we distribute alcohol over a wide surface in the presence of some chemical substances it will then by its combination with oxygen liberate a greater or lesser degree of heat. If I saturate a portion of paper with alcohol and on that paper pour a little of that finely-divided powder called platinum black, I at once get evidence of heat which may be so active that perfect combustion may ensue. In this instance the alcohol is transformed, as in burning, in great part, nay it may be altogether, into carbonic acid and water, which means the completed combustion. If in place of absolute alcohol, in this experiment, I use alcohol diluted with water, then instead of obtaining the active combination and combustion I get a slower oxidation with the production of substances to which attention has already be given, viz., aldehyd, acetic acid, and volatile acetic ether. In this jar I have in progress these various changes in alcohol produced by the mere exposure of the vapour of alcohol to platinum black damped with water, in the presence of the air.

Parliamentary and Law Proceedings.

Prosecutions undes the Adulteration Act.

Adulterated Pepper.

At the Hanley (Borough) Police Court, on Monday, March 15, Mr. William Cooper, grocer, Hope Street, was summoned for selling pepper as genuine which was adulterated. Mr. C. E. Challinor prosecuted on behalf of the Corporation, and Mr. Ackrill appeared for the defence. Mr. John Wright, one of the borough inspectors under the Adulteration Act, said he purchased at the defendant's shop, on November 17 last, two ounces of black pepper, which he told the defendant was for the purpose of analysis. After he had bought it the defendant said he did not sell it as genuine. Witness told him that it would be delivered to Mr. Scott, the county analyst. It was subsequently handed over to Mr. Scott in defendant's presence. Mr. Scott's certificate was here put in. It was to the effect that the pepper was adulterated with sharp sand to the extent of 6·96 per cent. The sample was further adulterated with wheat, linseed, and other vegetable matter to the extent of 20 per cent. It was so adulterated as to be distinctly injurious to health. Mr. Ackrill said he altogether disputed the certificate, but he should submit that the case must be dismissed, on the ground that the defendant gave the inspector notice that the pepper was not genuine before the sale was made. Mr. Bodley said the majority of the Bench decided to dismiss the case, as the evidence as to the defendant's statement was not so clear as they could wish. Mr. Ackrill applied for costs. Mr. C. Adams said he hoped the next case of the kind which was brought before the magistrates would be brought forward in a clearer manner than this had been. Mr. Crapper expressed his concurrence in the decision. The Bench decided to grant costs.

Adulterated Pickles.

At the same Court, Mr. Holmes, grocer, was summoned for selling a bottle of adulterated pickles. Mr. Fulford prosecuted. Mr. Bamford proved purchasing the pickles from defendant's shop on November 16, and handing them to Mr. Scott in defendant's presence the following day. The analyst's certificate stated that the pickles were adulterated with sulphate of copper to the extent of 3·27 grains to the imperial pound, which made them very injurious to health. The defendant was fined 10*s.* and 3*l.* 4*s.* costs. He complained that he was being punished for another person's offence, the pickles having been sold as they were received from the manufacturer. The Bench told him that he was not fined for adulterating the pickles, but for selling them. They admitted that the Act as it at present stood pressed unjustly on retail dealers, and hoped that in the new Bill the state of things would be altered.

Supposed Poisoning by a Vermin Killer.

An inquest was held at the Derby Hotel, Whitehall Street, on Monday, 15th March, on the body of James Stott, ironmonger, whose death occurred under singular circumstances from the effects of poison.

Charles Bentley Stott, 20, of No. 132, Yorkshire Street, identified the body as that of James Stott, his late father, who died on the 11th March, and at the time of his death was 51 years of age. On the previous Wednesday morning witness went to see if deceased was about to come down, as he usually got up earlier, and he said he was not so well and would stop in bed. Witness's brother said his father had vomited in the night, and deceased continued to vomit till the doctor was sent for on Thursday. On Wednesday morning witness asked deceased if he had taken poison. He replied, "Yes, Charlie, I have tasted it." He further said he was spreading some poison for the mice on his own bread and butter and tasted some of it. He said he could not tell him what possessed him that he should do it. Witness knew deceased got some drink occasionally, and had seen him intoxicated, but he was not so on Tuesday, neither was he in low spirits. He believed deceased's life was not insured.

Henry Bland, surgeon, said he was first called to see the deceased at about half-past seven o'clock on Thursday night last, and found him in bed. Deceased complained of thirst, and pain in the abdomen. His tongue was clean, and the pulse quick and feeble. The abdomen was swollen and tender, and the bowels distended with flatus. The vomiting had ceased but the purging continued. In answer to a question, deceased told him he had been spreading some poison for rats, and that he had taken some on the point of a knife. Witness did not anticipate his death, and gave him some stimulant, and ordered egg and milk in small quantities. Witness was sent for again at a quarter to eleven the same night, but on his arrival deceased was dead. The symptoms were such as would have been produced by the deceased having taken an irritant poison. The bread and butter produced was sent to witness by deceased's son as part of the bread and butter which deceased had spread to poison the rats. Witness could not say without analysis that there was poison on it.

Thomas Edward Bentley, 31, brother-in-law of the deceased, said that deceased was not in the habit of keeping poison for rats.

The jury returned a verdict that the deceased died from the effects of an irritant poison inadvertently taken.—*Rochdale Observer.*

Illegal Sale of Methylated Spirit.

The *Daily News* reports that on the 18th inst., Mr. Charles W. Pierpoint, chemist,* appeared at the Lambeth Police Court, to a summons, taken out by the Inland Revenue authorities, for having on the 28th January, he not being a distiller or rectifier of spirits or licensed by the Commissioners of Inland Revenue to mix and make methylated spirit, sold half a pint of spirit, whereby he rendered himself liable to a penalty of £50.

Mr. Powell, from the Solicitors' Department, Somerset House, prosecuted.

Alexander Sullivan, an officer of Excise, stated that on the 28th January he went to the shop of defendant in the Old Kent Road and asked to be served with half a pint of methylated spirit, which he sold him after putting in one or two drops of camphor. Witness paid 5*d.* or 7*d.* for it, and then handed it to Mr. Lewis, who took it to the laboratory, Somerset House.

The defendant said the witness asked him to serve him with the spirit as a favour.

Mr. Chance said he had rendered himself liable to a penalty of £50. He would, however, impose the mitigated penalty of £12 10*s.*

* There is no such name on the Register of Chemists and Druggists.

Review.

History of the Conflict between Religion and Science. By John William Draper, M.D., LL.D., Professor in the University of New York, and Author of 'A Treatise in Human Physiology.' London: Henry S. King and Co., 65, Cornhill, and 12, Paternoster Row.

For a philosophical treatise on the relations which have been maintained between recognized religion and science, commend us to this book. It stands alone in its treatment of a subject which has ever provoked more hot blows than kisses. Though unique in these days, we believe it to be the precursor of a literature which will be read with profit and pleasure by all large-minded students of human progress, as assisting to remove a pregnant question from the platform of controversial heat to the cooler and calmer ground of deliberation and research. Many writers, on both sides, have professed to discuss the topic for the instruction and satisfaction of more readers; yet has it soon become evident to the latter that their would-be teachers desire not so much to compare facts and evidence that would lead to independent conclusions, as to expound their own narrow views on matters too broad for their grasp, in a manner less logical than sentimental. Our author is far removed from the stand of such writers, though it is possible to discern on which side his interest lodges. His work differs from theirs as does the summing up of a judge from the pleading of a barrister.

The object of the book is thus stated in the preface:—"What I have sought to do is, to present a clear and impartial statement of the views and acts of the two contending parties. In one sense I have tried to identify myself with each, so as to comprehend thoroughly their motives; but in another and higher sense, I have endeavoured to stand aloof, and relate with impartiality their actions. I therefore trust that those who may be disposed to criticize this book will bear in mind, that its object is not to advocate the views and pretensions of either party, but to explain clearly and without shrinking those of both. In the management of each chapter I have usually set forth the orthodox view first, and then followed it with that of its opponents." So far as we are able to judge after reading the entire book carefully through, the endeavour stated above falls little short of success; as we have previously said, Dr. Draper occasionally shows the tendency of his conclusions. In pursuance of his object, after having discussed the origin of the speculative philosophy of the Greeks (the modern congener of this has found expression in the phrase "the scientific use of the imagination"), and the impetus and extension given to experimental philosophy by the conquests of this great people in the East and in Africa, a philosophy which found its aptest and grandest expression in the Museum at Alexandria, he arrays against each other the extreme parties on either side, Romanism and Science.

In describing the respective attitudes of these contending forces, the author gives historical accounts of the conflicts respecting (1) The Doctrine of the Unity of God, (2) The Nature of the Soul, (3) The Nature of the World, (4) The Age of the Earth, (5) The Criterion of Truth, (6) The Government of the Universe. He then treats of the relation of Latin Christianity on the one hand, and of Science on the other, to Modern Civilization. The book concludes with a review of the position recently assumed by the Romish Church towards the governments of Europe, and dwells on the probable consequences of the struggle. In view of the present state of affairs on the continent of Europe, and the indications afforded by our own country, Dr. Draper's affirmation that "ecclesiastical spirit no longer inspires the policy of the world," cannot be received without question. In no country is policy unaffected by ecclesiasticism, asserted more or less directly.

We feel sure that no intelligent reader can make acquaintance with Dr. Draper's book without being led to thoughtful inquiry, and without learning much that is with difficulty learned elsewhere. Apart from the intense interest which intrinsically attaches to the momentous subject, an added interest arises from the wonderfully clear and lucid language in which the author invariably expresses himself. Each chapter is a picture painted by a master, who so disposes the lights and shadows of his diction as to throw into necessary or desirable prominence the realities he would have observed; minor incidents are not gloomed, but enveloped in the secondary softness that best befits them.

Notes and Queries.

RED MARKING INK.—M. Wegler describes (*Pharm. Zeit. f. Russland*) a red ink that can be used for marking linen with an ordinary pen. It is prepared by beating up the white of an egg with its volume of water, straining it through fine linen and then mixing with it some finely powdered vermilion. When the writing is dry a hot iron is passed over the back of the fabric, which coagulates the albumen, and fixes the vermillion in the tissue so that it is not removed by soap, acids, or alkalies.

The Sale of Food and Drugs Bill.

Sir,—In the *Pharmaceutical Journal* of the 20th inst., there appeared a letter from the Secretary of the "Anti-Adulteration Association, Limited," referring to the proceedings of our late meeting. Mr. Payne labours under the disadvantage of being ignorant of what really took place at the meeting in question, with the exception of the necessarily very brief report which appeared in your columns; hence the misconception which apparently induced him so hastily to rush into print.

The lecturer on the occasion referred to, and "the gentlemen taking part in the discussion," were perfectly cognisant of the existence and meaning of section 20 of Mr. Sclater-Booth's Bill. Mr. Wentworth Scott, if our memory serves us right, referred to it somewhat in the following terms:—

"I am aware that later on a kind of half-permission is given to magistrates to reduce the penalties, but this in my opinion would not practically interfere with the obvious spirit and intention of the Bill, which I cannot help designating as, in this respect (*i.e.*, uniform penalties), both unjust and inexpedient."

Mr. Scott considered that what comes out first of all in the working of an Act of Parliament is the point so constantly, and we think rightly, insisted upon by counsel and legal authorities of all grades, viz., the "obvious spirit and intention" of the Act; and it is this which in the main magistrates are chiefly influenced by. Of this general fact we could cite numerous instances, except that we prefer to spare your readers such an infliction. At all events the president, council, and members of this Association after a "lengthy discussion," agreed thoroughly with Mr. Scott as to the necessity for the two resolutions which he moved.

Were the Bill as it is to become law, the magistrates—in that part of the country at least—would certainly go upon what Mr. Scott calls the "Draconian Code applied to Food Legislation," and inflict the full penalty in all cases of adulteration brought before them—whether injurious to health or not—whether in cases of milk, 10 per cent. of clean and wholesome, or 60 per cent. of foul and impure, water has been added; and instead of the principle being affirmed that a *small penalty* should be inflicted, unless for the repetition, or the exceptional gravity of the offence, it may be deemed expedient to award a severer punishment, the very reverse would accrue and the highest penalty would be adjudged as the rule, "according to the obvious spirit and intention of the Act," and it would only be in the most feeble and trumpery cases, and by the most strenuous efforts of a clever advocate for the defence, that the small voiced and apologetic permission to the effect that the full penalty "may be mitigated," *i.e.*, slightly reduced—which appears at section 20, would be acted upon at all.

In the majority of cases too, where the defendant conducts his own defence, this timid mitigation clause would never crop up at all.

The matter is capable of easy amendment by the insertion (in all cases where the words occur) in place of "penalty of," of the words "penalty not exceeding," thus affirming at once the sense of our resolution.

In conclusion, we may state, Sir, that we have now every reason to hope that the spirit of the Bill may be altered in accordance with our wishes, from the exceedingly courteous and favourable way in which our communications have been received by Mr. Sclater-Booth. Mr. Scott was awarded the hearty and unanimous thanks of this Association for the way in which he brought this important matter before us, and we feel sure, Sir, after our somewhat lengthy explanation, that you will agree with us in believing that our resolutions were neither uncalled for nor undeserved.

W. Y. Brevitt, F. J. Barrett, *Joint Hon. Secs.*

The Association of Chemists and Druggists for Wolverhampton and District.

69, *Darlington Street, Wolverhampton,*
March 23, 1875.

Mr. Wigner and the Council of the Pharmaceutical Society.

Sir,—In a leading article of your last week's issue (p. 753), you take the opportunity of referring your readers to a letter from Mr. Wigner at page 759, in which you say "he repudiates the statement he is reported, in the *Chemist and Druggist* of the 15th inst., to have made at a meeting of the Social Science Association," and you further trust that "there may have been a similar inaccuracy," in the same report, of words attributed to Dr. Dupré.

I do not understand from Mr. Wigner's letter that he impugns the accuracy of my report. He says, he "intended to convey" something a little gentler than the expression he actually used can well be reduced to. Before he appears in public again Mr. Wigner had better therefore, curb his rhetoric, or secure an audience of sympathetic analysts alone. Your own pious desire to hear of a "similar inaccuracy" in reference to the report of Dr. Dupré's words, indicates that in this instance your chemical sympathies have overpowered your jealousy for the honour of journalism.

The 'Chemist and Druggist' Reporter.

44*a*, *Cannon Street, E.C.*,
March 22, 1875.

[** Though we are not ungrateful for the good intent of our correspondent's admonition we must remind him that "jealousy for the honour of journalism" should be limited by a wholesome regard to truth and common sense, both of which we consider were violated by the statements reported to have been made at the meeting. Not having been present we cannot undertake to decide whether the blame rests with the reporter or with the speakers.—Ed. Pharm. Journ.]

The Cases of Adulterated Pickles in North Staffordshire.

Sir,—My attention has been directed to an editorial on the above subject in your impression of the 13th inst., in which you unintentionally, while endeavouring to do full justice to the vendors of the said pickles, make an assumption of a not too flattering character either to the analyst or to the prosecution.

As you have evidently been supplied with only half the facts of the case permit me to furnish the remainder. The vendors of the three samples of pickles in question were summoned upon evidence of my certificates, which declared that all three samples were adulterated with "some preparation of, or containing copper," one of them being "grossly adulterated" therewith, and also with sulphuric acid. In all three instances it was decided that the sealed half of the sample remaining in the inspector's (Major Knight's) custody should be referred to an independent analyst, the name of Dr. Thudichum being decided upon by the Bench for two of the samples and that of Professor Attfield for the other one, both sides consenting.

In all three instances the referees absolutely and entirely confirmed the facts given in my certificates; in one—the worst case—Dr. Thudichum reported that the pickles were quite "unfit for human consumption," by reason of the large proportion of copper (which he obtained "in the metallic state") and sulphuric acid therein. In this case a fine of 40*s*. and costs was imposed.

As regards the second sample, the same referee reported that he found it also to be adulterated with copper (which he likewise obtained in the metallic state), but he was not prepared to state that the copper was present in such large proportion as to be materially injurious to health.

In the third case the referee (Professor Attfield) reported that the pickles were adulterated with copper, but, in his opinion, not to such a large extent as to be prejudicial to health.

Under these circumstances the Clerk of the Peace (Mr. M. F. Blackiston) had of course the power of pressing for convictions in both these cases also; but he considered that the ends of justice would be met by his withdrawing the summonses upon costs being paid by the defendants, to whose solicitors this offer was accordingly made, and was duly accepted.

Thus all three samples were proved to be adulterated, one with sulphuric acid and all of them with copper, as certified by me.

WENTWORTH SCOTT, F.C.S., ETC.,
County Analyst.

County Analyst's Laboratories,
Wolverhampton, March 22, 1875.

PHARMACY IN IRELAND.

Sir,—I certainly cannot compliment Mr. Hayes on the tone of his letter in your last issue, and if he wants to enlist the sympathy of the pharmacists in this country on behalf of the Society he represents, it will be advisable for him to be a little more temperate in his remarks for the future.

His allusion in the following words, "Decide the difference between carbonate of ammonia and cyanide of potassium," referring unmistakably to an unfortunate case of poisoning which occurred in one of the establishments of a most respectable firm of apothecaries in Dublin, is, to say the least of it, very questionable, and is far less excusable since his next assertion, referring to the infallibility of druggists and their assistants, is quite contrary to facts.

Within the last three years two or three cases of poisoning through the negligence of druggists or their assistants occurred in Belfast alone, one of which terminated fatally; and no doubt there were others in different parts of Ireland. He remarks that the pure pharmacist is almost extinct in Ireland; this assertion has been so often refuted by other correspondents that it is needless for me to enlarge on it.

Those who live in glass houses should be very careful in throwing stones at other people.

GEORGE CARROLL.

32, *High Street, Bristol,*
March 22, 1875.

Sir,—The burthen and the "refrain" of Mr. William Hayes's reply to my letter of the 9th inst. was wholly undeserved. Yet I do not feel aggrieved; nor need Mr. William Hayes feel alarmed. All things find their due level at the last.

"Hi motus animarum, atque hæc certamina tanta
Pulveris exigui jactu compressa quiescent."

However, to be serious, the "Secretary of the Druggists' Association" has touched upon a matter of which I have myself no personal cognizance, but which in itself furnishes no argument invalidating the position I contended for in my former communication.

CHARLES H. HARTT,
Pharmaceutical Chemist.

March 23, 1875.

Sir,—Having read over the Pharmacy Bill drawn up by the chemists and druggists of Ireland, I beg to offer the following suggestions to those who may take an interest in it. Any Pharmacy Bill framed should define who is or what constitutes a "Chemist and Druggist." No mere fact of selling poisons should constitute one, as the present Bill would include a very wide circle, and in the meantime many parties are selling poisons, such as arsenic, corrosive sublimate, and even cantharides, who are totally unaware of their doses, chemical constitution, antidotes, etc.

To obviate this I suggest that *all* parties who wish to call themselves "Chemists and Druggists" should pass an examination; I do not mean a very severe one, but such as will show that they know what they are dealing in, and only on the poisons. There can be little hardship in this, as a month's reading or a few lessons from a competent person would soon post them up. I would leave the term "Druggist" open to any party that likes to take it, but not to sell any poisons restricted to chemists and druggists. For the dispensing of physicians' prescriptions, I would suggest that only those who pass a proper and fair examination on the subjects needed should assume the title Pharmaceutical Chemist. This is only giving justice to the licentiate apothecary and would not be unfair to those calling themselves chemists and druggists at present.

AN ENGLISH PHARMACEUTICAL CHEMIST IN IRELAND.

Sir,—Mr. Hayes, in his reply to Mr. C. H. Hartt, accuses him of ignoring chemists and druggists in Ireland. I would like if the former gentleman would kindly define what he considers to constitute one, and as he is a prominent member of this body it would have some authority. The mere fact of selling chemicals I should think would not constitute one, and as the manufacture of chemicals is very limited in Ireland that would restrict it to a very few. I even question if one-tenth of those who constitute the Chemists and Druggists' Society would come under it. I hold that the only way to distinguish them is by examination, and this is "the bone of contention."

Mr. Hayes forgets that there would still be a difference between an apothecary and a so-called chemist and druggist, even if they only kept a marine store each. The former would have a qualification while the other's title in the meantime is rather indefinite.

Trusting Mr. Hayes will give us the above information, I am, etc.,

INQUIRER.

Sir,—I have just read in the last issue of your Journal a letter from the Secretary of a trade society in reply to one which appeared in your issue of the 13th inst. regarding the formation of a Pharmaceutical Society for Ireland.

In my opinion the facts stated by your correspondent of the 13th inst. still remain uncontroverted; notwithstanding that this Secretary thinks proper to accuse the writer of "gross misrepresentation."

Now, as your correspondent of the 13th inst. points out, the only recognized pharmacists in Ireland are the licentiates of the Apothecaries' Hall (any others practising pharmacy not only break the law but render themselves liable to a fine), consequently, he is perfectly right in saying that the druggists are incapable of forming the nucleus of a Pharmaceutical Society. They can know nothing at all about pharmacy. How can they, when their knowledge of the subject must have been restricted to the sale of paraffin oil, soft soap, lamp black, etc., etc.? As a matter of course, their idea of chemistry must be equally limited.

It is simply ridiculous to think that such persons are competent to dispense medicines, and it would be obviously most unfair and unjust to place them on an equal footing with the licentiates of the Apothecaries' Hall, who have had, first, to graduate in arts, then undergo a protracted and experienced course of instruction, and a stringent examination in pharmacy, chemistry, botany, and materia medica, for the first half of their diploma, and in medicine surgery, jurisprudence, and midwifery for the second; while those drug-vendors were never required to receive any professional education whatever.

The introduction of the Pharmaceutical Act of 1868, in England, was totally different, inasmuch as that the then existing chemists and druggists were *bonâ fide* compounders of medicine, and as a rule were, at all events, fairly educated pharmacists, but who can say as much for traders who call themselves chemists and druggists in this country? As I said before, it is morally impossible that they could understand pharmacy,—except some who have been unconscientious enough to make up prescriptions in direct violation of the Act of Parliament, and have been in some instances prosecuted by the Hall.

I believe that the cry for the necessity of a Pharmacy Act for Ireland has been got up and greatly exaggerated through the interested motive of these drug-vendors who would be pharmacists.

Surely it is well known, that in Dublin, Belfast, and Cork, and all the large towns in Ireland, there are a sufficient number of licentiates of the Hall, well-educated men and with sufficient skill to meet all pharmaceutical requirements, and I trust the Legislature will well consider the subject and think twice before they recommend the passing of the Bill, promoted by these persons who never had the opportunity of studying or practising pharmacy or chemistry in one of their details, and therefore must be disqualified for the position they seek to occupy.

A MEMBER OF THE ASSOCIATION OF LICENTIATE APOTHECARIES OF IRELAND.

Dublin, March 23, 1875.

Pharmaceutical Remuneration.

Sir,—As a practical man, I am glad to see by the letters of "Veritas" and others that some pharmacists, at least, are giving some little thought to the future, when in the "sear and yellow leaf" of our lives it is but right we should, in quiet repose, enjoy that freedom from strife which, and I say it advisedly, characterizes all those who would emulate our fortunate brother. It is not, however, given to all to thus succeed. Even with the greatest perseverance and aptitude in business, together with the utmost frugality, is it possible in many, many cases to do more than pay rent, taxes, and barely subsist? In corroboration of this statement it is only necessary to look into the returns of the majority of chemists' businesses in London, especially in the suburbs, where a return of from £500 to £1,000 a-year is considered very good indeed, and this sum exists rather as the exception than the rule. It is, however, refreshing to read and hear of those "happy hunting-grounds" in the provinces, where returns of £2,000 and upwards are so readily and certainly made from so small an outlay as £200 or £300. Let "Veritas" put one of his sons in a London suburb, especially a western one, with double the above amount of capital,—which will, by no means, be found too much, especially if the chosen pharmacy is to be fitted in the elaborate way now so generally adopted,—and then let him wait patiently, in the meantime using all the business diligence and astuteness his previous education has inculcated in him and see what the result will be, and how much he will be able to save. If a few years' experience in one of the districts alluded to is of any service, I can fairly say the "puttings by" will probably be nearly nil; for what with high rent and taxes, and the keen competition that always keep our prices down, there is little left for net profits, out of which savings can be made. In mentioning competition I not only refer to the silly suicidal practice that appears to exist in this neighbourhood of opening a chemist's business at every corner of a street, or in any little terrace of shops, advertised by enterprising but selfish builders or agents whose only interest is the certain rent or commission gained, but to the great and growing competition we have to fight against with the drapers and grocers, besides the stores that now exist in many parts of town. A large draper, not a hundred miles from this locality, is selling patent medicines, foreign mineral waters, sundries, and even drugs of all kinds, kept put up in various sized bottles, at ordinary wholesale list prices, such, for instance, as tinctures at 2*d*. per ounce, and 1*d*. for bottle; 10½*d*. for 1*s*. 1½*d*. patent medicines, and so on. And this firm does an enormous and increasing business in these goods, so much so that never a day goes by now without at least five or six customers making remarks upon my charges, observing that they can get the same goods at the establishment above alluded to at the ruinously low charges referred to. The consequence is, the retail is "growing small by degrees and beautifully less," and we have only dispensing left, and when a great part of this is done by medical men, I leave others, perhaps better qualified, to reckon the heavy odds against a chemist ever reaching that El Dorado called independence who essays to commence in a western suburb. My advice, therefore, to those about to commence in such is, like Punch's advice to those about to get married—"don't." "*Verbum sap.*," etc. A Notting Hill Chemist.

What is a "Square" Man?

Sir,—I should like to know from "J. G. C." what he means by a "Square" man, since, unless this term be fully explained, it seems to me quite premature for anyone to take up his very extensive line of argument, and still more so since the illustrations "J. G. C." cites as objections to a "Square" man are applicable in a great measure to the whole body of chemists' assistants and apprentices.

Chas. Shapley.

30, *High Street, Shrewsbury,*
March 15, 1875.

Milk Analysis.

Sir,—As the publication of the various methods in use for the estimation of the valuable ingredients in articles of diet is at the present time of much importance, would you kindly allow me, through your columns, to make known the method which I employ in the estimation of the fat and solids, etc., in milk? It is the result of much working and observation on this point.

The conclusions arrived at by Mr. Edward Lawrence Cleaver, published in your issue of March 6th, are exactly what I arrived at some months ago while working on the different processes for milk analysis. I can, therefore, but feel pleasure that my results do not stand alone against the large number of advocates for those processes involving diametrically opposite bases. Conclusion 2, to the effect that cold ether will not dissolve out the entire amount of fat from milk residue, while it is in a pasty condition, is universally true; but Conclusion 1, to the effect that cold ether will not dissolve out the entire amount of fat from dry residue, does not hold good when circumstances are modified. According to a process, after described, all the fat is abstracted from the dry residue with cold ether, which is proved by carrying on duplicate experiments with hot ether, or by treating the residue left after extraction with potash and acid, and then performing a second extraction.

The following are the principal features in the process, and from experiments, some of which I will enumerate, I prefer it to all others. For the estimation of fat:—Take a small mortar of 3 inch diameter and measure exactly into it 5 c.c. of the milk under examination. Of pure, washed, and ignited sand, add a sufficient quantity to hold all the milk within the interstices. Place in a hot chamber (100° C.). In half an hour the milk and sand will be in such a condition as to admit of a partial trituration. Replace the mortar until the mixture is quite hard, then triturate thoroughly. Bring the mass into a tube blown from a piece of stout German glass of half inch diameter, and wash out the mortar twice with small quantities of pure sand, adding the rinsings to the main portion. Add dry ether, close with cork in preference to glass, and shake up in the cold. Pour the solution directly from the tube through a small filter into a convenient vessel (I use a boiling-point flask, the end of the funnel being drawn out until it passes the side tube). Wash the residue in the tube once with ether, pouring the liquid through the filter. The contents of the tube are then emptied into the filter, and the edges, along with the sandy mixture, carefully washed two or three times with ether. The solution is evaporated, and when a boiling-point flask is used, a current of dry air is drawn over the oil to ensure complete dehydration. It may then be weighed.

The advantages of this method are:—firstly, speed, for although a description indicates complexity, and consequent lengthiness, the evaporations are effected with unusual rapidity; secondly, scientific accuracy, seeing that all the caseous envelopes of the milk fat are thoroughly disintegrated by trituration, in every case giving a higher percentage of fat as compared with results obtained by simple extraction after maceration in alcohol.

The following four triple experiments conducted on two samples of milk from the same cow, at different times of the day, will afford some insight. In every case a larger percentage of fat has been extracted by trituration.

Samples.	By trituration. Direct.	Without trituration. By loss.	Without trituration. Direct.
(1.)	3·15	3·02	2·97
(1.)	3·13	3·05	3.00
(2.)	3·12	3·00	2·95
(2.)	3·10	3·04	3·00

In the determination of total solids, I much prefer to work with sand, as the results are not only arrived at in a shorter time, but in every case they are lower then when simple evaporation to thin layers or to the granulated state is adopted.

My method of manipulation is:—Having ignited a convenient quantity of sand in a porcelain or platinum vessel, take the weight including sand. Weigh out into the dish exactly one gramme of milk. Place in hot chamber (100° C.), and when in a hard, though pliable condition, spread the mass with a platinum wire around the sides of the small vessel. Heat until there is no longer loss in weight. The process generally takes one hour, while the usual process takes three times as long.

Three careful experiments on one sample of milk will be sufficient to show that a lower and therefore truer percentage of solids is obtained by the above method as compared with that by the usual process.

With Sand.	Without Sand.	
1 hour	1½ hours	2½ hours
12·41	12·75	12·61
12·38		12·58
12·40	12·70	12·62

Speed is the great inducement to the adoption of this method, and the fact that there is no sacrifice made on the score of constancy or accuracy, but rather the reverse, is an additional attraction.

In specific gravity determinations, which should always be performed, as they give the means of exactly reducing the fat figures from volume to weight, I employ the very accurate method of adjusting the volume by means of fine tubes of differing capillarity. The apparatus is easily blown from a quill tube. Expand a bulb in the centre of a piece of tube, and close on either side, draw out, taking care to leave one arm considerably wider in bore than the other. Bend the thin arms up and over, outwards, until again in a horizontal position, the bulb hanging between. Place on the thick capillary a graduation mark one half inch from the end, and the instrument is complete. When the bulb is filled completely with any liquid, a few seconds' manipulation with a morsel of blotting paper at the end of the thin capillary will suffice to bring the column of milk exactly to the graduation mark on the opposite arm, when, if constant in temperature, it may be weighed. The utmost accuracy is attainable, and the speed is equal to determination by the float.

At first sight the above methods of manipulation appear to be troublesome. They in reality are not so. From the fact that every point of the process is reduced as far as possible to mere mechanical routine, the mental anxiety towards securing accuracy is much diminished.

The time occupied in an examination is, if anything, less than by the usual methods.

The advantages may therefore be stated as being—firstly, the reduction of the chance of experimental error; secondly, a nearer approach to truth in the actual amount of fat and solid.

G. D. Macdougald.

"Synonyms."

Sir,—Few pharmacists could doubt the ready sale of a book of Chemical, or more correctly speaking, Pharmaceutical Synonyms, provided it is the work of a really experienced man, whose name would be a guarantee to its efficient and exhaustive character.

The form, I would venture to suggest, should be that of an ordinary dictionary, no lengthy description of each article being required, but simply the obsolete name and its present representative, and *vice versâ*, or where necessary the formulæ for its preparation.

A printed letter forwarded to every chemist asking co-operation by supplying any technicalities, would doubtless bring to light many which otherwise might escape notice, and I believe most gentlemen would feel a pleasure in supplying the needed information.

Rebus.

March 23, 1875.

*** In reference to the above subject we have received a communication from Mr. O. D. Owen, stating that he has been engaged for a considerable period in compiling a 'Book of Synonyms,' but that it is yet too incomplete for publication.

Saccharated Calomel.

Sir,—Anticipating some remark would follow from an abler hand than mine I have hitherto held my pen from any observation on the startling paragraph of the presence of perchloride of mercury in saccharated calomel (*Pharmaceutical Journal*, December 26th last, p. 519). I certainly felt rather surprised at such a statement and receive it as purely chemical knowledge. I am also very uneasy respecting using the same, having it in daily use as teething powders for children, and if any of the numerous readers of the *Pharmaceutical Journal* can give me any experience in the use of the same powders for children as to their safety or of the smallest hazard of danger, I shall be glad of the information. At the same time I wish to know if any presence of perchloride of mercury has been detected when calomel is mixed with sugar of milk.

Any correct knowledge of the above will much oblige.

J. B. S.

Physiological Chemistry.

Sir,—It gives me great pleasure to address the editor of one of the leading scientific journals of our time. Truly we live in an age of great enlightenment as regards scientific and analytical research,—one in which the hidden mysteries are dragged ruthlessly before our eyes and the component parts of seemingly intricate compound bodies are laid open to our view and their composition definitely ascertained. So much for the advance in analytical chemistry, and still it goes on with rapid strides, overcoming every obstacle it meets with, and opening new paths for the practitioner of medicine to walk in. But still there are untrodden paths yet to be explored. A brother M.D. in this city (who, by the way, is also a member of the Pharmaceutical Society of Great Britain) is a great enthusiast as regards the proximate analysis of everthing which may lead to the unearthing of anything new in the amelioration of disease, and has had frequent discussions with me in reference to the component parts of diseased structures and the pathological changes which take place in consequence of the alteration of the atomic principles, which by their normal union form the healthy structures of the body.

To make it clearer I will state that any analytical chemist can now tell positively the exact composition of the blood, also the component parts of muscle and of bone. Now, what change analytically speaking takes place when tuberculosis makes itself manifest, or what change takes place in the blood when scirrhus makes its appearance? These are the questions which I think have never yet been answered; but I am satisfied if analytical chemists generally would take the matter in hand and thoroughly investigate all the altered conditions of the atoms, they could supply us with powerful weapons to destroy these "degenerative processes" which are carrying off their tens of thousands yearly, by informing us of the chemical changes which they find by analysis, in those parts which are affected by those diseases.

J. C. McMechan, M.D.

Cincinnati, Ohio, United States,
March 2, 1875.

Absolute Phenol.—A Yorkshire pharmacist writes to state that when lately visiting the metropolis he obtained a sample of this article; but before exhibiting it to friends as the last new thing he fortunately examined it, and found that it was altogether different to what he had expected, it being sulphate of zinc crystals. The said "young man from the country" charitably hopes this was simply a mistake and not an attempted joke.

J. Finch.—Probably the labels would require a stamp, especially if they contained the proposed addition. You are recommended to submit them for the opinion of the Inland Revenue Authorities at Somerset House, who alone can answer your question authoritatively.

F.K.—We believe that up to the present time the lectures have not been published in a collected form.

"*Quintus.*"—*No licence* is required for the sale of quinine wine, if it be made according to the recipe in the British Pharmacopœia and not sold as a proprietary or patent medicine. See *Pharm. Journ.*, Oct. 26, 1872, p. 327.

E. S. V. is referred to the rule respecting anonymous communications.

Irish Pharmacy.—*Errata.*—We are requested by Mr. Hayes to make the following corrections in his letter on p. 759. In col. ii. line 8, *for* "employers" *read* "employees." Line 11, *for* "Decide the difference" *read* "Describe the difference." We have referred to his MS. and find that the words were written as printed last week.

Copies of Prescriptions.—G. H. B. writes in reference to this subject that he considers pharmacists would be consulting their own interests by giving copies gratis, and he states that he has known instances in which a charge has caused great dissatisfaction.

J. P.—The explosion that takes place is not such as you imagine, but is due to the ignition of the hydrogen evolved.

T. Crew.—You will find all the information you ask for in an article in vol. v. of the second series of the *Pharm. Journ.*, p. 33.

Communications, Letters, etc., have been received from Mr. J. Booth, Mr. W. Robertson, Mr. J. Bown, Mr. Atkins, Mr. Pitts, S. G.

THE PRESENCE OF LEAD IODIDE IN SYRUP OF IODIDE OF IRON.*

BY W. A. SHENSTONE.

Some two years since a specimen of syrup of iodide of iron, containing spangles of lead iodide, was exhibited at a meeting of the Pharmaceutical Society by Dr. Attfield, who had it from Mr. Rimmington, of Bradford. A good deal of information concerning the contamination was elicited from some of the members present, but I do not think the matter was much noticed by pharmacists generally, and therefore, having recently met with a case of the kind, I thought it probable that a few words on the subject would not be without interest.

The source of the lead in these cases appears to vary. Mr. Williams, who has met with the difficulty on a large scale, states that in all cases it has been due to the use of impure iron filings, whilst Mr. Umney finds that it only occurs when the iodide is prepared with rough iodine, which sometimes contains lead from having been sublimed into leaden vessels. Obviously the use of pure iron wire and resublimed iodine would remove these causes of trouble, and in the present case these precautions were taken; moreover, the same supply of iron and iodine had been repeatedly used for the purpose, and the solution of iron iodide was prepared in an enamelled vessel, which also had been often previously employed; it appears, however, that on this occasion the mixture of iron, iodine, and water was allowed, by an accident, to become much hotter than usual, and this leads me to think that, under the conditions of the operation, the iodine acted on lead contained in the enamel, and so brought about the mishap. I would, therefore, point out the advisability of avoiding the use of enamelled vessels in preparing iron iodide, if it is intended to apply heat during the process. There are thus three ready means by which lead iodide may get into syrup of iodide of iron, and I wish I could indicate three equally easy methods of getting it out again, but this I am unable to do. Up to the present only one process has been proposed, viz., diluting and decomposing the lead iodide with sulphuretted hydrogen. This is said by Mr. Williams to succeed; but it seems to me that the necessary reconcentration, either by addition of more iron iodide and sugar, or by other means, is a considerable disadvantage, and I have thought it might be avoided by passing the gas into the undiluted syrup kept hot by a water-bath, removing the lead sulphide by subsidence or straining, chasing out excess of sulphuretted hydrogen by a current of carbonic acid gas, and finally warming the syrup with a few fragments of iron wire to remove any hydriodic acid that may remain. I intended subjecting this process to the test of experiment, but unfortunately have not had the necessary time at my command. I have, however, found that all but a very small portion of the lead is converted into sulphide by passing the gas into the hot syrup for a comparatively short time, and therefore feel justified in recommending a further trial of the method, especially as the process by dilution can be just as well resorted to afterwards, in case of the above plan failing.

*Read before the Bristol Pharmaceutical Association, January 22nd, 1875.

A SECOND KIND OF JABORANDI.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

In a recent number of the *Revista Farmacéutica*,* published by the Pharmaceutical Society of the Argentine Republic, Señor Domingo Parodi, gives an account of a chemical investigation by himself of the active principles of jaborandi. Although the drug described by him is not, as he appears to think, identical with the jaborandi of Pernambuco, yet his method of procedure in examining the drug and the results he obtained may be not altogether without interest.

The jaborandi which he has examined is that used by the natives of Paraguay, and is evidently, judging from the botanical description given by him, a species of *Piper*, but it does not, as he suggests, correspond to the *Piper Jaborandi* of Velloso.† According to the author "jaborandi" is a sort of generic name applied to various plants having an acrid or pungent taste, but restricted in Paraguay, in a medicinal point of view, to the *Piper* which he describes. That there may be no misunderstanding as to the plant which Parodi examined, his description is here quoted *verbatim et literatim:—*

"*Jaborandi.*—Suffruticosum, tri-ulnare ramosum, glaberrimum. Caule tereti nodoso inmaculato. Foliis modice petiolatis, usque 9-pollicaria, subcoriaceis s. potius membranaceis, ovatis, opacis; supero oblongo-ovatis, apice breviter attenuatis, basi rotundatis parum inequaliter productis.

"Petiolis super sulcum læviter caniculicatis, non marginatis. Spicæ oppositifoliæ, erectæ, mediocres, breviter pedunculatæ, pedunculis subtilissime pubescens, hermaphroditæ. Bractæ floræ clavate, pressione angulatæ, apice convexæ, margine dense pubescentes.

"Filamenta elongata, crassa, marcescens. Antheræ 2, monothecæ, laterales, apice conniventes, basi divaricatæ, flavæ, siccæ fuscæ, rima laterale. Stylus brevissimus, persistens. Stigmata 3, raro 2, brevia, crassiuscula, divaricata. Baccæ feræ exsuccæ, confertissime, obovato-trigone, albumine farinosa. In sylva, loco humido prope Caacupé."‡

The properties of the Paraguay jaborandi resemble those of Pernambuco jaborandi, being powerfully sialogogue and sudorific.

The former is used for bites of poisonous reptiles, the expressed juice being applied to the wound and a cup of an infusion prepared with the fruiting spikes, leaves or roots, taken every quarter of an hour until copious perspiration ensues.

It is also commonly used for marsh fevers, and generally with a favourable result. Externally it is applied in the form of powder, plaster, or decoction, as a stimulant and detergent.

Being desirous of ascertaining if these properties

* January 1st, 1875, p. 3.

† The plant described by Velloso has four stamens and four stigmas, that described by Parodi has two stamens and three stigmas.

‡ It has before been pointed out that under the name of "jaborandi" several different plants are known in various parts of South America. Leaves of a species of *Piper*, which seem to differ from that above-described, have been imported into England; also a root belonging to some species of the same genus. This root is remarkable for the peculiar persistent salt taste which it leaves in the mouth when chewed. I have not been able yet to ascertain to what species these belong, but the leaves are certainly not those of *Piper Jaborandi*, Vell.

were due to the essential oil alone, Parodi made the following examination of the drug:—

Two kilogrammes of the leaves and spikes, with flowers and young fruits, were macerated for twelve hours in six times their weight of water, and then submitted to distillation.

The first kilogramme of water that came over possessed a pungent and acrid taste, and had an opalescent appearance, with some drops of oily liquid floating upon the surface. This liquid being saturated with chloride of calcium, the greater proportion of the essential oil separated. Its taste was acrid and caustic. A current of hydrochloric acid gas was then passed through the oil, and this produced a crystalline mass similar to artificial camphor. The contents of the retort were then expressed, and the resulting liquid filtered and carefully evaporated to dryness. The extract thus obtained was macerated for two hours with alcohol of 40°, which separated the gummy part. The alcoholic solution was then evaporated, and the residue dissolved in water acidulated with hydrochloric acid, and afterwards treated with pure benzine. The mixture was shaken, the benzine solution separated and then allowed to evaporate in the open air. In this way 2 grammes of an amorphous residue were obtained, which, when redissolved in absolute alcohol, left a little resin, and the alcohol being left to spontaneous evaporation, there appeared in it small groups of interlaced prismatic crystals belonging to the rhombic system. These crystals heated in a tube with soda lime gave off an abundance of ammoniacal vapours. The crystals were easily soluble in amylic alcohol and benzine, but little soluble in dilute acids and in ether. The alcoholic solution is precipitated by phosphomolybdate of soda and by phosphotungstate of soda. This alkaloid has but weak affinities for acids. Sulphuric acid colours it a tawny yellow passing slowly to green. It is fusible at 110° and decomposed at a much higher temperature. The crystals treated with nitric acid give off nitrous vapours and leave a residue of resinous appearance and extremely bitter taste. Gr. 0·50 submitted to analysis gave :—

Carbon	57·30
Hydrogen	5·86
Nitrogen	13·57
Oxygen	23·27
	100·00

One hundred parts combine with 17·5 of hydrochloric acid, giving an equivalent which leads to the formula $C_{20}H_{12}N_2O_6$. The characters of this substance seem to allow of its being placed, under the name of Jaborandine,* in the series of crystalline principles obtained from *Piperaceæ:* viz. piperine, methysticine and kawaine.

THE DETERMINATION OF POTASSIUM AS CHLORIDE OF POTASSIUM AND PLATINUM.†

BY G. KRAUSE.

Probably nowhere is the estimation of potassium by means of platinic chloride practised to the extent that it is in the laboratories of the chemical works at Stassfurt. The author, who is a chemist in Stassfurt, has, therefore, thought it would be worth while to describe the way in which these examinations are made, together with some of those modifications in the manipulation which are carried out in practice, but are more or less left undescribed in the handbooks.

The analysis is conducted in the following manner: the substance to be examined being a potassium chloride, which is an average specimen of the manufactured material, it would consist of about 80 per cent. of potassium chloride, 10 per cent. of sodium chloride, 5 per cent. of magnesium chloride, magnesium sulphate, and calcium sulphate, of the latter two very little, and 5 per cent. of moisture. Sometimes, however, it would be richer in potassium chloride. A larger quantity of sulphuric acid, such as would occur in the manure-salts of this district, must first be removed by barium chloride, using the smallest possible excess of the reagent so as not to cause a useless expenditure of platinic chloride thereby. After the sample has been well pulverized and mixed, a portion of it is dissolved in water. The quantity taken differs, but the best proportion seems to be about 10 grams to 250 c.c. of water. Less of the salt would yield a less exact result through the employment of more water. The solution is filtered to remove mechanical impurities, and 10 c.c. are taken up by means of a pipette, and dropped into a porcelain capsule already fixed in a water-bath. The quantity taken answers to the twenty-fifth part of 10·0 grams = 0·4 gram. The platinic chloride is now added in excess; the mixture is stirred with a glass rod, and evaporated to dryness. The residue is then moistened with a few drops of water, the capsule is quickly cooled and its contents triturated with 2 to 3 cub. cent. of alcohol, 90° to 95°. After standing a little while the liquid is poured upon a filter which, after being dried at 120° to 130° C., has been weighed and moistened with alcohol, there the residue is again washed with alcohol, and the liquid passed through a filter until a drop of the filtrate appears colourless, and no longer gives a chlorine reaction with silver nitrate. The precipitate is now removed by means of a wash-bottle from the capsule to the filter, where it is finally left to drain, and the yet adhering spirit removed by gently drying with blotting paper. The filter is then placed in a drying closet at 120° C. to 130° C. for half-an-hour, and then weighed immediately between tared glasses, pressed together with a clamp. The increase in weight shows the amount of potassium platino-chloride obtained. This multiplied by 0·305 and divided by the quantity employed (= 0·4) gives the weight per cent. of potassium chloride. The factor 0·305 corresponds with the formula :—

$$\underbrace{K_2PtCl_6}_{488\cdot40} : \underbrace{2\,KCl}_{149\cdot00} = 1 : x$$
$$x = 0\cdot305$$

In calculating it as potassium sulphate the figure 0·356 is used :—

$$\underbrace{K_2PtCl_6}_{488\cdot40} : \underbrace{K_2SO_4}_{174\cdot00} = 1 : x$$
$$x = 0\cdot356$$

The quantity of potassium is obtained by 0·159 :—

$$\underbrace{K_2PtCl_6}_{488\cdot40} : \underbrace{K_2}_{78} = 1 : x$$
$$x = 0\cdot959$$

Simple as this operation may appear, and, in fact, is, there are several precautions in the manner of proceeding which have to be observed in order to attain a correct result. In the first place ammoniacal vapours must be avoided, and the formation of platino-chloride of ammonium, $(NH_4)_2PtCl_6$, prevented, as this would increase the apparent weight of the potassium platino-chloride. Likewise it must be kept free from alcohol vapour, in order to avoid a partial reduction to metallic platinum.

* The name Jaborandine having been thus appropriated, it will be necessary, should any crystalline principle be obtained from Pernambuco Jaborandi, to choose some other name for it, such as Pilocarpine.

† Abstract of a paper in the *Archiv der Pharmacie* [3], vol. ii, p. 407.

In any other analysis the use of a large excess of the reagent is avoided, here, however, the platinic chloride must be added in excess. Besides the potassium chloride, all the accompanying salts must be converted into platinum compounds. It is therefore necessary, in fact, to regulate the amount of platinic chloride in the solution by experiment, without confining it within too narrow limits. A potassium chloride rich in magnesium or sodium chloride will naturally require more than one poorer therein, the atomic weights of magnesium and sodium being considerably smaller than that of potassium.

There are certain signs by which it is known whether the platinic chloride is in excess or not. Firstly, in the latter case after evaporation the mass appears of a clear yellow colour, with whitish points on the edges; but when there is an excess of the reagent the fluid remains of a deep yellow colour during evaporation, and the residue is of the same colour. Secondly, sometimes the first alcoholic liquor is not orange coloured, but almost or nearly colourless, and in the capsule, besides the yellow, specifically heavy, crystalline, potassium platino-chloride precipitate, there are noticed light, white flocculent particles, which subside slowly, and are the first to go into the filter. It is particularly to the incompletely precipitated magnesium salt that this appearance is due. Notwithstanding that magnesium chloride is itself soluble in spirit, it is in this case very difficult to wash away. After the addition of the reagent it is evaporated at a temperature of 100° C. An evaporation to dryness is also recommended in order to drive off a small quantity of free acid which the platinic chloride might contain, as the presence of hydrochloric acid would favour the solubility of the potassium platino-chloride in the spirit. There is no need to fear the formation of platinous chloride, since this only commences at a temperature of 200° C. or higher. That salt is difficultly soluble both in spirit and in cold water. The alcohol should be as strong as possible, but neither absolute alcohol nor ether are positively required.

The moistening of the residue with a few drops of water and the rapid cooling of the capsule have for their object to restore the water of crystallization to the sodium platino-chloride ($Na_2PtCl_6 + 6H_2O$) present, which renders it more soluble. The mass does not become pasty upon the addition of water; it only changes colour and assumes a granular appearance. The dried dark yellow, almost brown contents of the capsule become again of a fine yellow colour upon the absorption of water. The precipitate is triturated with strong alcohol in order to separate the soluble compounds, which consist of the double platinum salts of sodium, magnesium, calcium, and barium, respectively. From this it will be seen that the previous removal of bodies compounded of the latter three elements is unnecessary. Fresenius directs the previous removal of the alkaline earths by means of oxalic acid or ammonium carbonate. This operation may therefore be omitted. During the filtration of the washings a suction apparatus is used to hasten the process, for which, without being absolutely necessary, Swedish filter paper should be used. The author employs simply thick blotting paper, selecting the best sheets for the purpose. A filter of this material, notwithstanding its absorptive power does not let the precipitate pass through. It must once more be pointed out that the platino-chloride of potassium must be washed to the last in the capsule by strongly triturating it with alcohol by means of a glass rod. Numerous experiments have shown that it is impossible to obtain a complete washing if all the original contents of the capsule are thrown at once upon the filter. Again it is especially the magnesium salt which is difficult to separate. After the last of the filtrate has drained off, and been tested for chlorine, the filter is taken from the funnel and the spirit absorbed by the paper is removed as much as possible. A neglect of this rule may cause the reduction of a portion of the platinum salt through the evaporation of the spirit. The filter is then folded together so that none of the powder can be lost by falling out, and it is placed in the drying closet, where it is laid upon a thin layer of blotting paper. The paper acts as a slow conductor of the heat, rendering it uniform on all sides, and besides takes up the last trace of the spirit. When the drying apparatus has been raised to a temperature of 120° C., it is sufficient to allow the filter to dry during half-an-hour at from 120° to 130° C. A lower temperature would require more time for a perfect drying; a higher heat would injure the filter and possibly lead to a reduction of the platinic chloride to platinous chloride. After the lapse of the proper time the filter is removed, placed between two watch-glasses, and immediately weighed; the weight of the filter, as above stated, is previously taken.

At this stage there are yet some indications which show whether the operation has been carefully and correctly performed. For instance, if the point of the filter is coloured yellow on the outside, or coated with yellow powder, it is a proof that the potassium platino-chloride has not been sufficiently washed, and the use of suitable reagents will show the presence of magnesia. A browning of the filter at a point below the above-mentioned shows that platinic chloride still remains in excess. The double salt forms a powder of a pure citron yellow colour, and must be free from any whitish appearance which would indicate insufficiency of platinic chloride, and consequently some yet undecomposed salt. In certain cases also it might be in the state of sulphate; for instance, if the sulphuric acid were not entirely removed in consequence of which the corresponding compounds are not dissolved by the alcohol. The entire operation does not require more than an hour and a half.

In all chemical operations it is of great importance to secure the purity of the reagents to be used; in this operation it is especially so. The author therefore proceeds to describe the manner in which the platinic chloride is usually prepared for use in the neighbourhood of Stassfurt from the platinum precipitates and washings of former operations. The process is divided into three parts: (1) the reduction; (2) the purification; (3) the solution of the platinum, to which is added a testing for purity.

(1) *Reduction of the Platinum Compounds.*—The reduction is effected by the action of sodium promoted by the presence of alcohol. The method was shortly described in the "Zeitschrift für analytische Chemie von Fresenius," and has been followed for several years. Formerly the platinum was usually reduced by hydrogen. It is now generally accomplished as follows:—The collected precipitates and the alcoholic washings are mixed together in a porcelain capsule, and the filters used are boiled with water so as to thoroughly exhaust them. The solution is afterwards added to the contents of the capsule. The whole is then warmed and carbonate of soda, free from sulphate, is added until there is a strong alkaline reaction. Probably fused caustic soda might be used for this purpose, as it is soluble in alcohol. If, however, a small quantity of water be added, such as would be required for the boiling of the filters, there would be no reason why the cheaper sodium carbonate should not be used. Care is taken, by frequent stirring with a glass rod, to raise the solution to the boiling point as quickly as possible in order to avoid unnecessary evaporation of the spirit. When this point is attained the platinum is almost suddenly precipitated in a pulverulent form from the solution. The sodium of the carbonate combines with chlorine from the platinum, sodium chloride together with potassium chloride go into solution, carbonic acid is evolved, the oxidized platinum is deoxidized through the action of the spirit, and the oxygen is taken up to form aldehyd, acetic acid, and oxidation products with the higher hydrocarbons.

(2) *Purification of the Platinum Sponge.*—The mixture is boiled a short time longer, and then left to subisde

thoroughly, which requires at least from four to six hours. The clear alcoholic liquor is then drawn off by means of a siphon, and filtered through ordinary filtering paper. Meanwhile water is poured over the powder, in which it is again boiled, in order to remove all the remaining adhering salts,—sodium chloride and carbonate, and potassium, magnesium, calcium and barium chlorides, together with any alcohol yet remaining. The platinum is again allowed to subside, for which less time is requisite now than before; the purer the platinum powder is the more quickly and completely it sinks to the bottom. If care be taken always to decant the liquors off clear they filter rapidly and the very small quantity of pulverulent metal retained by the filter does not retard the filtration. The third boiling is in water, to which a third part of hydrochloric acid has been added; this dissolves any carbonate that may have been formed which is not soluble in water.

The fourth boiling is with undiluted hydrochloric acid, which removes the last contaminations with difficultly soluble salts. In the fifth and sixth similar treatment only distilled water is used. After filtration of the last liquid the platinum powder is transferred to the filter by means of a wash-bottle, and washed with hot distilled water until the filtrate, when evaporated, leaves no fixed residue, and gives no reaction of chlorine. It is not advisable to dry the precipitate by heat. Even at a relatively low temperature, in consequence of the extraordinary capability of platinum black to produce oxidation, the filter begins to glow, and the powder itself is scattered about the drying closet.

(3) *Solution of the Platinum Powder.*—The acids for forming the solvent,—which is an aqua regia, consisting of five parts by weight of hydrochloric acid and one part of nitric acid,—are first weighed out. The former is taken up in a syringe, and used to remove the platinum powder from the filter into a roomy flask. The vessel is then placed in a water-bath, which is brought to gentle ebullition. Ten drops of nitric acid are now added, a drop at a time, mixed by gentle agitation, and the consequent reaction allowed to take place, in which the nitric acid is decomposed with evolution of brownish yellow vaporous compounds, $NOCl_3$ and $NOCl$. In consequence of the finely divided state of the platinum the action of the acid is immediate. A further small quantity of nitric acid is then added; if a large quantity be added at once it frequently happens that, through the violent evolution of vapour, half the mixture is driven out of the flask and lost. For such a contingency it is as well to have a capsule ready in which to collect the sudden overflow from the flask. The solution is completed in an hour. It is then allowed to cool and filtered through Swedish filtering paper, which has been previously washed with water acidulated with hydrochloric acid, in order to remove any trace of iron it may contain. The sandy residue which remains behind upon the filter consists of silicates taken up from the glass vessel. When dried it takes a chocolate-brown colour. The filtrate is evaporated in a well-glazed porcelain basin upon a water-bath, until a portion removed by a glass rod commences to solidify. A small quantity of hydrochloric acid is then added, again evaporating and repeating this with fresh hydrochloric acid until no further trace of nitric acid can be detected. In order to ascertain this, there is another special indication besides the colour and characteristic smell of the vapour. Upon the addition of hydrochloric acid to the concentrated solution, any nitric acid present is decomposed, which becomes perceptible by the effervescence of the solution. The nitric acid must be removed thoroughly, or it will form nitrogen compounds which will contaminate the reagent. This is shown when during the analysis of potassium chloride, after the addition of the platinic chloride and evaporation to dryness, there are formed in the capsule coal-black rings which become yellow upon the addition of water. In such a case the platinic chloride must again be concentrated and the nitric acid removed by hydrochloric acid. If an aqua regia be used, constituted in the proportion of 1 to 5, and the addition of nitric acid is stopped when a reaction is no longer produced, there will be no reason to fear the presence of nitric acid. After the last evaporation there should be no smell of chlorine or of hydrochloric acid perceptible. A crystalline film forms upon the surface of the solution, which is now left to cool, when the platinic chloride solidifies to a red-brown crystalline cake. This is dissolved in two parts of water, filtered through a filter previously treated as before mentioned, and the filter is afterwards washed with a small quantity of water. There remains only an insoluble residue.

Before using the reagent, its purity has to be tested. It should be of a red-yellow colour and as free as possible from an excess of hydrochloric acid; a dark red colour and opacity indicate the presence of platinous chloride, which may have had its origin in the evaporation of the platinum solution over a naked fire. As a further test the platinic chloride is tried with a pure potassium chloride the composition of which is known. Finally a weighed portion of the platinic chloride to be examined is evaporated to dryness, raised to a red heat and again weighed. The residue is examined to see whether it consists solely of platinum, and from this the quantity of platinic chloride is calculated.

The author states that the operation of preparing and testing platinic chloride in the above manner takes from two to three days.

THE BOTANICAL SOURCE OF MEDICINAL RHUBARB.*

Regel's *Gartenflora* for January contains, among other things, not the promised revision of species of *Rheum*, but a figure and description of, and some historical notes on, *Rheum palmatum var. Tanguticum*, by Maximowicz. Although he does not dispute the fact that *Rheum officinale* of Baillon, figured in the December number of the *Botanical Magazine* of last year, yields a commercial Rhubarb, he contends that the drug known in England as Turkey Rhubarb, which came to us through Siberia by way of Kiachta, was the produce of the plant he describes. We say came, because the trade from that source has been destroyed, not, as Maximowicz says, in consequence of the attempt of some of the tribes to overthrow Chinese rule, but, as related in Flückiger and Hanbury's 'Pharmacographia' in consequence of the very strict supervision exercised by the Russian Government. In the work just named a very full history of medicinal Rhubarb is given. Maximowicz's plant was collected by Przewalski, in 1872-3, in the vicinity of Lake Koko Nor, North-West China. It is, or was, extensively cultivated in that district, and the wild plant was also collected. An account is given of the method of its cultivation and preparation, but this part adds little to our knowledge of the requirements and conditions necessary for the profitable cultivation of Rhubarb. The plant figured agrees in all respects with a specimen in the Kew Herbarium labelled "Rheum palmatum, from Pallas," and also with another from Dr. Lindley; and there seems little doubt that the account given of its previous introduction about 125 years back is correct. The Russian officials stationed on the frontier were instructed to obtain seeds or plants of the genuine Rhubarb, if possible; and in 1740 they succeeded in obtaining a quantity of seed, though they had to pay a high price for it. But the "heathen Chinee" was too crafty for them, the plants raised from this precious seed proving to be nothing more than the well-known Siberian *R. undulatum*. However, 1750 the true plant was procured, and from Russia it spread over various parts of Europe, including Britain, so after all we have, according to Maximowicz, been seeking for a plant we already possessed. He goes on: "Let it be admitted that we now possess two species which furnish a superior quality of Rhubarb, still *R. palmatum* has the advantage of being the genuine plant that produced the drug whose repu-

* From the *Gardeners' Chronicle*, March 27.

tation dates from the time of the Arabian and Greek physicians." Speaking of the cultivation in Europe of Rhubarb for medicinal purposes, Maximowicz says that *R. palmatum* has proved rather unprofitable on account of the principal root decaying, and thus leaving only the less valuable lateral ones; and he adds that to a certain extent this has been the case with other species. So far as this country is concerned, we do not think these remarks are applicable. There is certainly a difference in the hardiness of the species. R. officinale was rather severely injured by frost at Kew last spring. We know nothing respecting the constitution of R. palmatum, but R. Rhaponticum, undulatum, and others are hardier than R. officinale.

THE ACTIVE PRINCIPLES OF THE OFFICIAL VERATRUMS.*

A Chemico-Physiological Study.

BY CHARLES L. MITCHELL,

Part II.—Chemical.

(*Continued from page* 770.)

VERATRUM VIRIDE.

Exp. No. 1. Thirty-two ounces of the powdered root were exhausted with alcohol 85 per cent., the first 16 fluid ounces saved, and the next 5 pints evaporated to 16 fluid ounces, and mixed with the first tincture. This fluid extract was now acidulated with 2 fluid ounces of acetic acid, poured into half a gallon of water, stirring constantly, and allowed to stand twenty-four hours. The precipitated resin was separated by filtration, and the filtrate evaporated to 1 pint, a little alcohol added to retain the colouring matter, and the whole precipitated by carbonate of soda in slight excess. On examining the filtrate from this I noticed at once that it seemed to possess considerable activity. It had the bitterish taste of the root, and left a numbing, tingling sensation in the fauces, which lasted for some time. It was, therefore, set aside for future examination. Continuing the process as described by Mr. Bullock, I soon found that I had scarcely any alkaloid left, it seeming to be quite soluble in an excess of the precipitating liquid. The substance I obtained weighed about 3 grains, was soluble in ether, and corresponded to the chemical and physiological reactions of veratroidia. The resin was next treated, in order, if possible, to extract the viridia from it, as according to Mr. Bullock's statements it existed there in considerable quantity, but the alkaloid obtained from it was pronounced by Dr. Wood to be also veratroidia. At a subsequent date, the alkaline residue which had been set aside at the beginning of the process was examined. It was acidulated with acetic acid, concentrated by evaporation, saturated with milk of lime, and the precipitate drained, dried, and exhausted with alcohol. The alcoholic solution gave on evaporation a resinous mass, which showed the colour reaction of veratroidia with sulphuric acid. On purification it yielded 10 grains of an alkaloid, one-third grain of which, when given to a cat, produced death within an hour, attended with all the symptoms of veratroidia poisoning. Jervia was also obtained as a by-product in this experiment, as a granular, white powder.

Exp. No. 2. Ten pounds of veratrum viride were exhausted with a menstruum of 3 parts alcohol and 1 part water, acidulated with muriatic acid, in the proportion of 1 fluid ounce of acid to every pound of root. This menstruum was adopted in order, if possible, to get rid of some of the resin, which had proved to be a source of great annoyance in the first experiment. The first 5 pints of tincture were saved, and the next 10 gallons of tincture evaporated to 5 pints, and mixed with that saved. This concentrated tincture was precipitated in 10 gallons of water, the resin separated by filtration, and the filtrate concentrated to 10 pints. Several different portions of 1 pint each were now tried with various precipitants, with the following results, the precipitate in each case being exhausted with alcohol, and the alcoholic solution evaporated to dryness:—

				Grains in 1 pint.
Carbonate of Soda,	yielded	impure	alkaloids,	10
Carbonate of Potassa,	"	"	"	12
Ammonia,	"	"	"	8
Magnesia,	"	"	"	25
Lime,	"	"	"	24

The precipitate from lime was nearly as great as that from magnesia, so lime, being a much less expensive precipitant, was used throughout the remaining experiments. The remaining 5 pints of liquid were precipitated with lime, and the alkaloids extracted, but I could find no viridia. I found the last menstruum, namely, that of three-fourths alcohol, not so well adapted for extracting the root as that first used, for it took up quite as much resin and an additional quantity of colouring matter, so that I returned to the original menstruum of alcohol. In order to make the plan of the following experiment more clear, let me say here that the main difference between viridia and veratroidia, given by Mr. Bullock, is that viridia is insoluble in ether.

Exp. No. 3. Five pounds of powdered root were exhausted with 85 per cent. alcohol, and a fluid extract prepared as before. To this 5 fluid ounces of acetic acid were added, and the whole poured into 4 gallons of distilled water. After standing twenty-four hours the resin was separated, and the liquid evaporated to 2 pints. During the evaporation, more resin was deposited, which was mixed with that first obtained, the whole dissolved in 2 pints of alcohol, and set aside. (1) Milk of lime was now added in excess to the concentrated acid liquid, and the precipitate separated after standing some hours, washed slightly to free it from colouring matter, drained, and dried. This was powdered, mixed with a small quantity of pure animal charcoal, and exhausted with boiling alcohol. On evaporating the alcohol the alkaloids were left as a hard, dark-brown, resinous mass. This was digested with very dilute sulphuric acid, and set aside for several days. By this means the major portion of the resin and jervia were separated, as a granular, dirty-white powder. This powder was filtered off and also set aside (2), while to the acid filtrate a little alcohol was added, and then a very slight excess of a strong solution of caustic soda (℥iv to Oj). A whitish, flocculent precipitate was produced, which in a short time assumed a semi-crystalline appearance. It was washed slightly, dried and powdered, and then agitated with successive portions of pure ether, carefully freed from alcohol, until all the veratroidia seemed to be removed, and a drop of the ether evaporated on a glass slide gave only a faint colour of the reaction with SO_3. On dissolving the remaining insoluble portion of the powder (which was much darker) in dilute sulphuric acid, adding ether and then excess of soda, more veratroidia was dissolved.

The heavier liquid was washed repeatedly with portions of fresh ether, but on testing the washings with SO_3, they would still give a faint colour reaction, showing that all the veratroidia had not been removed. It was, therefore, thrown on a filter and the insoluble resinous portion separated (*A*). Thinking that viridia when freshly precipitated might be soluble in ether, the ethereal liquids were treated in the following manner, those from the dry powder being kept separate from the washings of the fresh precipitate. They were agitated with successive portions of very dilute sulphuric acid, the aqueous liquid separated, concentrated, and then mixed with excess of sol. soda. The precipitates when washed were white powders, violently sternutatory, and of a bitter tingling taste. That from the dry powder weighed 30 grains, that from the precipitate (moist), 10 grains. The two carefully compared acted the same both chemically and physiologically.

---

* Read before the American Pharmaceutical Association. Reprinted from the 'Transactions.'

The insoluble resinous portion separated from the heavy liquid (*A*), was dissolved in water acidulated with SO_3, allowed to stand in order to separate some resin, and then precipitated with soda, washed and dried. It weighed 26 grains, and was of a darker colour than the first alkaloid. On testing this physiologically, it was found to produce all the effects of veratroidia, and by dissolving, separating the resin, precipitating, and washing with ether, several times, I succeeded in removing all the veratroidia, and found the portion which was still insoluble to be a mixture of resin with some jervia sulphate. The washings from all these different precipitates had been carefully saved, and were lastly examined, in order to ascertain if the viridia were dissolved in them. They were evaporated to dryness, treated with hot alcohol until everything soluble had been removed, the alcoholic solution decolorized with animal charcoal, evaporated to dryness, digested with very dilute sulphuric acid, and set aside. On standing a slight precipitate of resin separated, which was filtered off, a little alcohol added, and then sol. soda in excess. The precipitate washed and dried weighed 13 grains. It was found to be soluble in ether. Thus far most certainly no viridia.

The resin was next examined. The alcoholic solution previously set aside was agitated repeatedly with petroleum benzin, until all fatty matter had been extracted and the benzin solution evaporated. It left a greenish, oily, inert liquid, having a strong odour, and weighing 240 grains. Five drops of this injected into a pigeon had no effect. The alcoholic solution of the resin, freed from oil, was now acidulated with 5 fluid ounces of acetic acid, and precipitated in 2 gallons of water. This treatment was repeated several times, the acid liquors concentrated and precipitated with lime, etc., as before, yielding 50 grains pure alkaloid. It proved to be quite soluble in ether. The insoluble resinous portion gave the same result as before, being only veratroidia with resin and some jervia. This alkaloid was compared with the first veratroidia and proved to be the same. It is worthy of remark here, that the quantity of jervia separated from the resin was largely in excess of that obtained from the concentrated alcoholic tincture of the root. I, therefore, found no viridia in the resin. The jervia precipitates were mixed together, boiled with a strong solution of carbonate of soda to decompose the jervia sulphate, and the precipitate separated, washed until free from alkali, and dissolved in acetic acid; precipitated by sol. soda, washed and dried. It weighed 69 grains. I discovered one curious fact in connection with this alkaloid I had not before noticed, and which, I think, is worthy of mention. All authors speak of its insolubility in sulphuric acid, but I have observed that when very impure, and intimately mixed with resin and veratroidia, it appears to partake for the time of their solubility, and becomes quite soluble in that acid. When once purified it loses this property. I could therefore find no principle possessing the same solubilities and chemical reactions which characterize Mr. Bullock's viridia. Thinking that perhaps I might have made some error, my investigations were twice repeated, but with the same result. An experiment was also tried of exhausting the root with diluted acetic acid, but my experience was that it did not do it thoroughly.

The alkaloid veratroidia thus extracted is a white powder, uncrystallizable, of a bitter taste, leaving a tingling sensation in the fauces, violently sternutatory, and extremely irritating. It fuses at 265°. It is soluble in alcohol, amylic alcohol, ether, chloroform, carbon bisulphide, and when precipitated very slightly in petroleum benzin. It forms soluble salts with the acids, most of which are uncrystallizable. The alkalies and their carbonates precipitate it from acid solutions in white, semi-crystalline flakes, which are slightly soluble in excess of the precipitant, especially when ammonia is used.

Jervia is a white powder, capable of crystallizing from an alcoholic solution, tasteless, not sternutatory, and of a slight alkaline reaction. It is insoluble in water. It is freely soluble in alcohol and chloroform. With acetic and phosphoric acids it forms very soluble salts; with sulphuric, hydrochloric, and nitric acids, it yields salts sparingly soluble in alcohol and water, and precipitated from the more soluble acetate and phosphate. When heated it melts to clear oil, at a little above 400° F. turns brown, and when the temperature is raised still higher, it burns with a smoky flame.

The resin when freed from alkaloids is dark-brown, tasteless, inert, soluble in alcohol and alkaline solutions, and very slightly soluble in diluted acids.

The yield of alkaloids from veratrum viride varies considerably in different lots of the root, as does also the amount of resin. I append the yield per pound of three different lots, as compared with the results of Mr. Bullock and Dr. Peugnet.

	Lct. 1.	Lot 2.	Lot. 3.	Bullock.	Peugnet
Veratroidia, grs.	18·3	24·5	28·6	4·6	4·3
Virida, ,,	..	..	..	14·3	..
Jervia, ,,	16	18·2	20·5	..	7·5
Resin, ,,	115	110	192	..	..
Oily matter, ,,	10	25	50	..	..

Lot No. 3 was a fine sample of veratrum viride, the others were ordinary specimens. The quantity of resin and alkaloids very probably varies with the time of gathering. I do not think the alkaloids can be profitably extracted.

The results of this investigation differ considerably from those of Mr. Bullock, but I think they are in the main correct. Most certainly there did not exist in any of the lots of veratrum viride which I examined (and they were all good, fair samples of the root, and ground directly under my personal supervision), any active principle which corresponds chemically to viridia. I have every time succeeded in finding both jervia and veratroidia, even in the preliminary experiments. The question immediately arises does there exist such a principle in verat. viride, besides the other two alkaloids? I say no, and as the physiological experiments will prove, jervia has all the physiological effects of viridia on the system. Mr. Bullock must therefore have confounded the two, as he makes no mention of jervia anywhere in his paper.

The most efficient preparations of this root are the officinal tincture, fluid extract, and extract. If its virtues are desired in a more concentrated form they may be obtained by the following formula, which gives a powder corresponding to the eclectic "veratrin."

Grd. Verat. Viride . .	1 lb. av.
Calc. Magnesia . . .	100 grs.
Alcohol	q. s. or 4 pints.

Exhaust the verat. viride with the alcohol, evaporate the tincture to syrupy consistence (about 2 fluid ounces), add the magnesia, mix well, and then gradually add 1 pint of water, stirring constantly. Separate the precipitate, drain, dry, and powder. Yield, 330 grains. This contains all the active principles of the root, and acts powerfully in doses of from ¼ to ½ grain.

The following is the result of a quantitative analysis of the root of veratrum viride:—

NaCl,	·490	Percentage of water lost by drying root four days, 8·45.
Na_2O,	1·370	
K_2O,	23·020	After drying as above, total percentage of ash in dried root, 4·63.
CaO,	17·730	
MgO,	6·065	(The determination of the total percentage of ash in the root being a very important point, great care was taken, and five parallel experiments made, with good results; the above stated percentage may, therefore, be regarded as nearly correct.)
SiO,	5·670	
FeO,	6·420	
P_2O_5,	9·380	
SO_3,	8·190	
CO_2,	11·200	
Sand,	11·920	
Carbon,	·149	
	101·604	

VERATRUM ALBUM.

The preceding experiments with veratrum viride, made many of the preliminary investigations unnecessary for the examination of veratrum album, so that the following process was at once followed out.

Ten pounds of powdered root were moistened with 1 gallon of alcohol 85 per cent., allowed to macerate twenty-four hours, and then percolated with q. s. alcohol to exhaust. The alcoholic tincture was evaporated to 5 pints, acidulated with 5 fluid ounces of acetic acid, and precipitated in 5 gallons, previously acidulated with 5 fluid ounces of acetic acid. The resin was separated, and the filtrate evaporated to 4 pints, the deposited resin being removed, mixed with that first separated, and the whole dissolved in 2 pints of alcohol, and set on one side. To the filtrate was added milk of lime in excess, the precipitate separated, washed, dried, powdered, mixed with a little animal charcoal, and digested repeatedly with boiling alcohol, until nothing more was taken up. The alcoholic tincture was evaporated to dryness, and the resinous mass left, digested with dilute sulphuric acid, and after everything was dissolved, concentrated to a small bulk and allowed to cool. A considerable quantity of jervia sulphate separated, which was filtered off, and set on one side for purification, while to the filtrate a little alcohol was added and then sol. soda in slight excess. The precipitate produced was separated, washed, and dried. It weighed 136 grains, and when treated with pure ether behaved in a similar manner to veratroidia, fully dissolving when freed from jervia and resin. The alkaloid extracted from the dry powder and that from the fresh precipitate were kept separate, in order to be physiologically tested, and marked respectively "Alkaloid A," and "Alkaloid B." The alcoholic solution of resin previously set aside was freed from oil and fatty matter, by frequent agitation with petroleum benzin, and after the addition of 10 fluid ounces of acetic acid, was precipitated in 2 gallons of distilled water. This treatment was repeated several times, until the resin seemed to be totally deprived of active matter. The acid liquors yielded 134 grains alkaloid, which was found when freed from resin to be wholly soluble in ether. It was the same as the alkaloid first obtained. The filtrates and washings from these different precipitations yielded 30 grains more of alkaloid.

The benzin washings gave when evaporated a yield of 3 ounces of oily matter, a much larger proportion than that existing in veratrum viride.

The jervia precipitates when purified yielded 84 grains of jervia. The resin weighed 2400 grains, and appeared like the resin of veratrum viride. It was tasteless, odourless, and as far as my experiments went, nearly inert.

About this time I received from Dr. Peugnet, with whom I had been carrying on quite a discussion, a few grains of the resinoid (as he termed it), which he had found so active, $\frac{1}{20}$ grain of it having killed a pigeon within an hour. It was dissolved in alcohol, acidulated strongly with acetic acid, and kept warm for some time; after which it was poured into 6 fluid ounces of water, the resin carefully separated, and the filtrate evaporated to a small bulk. The evaporation caused the separation of more resin, which was filtered out, and the clear solution precipitated with sol. soda. This precipitate when dried weighed nearly 2 grains, and proved to be an alkaloid identical in its reactions with the one I had previously obtained in my experiments. Several physiological experiments were made with a solution of this alkaloid, and a solution of the resin from which the alkaloid had been removed. The results proved conclusively, that the resin of verat. album is, like the resin of verat. viride, nearly inert. The error of Dr. Peugnet lay probably in the fact that his impure resin was treated in the solid form with the diluted acids, in which condition the alkaloids can be but partially removed, instead of dissolving the resin in alcohol, then acidulating, and finally precipitating in water.

(*To be continued.*)

MEDICAL SCALE FOR EMIGRANT SHIPS.

INSTRUCTIONS TO SUPERINTENDENTS OF MERCANTILE MARINE OFFICES.

The annexed Scale of Medicines and Medical Stores for Emigrant Ships has been issued and caused to be published by the Board of Trade, and is intended to supersede the Scales hitherto in force.

SCALE OF MEDICINES, MEDICAL STORES, AND INSTRUMENTS.

For every 100 Passengers, when the length of the passage, computed according to the Passengers Act, is 100 days and upwards. Half the quantity of the medicines indicated, and the same kind and quantity of Medical Stores and Instruments to be taken, when the passage is less than 100 days.

Directions for Druggists.	———	Lbs.	Oz.	Dr.

The Pharmaceutical Journal.

SATURDAY, APRIL 3, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACY IN IRELAND.

OUR columns, during the last few weeks, have borne testimony to the existence of a somewhat acute state of agitation on the other side of St. George's Channel in regard to the subject of pharmaceutical legislation. In performance of our duty as journalists, we have from time to time recorded such information as was obtainable in reference to this matter, but under the peculiar circumstances of the case we have deemed it advisable to confine ourselves, as far as possible, to the mere statement of what was taking place.

Naturally, correspondents have come forward to make known their particular views, and we have freely given them opportunity of doing so, although some of them have taken exception to what we have said on the subject and have assumed that we were labouring under a delusion. Whether this be the case or not we will not now stay to inquire, since we are sensible of a deficient acquaintance with the actual facts. At the same time, we must so far defend ourselves as to state that we have, in any remarks on the subject of Irish Pharmacy, impartially received the statements made by the various parties concerned, and, conscious of the deficiency we have already admitted, confined ourselves to general considerations upon those grounds.

Mr. HARTT was the first to object to the course we have taken, and, in doing so, he asserts that the classes we spoke of, viz., chemists and druggists, as well as pharmacists, are "non-existent in Ireland;" in short, that there are only apothecaries who are really qualified medical practitioners, and druggists keeping general stores, but destitute of that knowledge which would qualify them for dispensing prescriptions.

Though we are unable to express any decided opinion as to the general qualification of the druggists who are debarred by the Apothecaries Act from dispensing medicine, we cannot, in common fairness, ignore the fact that there is an association of persons calling themselves chemists and druggists and contending that on the ground of their ability to do the work of the pharmacist they should be freed from disabilities under which they have hitherto laboured. This association also seeks to establish a system of educational training and a means of testing the competence of persons desirous of obtaining the qualification to dispense medicines. In the abstract we heartily sympathize with this endeavour, and we cannot disregard the fact that it receives the countenance of distinguished members of the medical profession in Ireland. Moreover, there is the fact that this association has among its members several whose names are honourably known as pharmacists of unquestionable attainments. In short, we think that, if delusion prevail at all on this subject, it is our correspondent who labours under it in supposing that we should support the attempt to give a dispensing qualification to any individual who was not able demonstrate his claim to it.

Our second correspondent—"Common Sense"—raises objections of a different nature. "Where," he says, "are the funds to come from?" That is, however, a matter of detail to be dealt with by these who are endeavouring to establish an amendment of the existing state of things, and we must assume they are prepared to face this question.

The letters of some subsequent correspondents, including one from an "Irish Licentiate Apothecary," all seem to betray a fear that the passing of an Irish Pharmacy Act would open the door for incompetent persons to dispense medicines and assume the status of the pharmacist; but we cannot share this apprehension. None of the Bills that have been proposed justify it in any degree, for they all stipulate that qualification is to be granted only on the basis of examination. Indeed, the condition of matters in Ireland is such that there is much less difficulty to be overcome in framing a Pharmacy Act for that country than there was in Great Britain. There is no habitual right to dispense medicines except that pertaining to the licentiate apothecary. Those who, while outside this privileged body, claim to share an equal privilege with them must certainly submit to the demand that in the interests of the public they shall be subjected to the same tests of practical skill and knowledge that are required of the apothecary in regard to pharmacy. We are not aware that there is any dissent from this proposition on the part of the Chemists and Druggists' Association, though an objection is reasonably urged by that body against the present more extended examination of the Apothecaries' Hall, which presupposes an educational curriculum sufficient to qualify for medical practice as well as pharmaceutical practice.

The object to be attained in regulating the practice of pharmacy in Ireland seems indeed a very simple one: it is that of merging in one, the pharmaceutical qualification of the apothecary and the pharmaceutical qualification of the druggist. This plan is not only obviously desirable when regarded from an abstract point of view, but it has also in a very essential particular the support of practical experience, for it is a fact that a large number of the apothecaries of Ireland confine their attention solely to the practice of pharmacy, although they have had to undergo a medical and surgical training as well as the pharmaceutical education. On the other hand, the qualification of the Apothecaries' Hall for the practice of medicine seems to be generally regarded as insufficient for that purpose, since most of the apothecaries who practise medicine have some other medical qualification besides, on the strength of which they act as general practitioners.

But though on the ground of practice and in the abstract, the course to be taken is clear enough, and though the difficulties which beset the Pharmacy Act of 1868 do not exist in Ireland, there is still an obstacle to be overcome. A moribund corporation has to be eliminated, in order to make place for the more appropriate system; its vested rights are the object of admiration to some and of antipathy with others; hence personal feelings, which have already been manifest in our correspondence on the subject, will array on opposite sides many who have in reality the same object in view, and for a while the real merits of that object will be obscured by the contest as to the means by which it is to be attained.

We hope very shortly to be in a position to furnish further information as to the proposed reform of Irish Pharmacy by publishing the Draft Bill of the Chemists and Druggists' Association.

MEDICAL SCALE FOR EMIGRANT SHIPS.

The revised scale of medicines, medical stores, and instruments, which we have printed *in extenso* this week (p. 787), has just been issued by the Marine Department of the Board of Trade (who are now responsible for the official conduct of emigration business), and is intended to supersede the scales hitherto in force. There can be little doubt that, for several years, this revision has been very much needed. Two scales of medicines and medical stores have existed up to the present time; the one referring to vessels about to proceed on voyages of more than 100 days' duration, the other to "short voyage" ships. Both these lists were much behind the age, having been compiled about half a century ago. The medical advisers of the Board have, in the present instance, somewhat simplified matters by correcting the two lists, and arranging that, in the matter of medicines, half the quantities ordered shall be sufficient for "short voyage" ships. Many of the special "Directions for Druggists" given are precisely similar to those in the "Scale of Medicines for Merchant Ships" revised some six years ago. All pills are to be ready made, and a uniform five grains' standard is adopted. Double the quantity of astringent powder and quinine are to be provided for all ships proceeding to tropical ports, and a neutral solution of morphia is ordered for hypodermic injections. Desiccated soup is added to the list of stores, which contains, besides, several important additions in way of bandages, etc., including the simple triangular bandage so much used in the Franco-German war, and specially described and illustrated in the last edition of the authorized 'Ship Captains' Medical Guide.' And it is also to be noted that the list includes a set of instruments, which are not, as before, recommended, but must, as we suppose, be supplied either by the owner or the surgeon in charge of the emigrants.

All of our readers interested in this revised scale will at once perceive that its adoption will necessitate many changes in the form and arrangement of ships' medicine chests, cases, etc. It is to be observed that though only half the medicines indicated need be carried in "short voyage" ships, the full quantity of stores must be taken, except those marked with an asterisk. Of course, only one set of instruments is in any case required. We reserve critical comments until the revised scale is fairly floated; but may say that a vigorous effort has been made to simplify and, so to speak, codify the old lists as much as possible.

Many of our readers will be glad to learn, as we are to state, that Dr. J. Baker Edwards, of Montreal, formerly of the Royal Institution, Liverpool, has been appointed Consulting Chemist to the Inland Revenue Department of the Dominion of Canada. This appointment will include the duties of Food Analyst, under a recent Act for the prevention of the adulteration of food, drink, and drugs, and of Gas Analyst, under another Act in the same department. It is in contemplation to establish ultimately a laboratory for the department in the public buildings at Ottawa, but, for the present, the head-quarters will be in Montreal.

It is anticipated that some of the difficulties and inconsistencies experienced in Great Britain in carrying out the Adulteration Acts will be avoided by placing the entire executive in the hands of the Crown. In selecting Dr. Baker Edwards to this highly responsible office, another laurel is won for the pharmaceutical profession and for the pioneer band of early students at Bloomsbury Square. We heartily congratulate him on his appointment to this important post, and hope occasionally to hear of the results of his labours.

On Wednesday evening next, March 7th, the last Evening Meeting of the Pharmaceutical Society for the present session will be held. Professor Hofmann, of Berlin, has kindly promised to exhibit and briefly describe on that occasion the specimens used in illustration of his recent Faraday lecture on Liebig's Contributions to Chemical Science. The following papers also will be read,—"On the Identity of Chrysarobine or Araroba," by Mr. E. M. Holmes; "Notes on the Pharmacy of Atropine," by Mr. W. Willmott; and "Ergot and its Liquid Extract," by Mr. A. W. Gerrard.

At the recent Annual General Court of the Governors of the Royal Hospital for Diseases of the Chest, Dr. Horace Dobell, who has for sixteen years discharged the duties of Physician to the Hospital, was elected a Consulting Physician.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

At a meeting of the Bristol Pharmaceutical Association, held on Thursday, March 25, a paper was read by Dr. Spencer, of Clifton, on "The Relations of Modern Medicine to Modern Pharmacy." The paper will be published *in extenso* in an early number of this Journal.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The sixth scientific meeting of the session of this Society was held in Anderson's University, on Wednesday evening, February 17. Mr. W. Whyte, Vice-President, in the chair. Mr. Emmerson MacIver, F.C.S., delivered a lecture on "The Spectroscope," which was highly interesting and instructive. At the close the customary vote of thanks was awarded to Mr. MacIver. Several new members were enrolled, and donations announced.

On March 17, the seventh scientific meeting was held in the usual place. Mr. J. Currie, President, presided. There was a good attendance. Dr. Hugh Miller, delivered an address on "Some of the Laws of Health." The address was delivered in a popular style, being interspersed with humorous anecdotes illustrative of the different heads under which the speaker had divided his subject, and showing the difficulties which medical men experienced in getting even educated people to understand and act up to the simplest laws, such as a careful selection of food, having it well cooked, and partaken in moderate quantities and at regular intervals. Pure air, pure water, good dwellings, personal cleanliness, including frequent use of the bath, climate, soil, winds, and the seasons, and their effects upon health, were each referred to by the lecturer, together with a minute description of the human body, pointing out the necessity for its welfare, that those laws he had alluded to should be strictly adhered to. But so long as public works, especially chemical works, were permitted to send into our cities and towns their obnoxious vapours, so long as ill-ventilated houses were crowded together and built on badly drained soil, so long would typhoid, small-pox, and other contagious diseases continue in our midst.

Mr. William Dittmar, F.C.S., the new Professor of Chemistry in the Andersonian University, was afterwards introduced, and delivered a lecture on "Artificial Illumination." In the course of the lecture he described in a most interesting manner the nature of heat and light, the various theories which have been given out regarding them, and their respective properties and uses in the economy of nature, referring *seriatim* to the different heads, energy, conduction, expansion, convection, radiation, refrangibility, the spectrum, etc., each point being illustrated by a series of striking and beautiful experiments.

At the close the Chairman proposed a cordial vote of thanks both to Dr. Miller and Mr. Dittmar, for their very valuable and able lectures. He said Dr. Miller's paper had doubtless cost him a great deal of careful research and thoughtful study, and they would derive much benefit from the intelligent rehearsal he had given them of his observations and experiences. As regards Mr. Dittmar's lecture it was sufficient of itself for one night; the subject was a vast one, but Mr. Dittmar had done it justice. His statements had been made so clear and his experiments had been so successfully performed that all must have followed him with pleasure, and as teacher of chemistry to the association, they must be proud of their connection with him and the "Andersonian." The votes of thanks were unanimously and enthusiastically responded to. The consideration of the Food and Drugs Bill and other business were deferred till next meeting.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

The fifth meeting of the session was held February 16th, 1875, the President, Mr. Dillwyn Parrish, in the chair.

Mr. Walling exhibited a specimen of an impure carbolic acid, which had been recently offered as creasote, and spoke of the difficulty experienced in obtaining genuine wood-tar creasote.

Professor Remington remarked that the dealers in the United States were in the habit of supplying coal-tar creasote, unless wood-tar creasote were specified in the order.

Professor Maisch called attention to the variable composition of creasote as displayed in six specimens exhibited by him, all of which were free from carbolic acid, yet differed more or less in smell and reaction. He believed that the reactions and properties of creasote made in different countries and by different manufacturers would continue to vary, until creasote ceased to be a mixture of several products of the dry distillation of wood and its correct chemical composition had been ascertained. At present, he thought, that perhaps the most reliable test was its miscibility with collodion without coagulating it.

Mr. W. McIntyre said he had procured some of the oil of Ceylon cinnamon referred to at the previous meeting (see before, p. 690) and with it prepared some cinnamon water which he found to possess the sweet taste he had presumed was characteristic of cinnamon water prepared by distillation.

A paper was read by Dr. Miller entitled, "Notes on Pronunciation and Orthography," urging that more attention should be paid to the correct rendering of many words in common use. Two papers on Suppositories were also read, one by Mr. R. V. Mattison, advocating the making of these preparations in moulds, the other by Mr. Kemble, recommending the hand method.

Professor Remington read a letter enclosing the first thesis presented to the California College of Pharmacy, of which the following is an abstract:—

Volatile Oil of Oreodaphne Californica.
(*California Bay Laurel*).

BY J. P. HEANEY.

The *Oreodaphne Californica*, more familiarly known by the name of "California Bay Laurel," is an evergreen tree indigenous to California and the Pacific slope. It acquires considerable size and age, and grows abundantly throughout the State, particularly in the vicinity of ravines and moist, shady localities; it flowers in June. The wood is much valued for ornamental cabinet-work, on account of its grain, which, when polished, presents a fine appearance. The tree is never attacked by insects, owing, as it is supposed, to the volatile oil it contains. Some of the native Californians have peculiar ideas concerning this tree. It is believed by them to aggravate asthmatic complaints, and that sleeping in the vicinity of the tree will even produce asthma. That it is not without some action on the system has been proved by the inhalation of its odour often producing dizziness and violent headache.

All parts of the tree contain volatile oil, but the leaves yield the most, about four per cent. being obtained by distillation. The oil is of a straw-colour, limpid, and has a pungent aromatic odour, resembling a mixture of nutmegs and cardamoms. Its taste is warm and camphorous. It burns with a bright, smoky flame, leaving a carbonaceous residue. Its specific gravity is ·936. It is soluble in about 1000 parts water, and mixes in all proportions with alcohol and ether. The oil, when inhaled, produces dizziness and headache, and is therefore deemed to have a marked action on the nervous system, a property which has been applied to its medicinal use. Dr. Silver recommends the smelling of the oil in nasal catarrh and nervous headache, and speaks of successful results.

Examination of the Oil.—The method of investigation adopted was that recommended by Frederick Rochleder in his work 'On the Proximate Analysis of Plants and Vegetable Substances.'

The oil being neutral to test-paper, it was tested for aldehydes with a concentrated solution of bisulphite of soda, with which no combination could be effected, even after the application of heat.

A fragment of sodium introduced into the oil, previously dried by contact with chloride of calcium, produced no effect until a gentle heat was applied, when the metal dissolved slowly, with the disengagement of numerous gas bubbles, the oil assuming a reddish-brown colour. It now possessed an alkaline reaction, and the peculiar pungent odour was not distinguished.

To prove whether the oxygenated body present was a compound ether, the oil was treated with ammonia without producing an amide, and no acid was separated by prolonged treatment with baryta.

By slow distillation, with an excess of coarsely-powdered soda lime, a colourless, limpid distillate was obtained, of an aromatic odour, resembling oil of nutmegs. It gave a slight reaction with sodium, but, after redistillation over soda lime, and again over sodium, it was obtained neutral. It possessed all the characteristics of a hydrocarbon, free from oxygenated bodies.

Two fluid ounces of the crude oil, freed from moisture by contact with chloride of calcium, were introduced into a small glass retort having a thermometer inserted in its tubulure. It was slowly heated up to 190° C., and about four drachms of a colourless oil were obtained. The thermometer rose with the successive portions obtained as follows: three fluidrachms were obtained from 190° to 202° C., three fluidrachms between 202° and 205° C., three fluidrachms between 205° to 220° C., two fluidrachms between 220° to 230° C., and one fluidrachm between 230° to 245° C. The remaining oil in the retort possessed a very dark colour and a thick consistency. Its odour was also less decided, the taste greatly less pungent, and it ignited less readily than the crude oil, burning with a brilliant but sooty flame; evaporated from bibulous paper, the vapour first given off was very pungent, while the latter portion was almost devoid of this odour. The boiling-points of the different fractions were next ascertained by heating them in a test-tube, with a thermometer inserted. The first fraction began to boil at 175° C., the second at 180° C., the third at 185° C., the fourth at 196° C., the fifth at 214° C., and the sixth at 220° C. The existence of two distinct oils in the crude oil is therefore quite probable; but, by cooling the oil with ice for twenty-four hours, no separation could be effected.

Two fluidounces of the crude oil were carefully and very slowly distilled from a small glass retort, having a thermometer inserted, at a temperature not exceeding 180° C.; about one ounce of an almost colourless distillate was obtained, possessing the penetrating, pungent odour of the crude oil to a high degree. On gradually raising the temperature to about 210° C., but not to exceed 220° C., a distillate of about six fluidrachms was obtained, which was of a light straw-colour, less limpid, and had an acrid, pungent odour, differing greatly from that of the crude oil or the previous distillate. Its taste was sharp and camphorous. The residue in the retort had turned quite black, and of the consistency of syrup.

The fraction obtained at 180° C. was treated with sodium, with which no reaction was observed until the application of a gentle heat. The second fraction, obtained at 220° C., gave, with sodium, the characteristic reaction of an oxygenated oil.

To avoid the oxidizing action of the atmosphere and the decomposing influence of direct heat, two fluidounces of the crude oil were again distilled from a glycerin bath, and carbonic acid gas, dried by passing through sulphuric acid, conducted into the retort. The distillate obtained at 175° C. was colourless, limpid, and had lost nearly all of its pungency, having a pleasant aromatic odour, resembling oil of nutmegs; it gave less reaction with sodium than in the previous experiment. The second distillate, at 220° C., was of a much lighter colour and a more agreeable odour, but retaining its previous pungency. All the oil which came over under, but not to exceed 175° C., was reserved for the separation of the hydrocarbon, while that between 175° and 220° C. was used for the separation of the oxygenated oil. The fractions having the lower boiling-point were rectified in an atmosphere of hydrogen over caustic potassa and over soda lime, both processes yielding identical results—the distillates being obtained absolutely free from oxygen when rectified over sodium. The portion with the higher boiling-point distilled completely between 180° and 210° C., and was collected in three fractions, each of which commenced to boil between 205° and 210° C. when heated separately.

Hydrocarbon.—The pure hydrocarbon is a colourless, limpid liquid, possessing an agreeable aromatic odour, bearing some resemblance to a mixture of camphor and oil of nutmegs. Its taste is like that of cardamoms. Its specific gravity is ·894 at 15·5° C., and its boiling-point is 175° C. It is very volatile and highly inflammable, burning with a brilliant, slightly smoky flame. It is nearly insoluble in water; soluble in about five parts by volume of 95 per cent. alcohol. It dissolves iodine slowly, acquiring a deep red colour. Nitric acid, added to it and heated, causes a violent reaction, with the disengagement of nitrous acid fumes, the production of a yellow colour, and the disappearance of the odour of the hydrocarbon. Nitrous acid occasioned a rapid and violent reaction, with the production of heat. When heated with sulphuric acid, a thick, reddish mixture was obtained, becoming black, and disengaging sulphurous acid gas.

Oreodaphnol.—This is the oxygenated portion of the crude oil, and was obtained between 175° and 220° C. It is an oily liquid, of a light straw colour, and of a pungent and penetrating odour. Its taste is hot and camphorous; its specific gravity ·960. It is very inflammable, burning with a bright flame, giving off pungent vapours, and leaving a carbonaceous residue. Its boiling-point is 210° C. It dissolves iodine, with the generation of a slight heat, and the production of a reddish-brown solution. When treated with sulphuric acid a reaction was observed, accompanied with increase of temperature and the disengagement of sulphurous acid. Nitric acid exerted no action in the cold, but when heated, a violent reaction resulted, and nitrous acid fumes were given off. Treated with sodium, a reaction was observed.

Oreodaphnene.—Oreodaphnene is generated when oreodaphnol is distilled with glacial phosphoric acid, in an atmosphere of dry hydrogen gas. Thus obtained, it exhibits a light straw colour, and possesses a pungent terebinthinate odour. Its taste is hot and camphorous, followed by a feeling of acridity, which remains in the mouth for a length of time. It is specifically lighter than oreodaphnol, its specific gravity being ·934, and it has a boiling-point of 204° C. It burns with a white flame, giving off very pungent vapours. It is soluble in about 4 parts of 95 per cent. alcohol. Iodine dissolves in it, producing a reddish-brown solution. Nitric acid changes its colour to a deep red, with the elevation of temperature and disengagement of nitrous acid fumes. Nitrous acid gave a violent and rapid reaction, and sulphuric acid a reddish-brown solution. Treated with sodium, no reaction was observed. It is therefore the hydrocarbon of oreodaphnol, generated by the abstraction of water.

The hydrocarbon and the oreodaphnol are contained in the crude oil in about the proportion of one part of the former to two parts of the latter. It is upon the oreodaphnol that the peculiar pungency of the crude oil depends.

This was followed by the reading of a paper entitled—

DEER TONGUE (*Liatris odoratissima*) IN PERFUMERY.

BY DR. MILLER.

Deer tongue, or Southern vanilla (*Liatris odoratissima*, Willd.), seems destined to become a commercial staple of some importance, chiefly, so far, on account of its large consumption as a flavour for tobacco. It is stated to be also used to some extent in the South for the purpose of preserving clothing, woollen fabrics, etc., from the attacks of moths. To the best of my knowledge, these are the only applications which have yet been found for these highly odoriferous leaves. The chemistry of deer tongue has been treated of very ably and exhaustively by Professor Procter, proving it to contain a large percentage of coumarin.

As it has been a matter of surprise to me that no perfumer has, as yet, availed himself of the Southern vanilla, I have contrived the following formulæ, which, in my opinion, furnish quite satisfactory results.

Tincture of Deer Tongue.—Percolate two ounces of ground deer tongue leaves with Cologne spirits until one pint of tincture is obtained. This is of a handsome light green colour, so that it can be readily employed as an addition to various extracts, Colognes or toilet waters. In its pure state, it may be used as a substitute for the essence of May wine (a tincture of the fresh leaves of *Asperula odorata*), which is used extensively in Germany as a pleasant addition to wine, converting it into the so-called May drink (*Maitrank*).

Extract of New-mown Hay.

Tincture of Deer Tongue	8 ounces.
Extract of Rose from Pomade	4 ,,
,, Orange Flower from Pomade	4 ,,
Oil of Rose, Virgin Serail	16 drops.

New-mown Hay Sachet Powders.

Ground Deer Tongue Leaves	2 ounces.
,, Florentine Orris Root	
,, Damascene Rose Petals	
,, Orange Flowers . . . . . of each	1 ounce.

Mix thoroughly and sift.

Sachet Bouquet.

Ground Deer Tongue Leaves	2 ounces.
,, White Santal Wood	½ ounce.
,, Florentine Orris Root	1 ,,
,, Ambretta Seeds	½ ,,
,, Benzoin	¼ ,,
,, Damascene Rose Leaves	1 ,,

Mix, and sift to remove coarse particles.

'Gray's Botany' states that the leaves, when bruised, exhale the odour of vanilla, but I cannot confirm the assertion. I have tried various combinations of vanilla and deer tongue, with a view to its use as a flavour, but each of them was unsatisfactory. The odour and taste of coumarin appear to be so much stronger and so much more persistent than that of vanilla, that it is only spoiling good vanilla to add tonka or deer tongue to it.

Deer tongue is specially adapted to imitating the odour of new-mown hay, as the perfume of this also resides in the coumarin contained in *Anthoxanthum odoratum*, Lin., or sweet-scented vernal grass.

Professor Maisch read a paper on the "Constituents and Properties of the Genus Potentilla."

SOCIETY OF ARTS.

ALCOHOL, ITS ACTION AND ITS USES.*

BY BENJAMIN W. RICHARDSON, M.D., F.R.S., etc.

LECTURE IV.

(*Concluded from page 775.*)

DISPOSAL OF ALCOHOL IN THE ORGANISM.

We are brought now to one of the most important parts of our study. We see that, under favouring conditions, alcohol will oxidize in the presence of the air. We see that it will oxidize in two ways—actively with the production of much heat and with the formation of carbonic acid and water; passively with the production of aldehyde and acetic acid.

In the human body do any similar changes take place? Throughout the whole of this vast sheet of the minute circulation there is ever in progress, during life, a process of slow oxidation of carbon and hydrogen, by which heat is produced, and carbonic acid and water are produced. The heat is proved by the animal warmth which is ever present in our bodies while we live; the carbonic acid and water, as products, are proved by their continued presence in the secretions from the lungs, skin, and other organs.

Alcohol, we have seen, is carried by the blood into this minute circulation. Is it possible it can pass through that ordeal and undergo no chemical change? If it does undergo any changes, what are their nature? These questions have occupied the attention of many gifted minds; but they are not yet solved. Let me endeavour to put the position in which they stand plainly before you.

The earlier physiologists of this century came naturally enough to the conclusion that the alcohol taken into the body is consumed there with the evolution of heat. A certain development of heat in the superficies of the body, and a certain sensation of glow which follows upon the imbibition of spirit lent countenance to this suspicion. But in course of time, independently of any knowledge of the effect produced by alcohol in the minute circulation of the blood it began to be doubted whether alcohol was disposed of in the organism by its combustion. Some observers had noticed, in conducting the examination of the body after death from excess of alcohol, that the odour of the substance was present in the tissues, especially in the nervous tissue, and it was doubted whether the alcohol might not under some circumstances remain in the organism without undergoing any change at all. In 1860 three eminent Frenchmen—Lallemand and Perrin, assisted by Duroy, published a prize essay on alcohol, in which this view was maintained, or as the authors would probably say, was originated; for in truth they were the first to state the view on direct scientific evidence. From the result of many experiments, they came to the conclusion that alcohol taken into the living body accumulates in the tissues, especially in the liver and in the brain, and that it is eliminated by the fluid secretions, notably by the renal secretion, as alcohol. They sought in the different tissues for evidence of the secondary products of the oxidation of alcohol, for aldehyde acetal, acetic acid, and they found none of those products, except some acetic acid in the stomach, which acid they concluded was formed from the alcohol received directly into the stomach, and from the action exerted upon it there by the gastric juice. The experiments carried on by these inquirers were so numerous and careful, and the results they arrived at were so definitively stated, their labours were for a season accepted as conclusive by many men of science, and by the majority of the public. It was ascertained by other experimentalists that alcohol is eliminated by the system in the direct way, as alcohol, and the question of elimination rested as if it had been solved.

The interval of credence in these assertions was not very prolonged. An English physician soon commenced to cross a lance with his learned French peers, and to point out certain distinct errors in their results. I have no doubt many of you know, before I mention his name, that he to whom I refer was the physician who last year lost his life from the performance of his professional duties—the late Dr. Anstie. Respecting this observer, whose friendship I owned for many years, it is meet for me to pay this public tribute of respect; that no man I ever knew combined with vigour of mind such incomparable industry and courage, or a more honourable regard for scientific truth and honesty. The subject we are now considering has lost no investigator more ably learned for the work that still remains to be done.

* Cantor Lectures: delivered during December, 1874, and January, 1875, from the *Journal of the Society of Arts.*

From Dr. Anstie came the earliest expression of doubt relative to this hypothesis of what is called the direct elimination of alcohol by the secretions, and from him have come the latest objections. His arguments have been sustained abroad by Schulinus, and in this country by Drs. Thudichum and Dupré, whose work on wine will, even in another century, be more highly prized, if that be possible, than it is now. The sum and substance of the labours of these observers is stated in a few words. They prove that while it is true that, under certain circumstances, alcohol taken into the body will pass off in the secretions unchanged, the quantity so eliminated is the merest fraction of what has been injected, and that there must be some other means by which the spirit is disposed of in the organism. In a lecture I delivered on this subject in the year 1869, I ventured to suggest, in commenting upon a series of Dr. Thudichum's remarkable researches that perhaps one element of research was wanting to prove conclusively the fallacy of the direct elimination hypothesis. I thought that sufficient time had not been allowed between the administration of the spirit and the final determination made for it in the excreted fluids. It was not, I argued, shown how much spirit the tissues would hold unchanged. The objection was sound, and it has been renewed by more recent experiment.

In the last research conducted by Anstie, in which he was assisted by Dupré, the results of the experiments were unmistakable in their bearing on the points now under our consideration. The history of these labours is recorded in full in the last paper written by Dr. Anstie, and published in the journal called the *Practitioner*, for July, 1874.

The test that had been commonly employed for determining the presence of alcohol in the fluid suspected of containing it, was the colour test. A solution is made of bichromate of potassa, with sulphuric acid. When to this solution alcohol is added, there is a change of colour from the brownish red to green; owing to the reduction of the chromic acid to the green oxide of the base chromium. By marking the difference of colour produced a scale can be adopted, which will show the extent of the reduction, and thereby the amount of the spirit that has caused the change. This process was improved by Dr. Dupré. He distilled the fluid in which alcohol was believed to be present, and then after treating the distillate with the bichromate and sulphuric acid solution, he tested with a standard solution of soda for the amount of acetic acid which would be produced by the oxidation of alcohol were that fluid present.

This modification of test was and is a very considerable advance, since it enabled the observers to conduct their determinations with greater accuracy of detail. In the research they conducted with it two facts of singular interest were elicited. The first fact was discovered by Dr. Dupré. It was, that from the secretions of persons who do not drink alcohol at all a fluid can be distilled which affects the chromic test as if alcohol were actually present in the secreted fluids, and that this hitherto unsuspected product is oxidized into an acid so like acetic acid it cannot be distinguished from it, and is apparently identical with it. To be plain, Dr. Dupré's discovery suggests that no man can be, in strict scientific sense, a non-alcoholic, inasmuch as " will he nill he "—he brews in his own economy a " wee drap." It is an innocent brew certainly, but it is brewed, and the most ardent abstainer must excuse it. " Argal, he that is not guilty of his own death shorteneth not his own life." The fault, if it be one, rests with nature, who, according to our poor estimates, is no more faultless than the rest of her sex.

The second fact, which came chiefly from the labours of Dr. Anstie, was that from animals under alcohol, not one of the secretions, not all the secretions combined, yielded any more than a fractional amount of the alcohol that had been administered. The experiments were by necessity made on the inferior animals, but they supplied none the less conclusively the fact stated. It was proved that an animal, a terrier dog, weighing 10 lbs. could take with comparative impunity nearly 2000 grains of absolute alcohol in ten days, and that on the last day of this regimen he only eliminated by all the channels of elimination 1·13 grains of alcohol. This fact was of itself sufficiently remarkable, but another still more important remains to be told. In completion of his research after an animal had been treated with alcohol, as above described, Anstie killed it, instantly and painlessly, two hours after it had received the last quantity—95 grains—of spirit. Then the whole body, including every fragment of tissue with all the fluid and solid contents, was subjected to analysis, with the result of discovering only 23·66 grains of spirit.

We are driven by the evidence now before us to the certain conclusion that in the animal body alcohol is decomposed; that is to say, a certain portion of it (and if a certain portion why not the whole?) is transmutable into new compounds. The inference that might be drawn is fair enough that the alcohol is lost by being burned in the body. It is lost in the body, and out of the body it will burn. If it will burn in the organism it will supply force, for it enters as the bearer of so much potential energy. In combining with oxygen is there then a development of force or heat to the extent that would be developed in the combustion of the same quantity in the lamp, or from the distribution of it over the platinum black? At the same time, and in corroboration, is that product of its combustion, carbonic acid, to be discovered in the excretions? If there be heat, and if there be product of carbon consumed in oxygen, then alcohol must rank as a heat-forming food.

Does Alcohol Increase the Animal Heat?

In putting before you this inquiry, I am prepared to answer it by direct knowledge gained from individual experiment. In the course of some researches I had to make for reports rendered to the British Association for the Advancement of Science, it became part of my duty to ascertain what effect certain chemical agents exert over the animal temperature. Amongst these agents was alcohol.

At the time when my researches commenced, viz., in the year 1864, there was nothing definitely known on the subject. The thermometer was not then in such general use as it is now, and it had not been applied, as far as I know, to this particular determination. Generally, however, it had been assumed by the majority of persons that alcohol warms the body, and to " take just a drop to keep out the cold " had been the practice which the experience of ages seemed to justify. It is fair, at the same time, to say that Dr. Lees, and some other far-seeing observers, had for many years held and asserted a different view. They had not entered into minuteness of experimental detail, but they had observed from the effects of alcohol on those who had been exposed to cold in the extreme North and in other regions of ice and snow, that the drinkers did not live on like other men. Thus, in so far as I had what is called experience to guide me, I found conflict of opinion. It was not my business, however, to accept guidance of this kind, but to appeal to the only safe guide, the direct interrogation of nature by experiment.

It were impossible for me to recount the details of the long research—extending, with intervals of rest, for three years—which was conducted in my laboratory, to determine the influence of alcohol on the animal temperature. The effects were observed on warm-blooded animals of different kinds, including birds; on the human subject in health, and on the same subject under alcoholic disease. Similar experiments were made in different external temperatures of the air, ranging from summer heat to the degrees below freezing point. The whole were carried on from experiment to experiment, without regard either to comparison or result until the general character of result began to proclaim that a rule existed which could hardly be considered exceptional. The facts obtained I may epitomize as follows:—

The progressive stages of change of animal function from alcohol are four in number. The first is a stage of excitement when there exists that relaxation and injection of the blood vessels of the minute circulation with which we have become conversant. The second is the stage of excitement with some muscular inability and deficient automatic control. The third is a stage of rambling, incoherent, emotional excitement, with loss of voluntary muscular power, and ending in helpless unconsciousness. The fourth and final stage is that in which the heart itself begins to fail, and in which death in extreme instances of intoxication closes the scene. These stages are developed in all the warm-blooded animals, and the changes of temperature throughout the whole are relatively the same.

In the first stage the external temperature of the body is raised. In birds—pigeons—the rise may amount to a full degree, on Fahrenheit's scale; in mammals it rarely exceeds half a degree. In man it may rise to half a degree, and in the confirmed inebriate, in whom the cutaneous vessels are readily engorged, I have seen it run up to a degree and a half. In this stage the effect on the extremities of the nerves is that of a warm glow, like what is experienced during the reaction from cold.

The heat felt in this stage might be considered as due to the combustion of the alcohol; it is not so; it is in truth a process of cooling. It is from the unfolding of the larger sheet of the warm blood and from the quicker radiation of heat from that larger surface. During this stage, which is comparatively brief, the internal temperature is declining; the expired air from the lungs is indicating, not an increase, but the first period of reduction in the amount of carbonic acid, and the reddened surface of the body is so reduced in tonicity that cold applied to it increases the suffusion. It is this most deceptive stage that led the older observers into the error that alcohol warms the body.

In the second stage, the temperature first comes down to its natural standard, and then declines below what is natural. The fall is not considerable. In birds it reaches from one and a half to two degrees. In other animals, dogs and guinea pigs, it rarely exceeds one degree; in man it is confined to three-fourths of a degree. In a room at the temperature of 65° or 70° the decrease of temperature may not actually be detected, but it is quickly detected if the person in whom it is present pass into a colder atmosphere, and it lasts, even when the further supply of alcohol is cut off, for a long period, viz., from two and a half to three hours. It is much prolonged by absence of food.

During the third degree the fall of temperature rapidly increases, and as the fourth stage is approached it reaches a decline that becomes actually dangerous. In birds the reduction may be five degrees and a half, and in the other animals three. In man it is often from two and a half to three degrees. There is always during this stage a profound sleep or coma, and while this lasts the temperature continues reduced.

It is here worthy of incidental notice that, as a rule, the sleep of apoplexy and the sleep of drunkenness may be distinguished by a marked difference in respect to temperature. In apoplexy the temperature of the body is above, in drunkenness below, the natural standard of 98° of Fahrenheit's scale.

Under favourable circumstances a long period is required before the body recovers its natural warmth after such reduction of heat as follows the extreme stage of alcoholic intoxication. With the first conscious movements of recovery there is a faint rise, but such is the depression that these very movements exhaust and lead to a further reduction. I have known as long a period as three days required, in man, to bring back a steady natural return of the full animal warmth.

Through every stage, then, of the action of alcohol—barring that first stage of excitement—I found a reduction of animal heat to be the special action of the poison. To make the research more perfectly reliable, I combined the action of alcohol with that of cold. A warm-blooded animal, insensibly asleep in the third stage of alcoholic narcotism, was placed in a chamber—the air of which was reduced in temperature to ten degrees below freezing point—together with another similar animal which had received no alcohol. They both sleep under these circumstances, but the alcoholic sleeps to die; the other simply sleeps more deeply than is natural, sleeps and lives so long as the store of food it is charged with continues to support life. Within this bound it awakes, in a warmer air, uninjured, though the degree of cold be carried even to the act of freezing of the extreme parts.

One more portion of evidence completes the research on the influence of alcohol on the animal temperature. As there is a decrease of temperature from alcohol, so there is proportionately a decrease in the amount of the natural product of the combustion of the body. The quantity of carbonic acid exhaled by the breath is proportionately diminished with the decline of the animal heat. In the extreme stage of alcoholic insensibility—short of the actually dangerous—the amount of carbonic acid exhaled by the animal and given off into the chamber I constructed for the purposes of observations was reduced to one-third below the natural standard. On the human subject in this stage of insensibility the quantity of carbonic acid exhaled has not been measured. But in the earlier stage of alcoholic derangement of function the exhaled gas was measured with much care by another earnest worker, whose recent death we have also to deplore—Dr. Edward Smith. In these early stages Dr. Smith found that the amount of carbonic acid was reduced in man, as I have found it in the lower animals, so that the fact of the general reduction may be considered as established beyond disputation.

We are landed then at last on this basis of knowledge. An agent that will burn and give forth heat and product of combustion outside the body, and which is obviously decomposed within the body, reduces the animal temperature, and prevents the yield of so much product of combustion as is actually natural to the organic life.

What is the inference? The inference is that the alcohol is not burned after the manner of a food which supports animal combustion, but that it is decomposed into secondary products, by oxidation, at the expense of the oxygen which ought to be applied for the natural heating of the body.

For some time to come the physiological world will be studiously intent on the discovery of the mode by which alcohol is removed from the organism. It is a subject on which I shall one day be able to speak, I hope, with some degree of experimental certainty, but on which at this moment I am not prepared to offer more than an indication of the probable course of research. I may venture to add, in advance, two or three suggestions to which my researches, as far as they go, point.

Firstly, I believe there is a certain determinable degree of saturation of the blood with alcohol, within which degree all the alcohol is disposed of by its decomposition. Beyond that degree the oxidation is arrested, and then there is an accumulation of alcohol, with voidance of it, in the unchanged state, in the secretions.

Secondly, the change or decomposition of the alcohol in its course through the minute circulation, in which it is transformed, is not into carbonic acid and water, as though it were burned, but into a new soluble chemical substance, probably aldehyde, which returns by the veins into the great channels of the circulation.

Thirdly, I think I have made out that there is an outlet for the alcohol, or for the fluid product of its decomposition, into the alimentary canal, through the secretion of the liver. Thrown into the canal it is, I believe, subjected there to further oxidation, is in fact oxidized by a process of fermentation attended with the active development of gaseous substances. From this surface the acid product is in turn reabsorbed in great part and carried into the circulation, and is disposed of by combination with bases or by further oxidation.

Here, however, I leave the theoretical point to revert to the practical; and the practical is this, that alcohol cannot by any ingenuity of excuse for it, be classified amongst the foods of man. It neither supplies matter for construction nor heat. On the contrary, it injures construction and it reduces temperature.

Effect on Muscular Power.

Behind the question of the effect of alcohol upon the animal temperature was another subject for inquiry. It was fair to ask whether, if heat were not produced by it, some additional stimulus might be communicated by the spirit to the muscular fibre. There is nothing in what we see relating to the action of alcohol in man that would lead us to suppose it capable of giving an increased muscular power, and it is certain that animals subjected even for short periods of time to its influences lose their power for work in a marked degree. Indeed, if we were to treat our domestic animals with this agent in the same manner that we treat ourselves, we should soon have none that were tameable, none that were workable, and none that were edible. I thought it, nevertheless, worth the inquiry whether at any stage of the alcoholic excitement living muscle could be induced to show an extra amount of power; I therefore submitted muscle to this test. I gently weighed the hinder limb of a frog until the power of contraction was just overcome; then by a measured electrical current I stimulated the muscle to extra contraction, and determined the increase of weight that could thus be lifted. This decided upon in the healthy animal, the trial was repeated some days later on the same animal after it had received alcohol in sufficient quantity to induce the various stages of alcoholic modification of function. The result was that through every stage the response to the electrical current was enfeebled, and so soon as narcotism was developed by the spirit, it was so enfeebled that less than half the weight that could be lifted in the previous trial by the natural effort of the animal could not now even be raised under the electrical excitation.

In man and in animals, during the period between the first and third stages of alcoholic disturbance, there is often muscular excitement, which passes for increased muscular power. The muscles are then truly more rapidly stimulated into motion by the nervous tumult, but the muscular power is actually enfeebled.

Hygienic Considerations.

The facts I have endeavoured to lay before you in this as well as in the last lecture will suggest to your minds many thoughts bearing upon the health of individuals and communities, in so far as health is affected by the potent agent, alcohol. I heed hardly, indeed, presume to offer any suggestions, but one or two of a specially practical and everyday character may be ventured.

I am bound to intimate that the popular idea of administering alcohol for the purpose of sustaining the animal warmth is an entire and dangerous error, and that when it is brought into practice during extremely cold weather it is calculated to lead even to fatal consequences, from the readiness with which it permits the blood to become congested in the vital organs. I cannot too forcibly impress the fact that cold and alcohol act, physiologically, in the same manner, and that, combined in action, every danger resulting from either agent is doubled.

Whenever we see a person disposed to meet the effects of cold by strong drink it is our duty to endeavour to check that effort, and whenever we see an unfortunate person under the influence of alcohol it is our duty to suggest warmth as the best means for his recovery. These facts prompt many other useful ideas of detail, in our common life. If, for instance, our police were taught the simple art of taking the animal temperature of those persons whom they find in the streets in a state of insensibility, the results would be most beneficial. The operation is one that hundreds of nurses now carry out daily, and applied by our police-officers it would enable them not only to detect the difference between a man in an apopletic fit and a man intoxicated, but would suggest naturally the instant abolition of the barbarous practice of thrusting the really intoxicated into a cold and damp cell, which to such a one is actually an anteroom to the grave.

Once more: I would earnestly impress that the systematic administration of alcohol for the purpose of giving and sustaining strength is an entire delusion. I am not going to say that occasions do not arise when an enfeebled or fainting heart is temporarily relieved by the relaxation of the vessels which alcohol, on its diffusion through the blood, induces; but that this spirit gives any persistent increase of power by which men are enabled to perform more persistent work is a mistake as serious as it is universal.

Again, the belief that alcohol may be used with advantage to fatten the body is, when it is acted upon, fraught with danger. For if we could successfully fatten the body we should but destroy it the more swiftly and surely; and as the fattening which follows the use of alcohol is not confined to the external development of fat but extends to a degeneration through the minute structures of the vital organs, including the heart itself, the danger is painfully apparent.

In conclusion, whatever good can come from alcohol, or whatever evil, is all included in that primary physiological and luxurious action of the agent upon the nervous supply of the circulation to which I have endeavoured so earnestly to direct your minds. If it be really a luxury for the heart to be lifted up by alcohol; for the blood to course more swiftly through the brain; for the thoughts to flow more vehemently; for words to come more fluently; for emotions to rise ecstatically, and for life to rush on beyond the race set by nature; then, those who enjoy the luxury must enjoy it—with the consequences.

Parliamentary and Law Proceedings.

Attempted Poisoning by Red Precipitate.

At the Somerset Assizes, held at Taunton, on Saturday March 27, Sarah Ann Cross, 16, labourer, was indicted for feloniously administering red precipitate of mercury to George Cross, her father, with intent to murder him, at Winsford, on the 17th February. Mr. Warry, who prosecuted, stated in his opening, that the prosecutor worked for a farmer named Liddon. His wife died about three years ago, and since then the prisoner had been his housekeeper. On the 16th of February, Mr. Milton, a miller, told the prosecutor there was 2*s.* owing for grinding corn. Cross had given his daughter the money to pay for it, and asked her what she had done with it. She insisted that she had paid for the grinding, and he told her that she was telling falsehoods, but nothing further happened. Next day the prisoner sent her niece, a child seven years old, to the field with her father's dinner of fried potatoes, but he had no sooner tasted the food that he was sick and vomited, and so was a man named Pope, who also tasted the potatoes. Cross put the potatoes back, and took them home, and on the food being analysed, red precipitate was found in it. When the prosecutor came home the prisoner left the house, and did not return. She was, however, apprehended three days afterwards. On the day the poison was found in the food the prisoner had gone to Bridgetown and purchased some red precipitate. The packet was labelled "Poison."

Mr. W. W. Stoddart, of Bristol, the county analyst, proved the presence of red precipitate on the plate and knife used by the prosecutor.

The prisoner, who shed tears copiously during the trial, merely stated in her defence that she "did not do it." In summing up, the learned commissioner said it seemed to him a very dangerous thing for a young girl like the prisoner to be allowed to purchase such a deadly poison without much inquiry. The prisoner was found guilty of administering the poison with intent to do grievous bodily harm, and sentenced to seven years' penal servitude.—*Daily Bristol Times.*

Supposed Poisoning by Colocynth.

Mr. C. C. Lewis, coroner, has held an inquiry at West Ham, touching the circumstance of the death of Fanny Sharp, of Plaistow Grove, West Ham, who died from the effects of colocynth, or bitter apple. The following evidence was adduced :—

Sarah Whitehead, a married woman, living at West Ham, deposed : I have known deceased seven months. I acted as midwife to deceased last October. The child is still alive. Deceased has not been able to suckle it, she having been in a very weak state. She was the wife of James Sharp. Deceased sent for me on Sunday morning. She was retching and purged, and was very weak. She told me she had brought it on herself, as she had taken two-pennyworth of bitter apple. Up to Sunday afternoon she had not ceased retching and purging, and she believed she was going to die. She took it because she believed she was pregnant, and she did not want to have any more children. I remained with her half an hour, and saw her again in the afternoon. She was very bad, and I remained with her till a doctor came. On Monday morning she died, about twelve.

Mary Tyler, a child of deceased, thirteen years of age, deposed : She was sent to the chemist's on Saturday morning last for two-pennyworth of bitter apple, and she was served by the assistant. It was a powder in paper ; it had "bitter apple" written upon it. Nothing was written upon it as to how much was to be taken. Her mother took it in water about half-past seven. Father did not know anything about it. Just after, she and her father went to Stratford, and returned about ten. Her mother was in bed. Her mother said the bitter hung about her mouth, and she was retching. She heard her mother retching in the night and during Sunday.

Mr. Price, assistant to Dr. Levick, deposed : Dr. Levick was sent for at half-past four on the Sunday afternoon. He was ill in bed and unable to leave his room, and at five I went and saw deceased. She was in bed, retching violently, and severely purged, and very prostrate ; extremities cold and pulse very weak. She told me she had not taken anything, and in answer to me said she had gone a week over the month. The midwife told me deceased had taken two-pennyworth of bitter apple, and that explained her symptoms. Bitter apple is a powerful purgative. The proper dose was from two to eight grains, and in her condition she should have taken no more than five grains, and she took about 120 grains. There is no doubt that she died from exhaustion from the effects of an overdose of the bitter apple. I prescribed chlorodyne.

Thomas Samuel Minett, assistant to Mr. Cowles, chemist, Stratford, deposed : I sold some bitter apple last week to a child. The child asked for bitter apple. I did not ask her what it was for. Two-pennyworth would be a quarter of an ounce ; less than 120 grains. The dose is from two to eight grains ; five or six grains is the ordinary dose, eight grains the maximum. "Bitter apple" was written on the paper, but no directions or dose. Scarcely a chemist in Europe has a label printed for bitter apple, and I think no one would have directions. It would be a most difficult thing to draw a line with regard to the dose. It is neither necessary nor customary to put on a label with directions.

The Coroner said he considered it right that directions should be on the paper.

Foreman of the Jury : Do you think it right to sell it in that way, without asking what it is for ?

Witness : Most certainly. I do not question people except for actual poisons.

Coroner : There is no law to compel them to label it or make any inquiries.

Juryman : Is it used for anything else ?

Witness : Yes, for moth, but not at this time of the year.

Juryman : Would it hurt you to take a pennyworth ?

Witness : You would run the risk.

Juryman : Because I have known women take a pennyworth.

The Coroner, in summing up, remarked that the woman was very weak, in fact, in the last stages of consumption ; and believing she was in the family-way, having gone over her monthly period, she sent for the bitter apple, and as no one knew of her taking it, she alone was responsible for her death. A verdict was returned in accordance with the evidence.

A Fatal Prescription for Gout.

William Carrick, aged 58 years, residing at Croydon, was admitted into the Croydon General Hospital on the 15th ult., under the care of Dr. Adams, with symptoms of irritant poisoning. It appeared, from the statement of his wife, that in order to relieve an attack of gout he took a wine glassful of a mixture made by himself from a receipt given to him by a friend. The ingredients were to be three-pennyworth of potass, two-pennyworth of flowers of sulphur, and two grains of the best gunpowder. Carrick sent a child out to different places for each ingredient, and for the potass the child went to an oil-shop, where, instead of iodide of potass (which was intended), common caustic potash was given. When taken to the hospital everything was done by the resident house surgeon, Dr. Ilott, in the way of antidotes, and Carrick lingered on until Sunday, when he sank from inflammation of the bowels, caused by the caustic alkali he had swallowed.—*Standard.*

Obituary.

DANIEL HANBURY, F.R.S., etc.

By the sudden death of Mr. Daniel Hanbury in the prime of life, pharmacology and the allied sciences in their relation to pharmacology have lost one of their most assiduous and successful students, and deep will be the sense of personal loss of very many engaged in the same studies both at home and abroad. As a frequent contributor to this Journal the character and value of his work has long been known to our readers, and the following particulars of his life, though unavoidably fragmentary, will be read with interest.

Daniel Hanbury was born 11th September, 1825. He was the eldest child of Daniel Bell Hanbury, who for many years was a valued member of the Council of the Pharmaceutical Society, and for eleven years its Treasurer. In early life he showed superior ability. At school he always maintained a foremost place, and attained a considerable degree of proficiency in classical studies, and also in water-colour drawing.

In the year 1841 he commenced his business training under the firm of Allen, Hanburys and Barry, of which his father was an active member. Here his peculiar abilities were speedily manifested and appreciated.

His innate love of precision and accuracy were stimulated by the example and influence of Mr. Barry;* he became an exquisitely neat experimenter, and his handwriting assumed the form which those familiar with it will never forget, combining in a singular degree, firmness, force of character, and complete accuracy of detail.

---

* See *Pharm. Journ.*, July, 1864.

Whatever he undertook was done with uncompromising thoroughness. He never spared himself any labour, nor sought the notice of those around him by talking of any effort he made, but quietly brought his fine abilities to bear with painstaking conscientiousness on the one matter immediately before him, whether dispensing a prescription, posting an account book, or writing à scientific paper. With such qualities he not only accomplished a very large amount of work, but the quality of what he did was almost faultless.

In the year 1844 he studied at the laboratory of the Pharmaceutical Society.

His pursuits early brought him in contact with the late Dr. Pereira who treated him with great consideration, and a warm friendship sprang up between the professor and his pupil, which lasted till the death of the former, and the remembrance of which has since often been manifested by Mrs. Pereira. His first contribution to this Journal was we believe on "Turnsole," in January, 1850. From that time to the present his papers are scattered thickly through our volumes, numbering, according to the index, sixty-one, the last being incorporated in an article entitled "Cinchona or Chinchona," published on the 13th of February in the present year.

The series of papers on Chinese Materia Medica, published in the years 1860-1-2 were highly esteemed by those most capable of appreciating them and afford a characteristic example of accurate and careful research.

He never wrote without having original information to impart, and his papers uniformly bear evidence of careful investigation and thorough knowledge.

Most happily the work upon which he had been engaged for many years in conjunction with Professor Flückiger, the 'Pharmacographia,' was completed and published last year. This work is a storehouse of reliable information to which future generations will have recourse, and it is by his part in this important work that he will hereafter be best known. No one can read the historic sections of the book without being struck by the vast variety and extent of reading to which they bear witness.

Narratives of travels were especially attractive to him. He took nothing at second hand, but always sought his information from the fountain head. His library contained many Latin volumes of the early Portuguese, Dutch, and Spanish voyagers, to which he constantly referred, and he eagerly read modern books of travel likely to throw light on his favourite studies.

Whilst alluding to his writings we must not omit to mention the important part he took in the preparation of the Pharmacopœia of India, a work involving much labour. He was also one of those deputed to draw up the Admiralty manual of scientific inquiry. Botany was the science to which he especially devoted his attention. He contributed to the *Transactions of the Linnean Society* the following papers, "Note on Cassia Moschata," H. B. et K., xxiv, 161; "On the Species of Garcinia which affords Gamboge in Siam" (G. Morella), xxiv. 487, and with Mr. Currey, "Remarks on Sclerotium Stipitatum and Similar Productions," xxiii, 93; and numerous papers by him will be found in the *Journal of the Linnean Society.*

We believe he has collected a large mass of original information for a monograph on an important genus, and trust it may yet be given to science.

Occasionally he contributed an article to the literary periodicals. A paper containing curious information on Frangipani in *Notes and Queries*, and another on the botanical origin and country of Myrrh, published in *Ocean Highways*, for April, 1873, will be remembered by some of our readers. He occasionally contributed to the *Athenæum*, and a review of "The Countess of Cinchon and the Cinchona Genus" is about to appear in the *Academy.* He served on the juries of the International Exhibitions in 1862 and in 1867, and in the former year acted as secretary to the jury on vegetable products, the proceedings of which were conducted in French. In the year 1855 he was elected a Fellow of the Linnean Society, repeatedly served on its Council, and held the office of Treasurer at the time of his death.

He was also a Fellow of the Chemical Society, and Member of its Council in the year 1869.

In the year 1867, on his first nomination, he was elected a Fellow of the Royal Society, and a Member of its Council in 1873.

Of the Pharmaceutical Society he was a warm supporter almost from its origin. For many years (from June, 1860, to May, 1872,) he rendered very valuable services as an examiner, often at great personal inconvenience, and he was a very constant attender of the evening meetings, to the usefulness of which he often contributed.

In 1870 he retired from business. He never married, but lived with his parents, to whom he was a most kind and affectionate son. Though possessed of ample means, his habits, we believe, both from principle and taste, were remarkably simple and inexpensive. He disliked and shunned everything approaching ostentation, and luxury and self-indulgence were utterly alien to his life. He was always an early riser, and habitually got through an important amount of work in his library before breakfast, and few indeed were the moments wasted from early morning until he again retired to rest.

Travelling on the Continent was one of his greatest pleasures. He read German. He had some knowledge of Italian, but he spoke French almost as a native, and hence travelling in France was specially attractive to him. It was not only in Paris, where the late Professor Guibourt and other scientific friends always gave him a warm welcome, but in the provincial towns and in the cities of the South wherever there was a botanist of standing he found an open door and often gained an acquaintance who became a valued correspondent able to afford local or other special information.

But his journeys were not confined to France. In the year 1860 he visited the Holy Land with Dr. Hooker, and of late years he frequently spent considerable time at a residence belonging to a brother near Mentone. Here he took great delight in introducing into the beautiful gardens the vast variety of interesting plants which can there be acclimatized.

During these journeys he frequently exercised his skill in water-colour drawing, and the productions of his pencil, like those of his pen, always possessed the rare merit of *truthfulness*, whilst a thoroughly artistic effect was preserved. The same exquisite delicacy of touch was apparent in his drawing, writing or printing, or forming of Arabic, Chinese, or other complicated characters.

In his frequent travels he seemed to have acquired something of the continental practice of using but little meat in proportion to the vegetable food taken. His diet was always spare, and it may be doubted whether his health did not suffer from the abstemiousness of his habit of living, coupled with the constant strain to which he subjected his mental powers. But if this was so the motive was never the gratification of ambition or other unworthy object, but the pure love of action and desire rightly to use the powers bestowed upon him. No feature of his life was in fact more striking than his freedom from that anxious self-assertion which too often disfigures the characters of men of science. Whilst remarkably self-reliant, he never sought to thrust himself into notice, but rather kept out of view until drawn out by those who had learned his worth. Though never robust, his health rarely impeded his activity, and slight ailments were resolutely disregarded. There were no indications of approaching illness until he was attacked with a severe *rigor* about the 6th of March; this was followed by serious inflammation of the mouth, and on the subsidence of this local affection symptoms of typhoid fever appeared. On the 18th his condition first caused serious alarm. With little apparent change his strength gradually failed till the evening of the 24th, when he peacefully passed away.

Long will the memory of his fine, thoughtful features and spare frame dwell with many who have known and valued him, and long will they continue to miss the decided tones in which his clear judgment and exact knowledge were unhesitatingly expressed. With him every benevolent object connected with science or scientific men has lost a munificent supporter.

Mr. Hanbury remained to the last a member of the Society of Friends, amongst whom he had been brought up. With characteristic reticence he scarcely ever alluded to his own religious experience, but his habits of devotion, and an occasional expression, afford evidence of the reality of his Christian faith.

That a man thus endowed with talents both natural and acquired should be taken away ere he completes his fiftieth year, is to us an inscrutable mystery. The light of eternity alone can reveal the full significance of any life.

Notice has also been received of the death of the following:—

On the 23rd January, 1875, Mr. Alfred Glew, Chemist and Druggist, of Peterborough, aged 31.

On the 28th March, 1875, Mr. Joseph Sarjeant, Chemist and Druggist, of Ramsey, Hunts.

Pharmacy in Ireland.

Sir,—Having been shown a letter in your Journal of the 20th inst., signed by Mr. William Hayes, and written by him in reply to what I consider a truthful and very sensible communication from Mr. Charles H. Hartt, in your issue of the previous week, I venture to offer a few observations on the subject.

I must characterize the letter of Mr. Hayes as, to use the mildest phrase, disingenuous and calculated to perpetuate the erroneous ideas which seem to prevail in England generally with reference to Irish Pharmacy.

The term "chemist and druggist" is, I assert, utterly inapplicable to druggists in Ireland; they are not entitled to the name, since they have not passed an examination in chemistry, nor are they "dispensing chemists" as the words are applied in England, for they have never been legally entitled to practise as such. There is no analogy whatever between the Irish "druggist," and the English "chemist." The apothecaries of Ireland are the only legal dispensing chemists, and although hitherto required to undergo a medical and surgical as well as a thorough pharmaceutical training, a large number confine their attention solely to the practice of pharmacy; hence I maintain that the pure pharmacist is not "almost extinct." Those apothecaries who practise medicine nearly all possess some other medical qualification in addition, on the strength of which they act as general practitioners.

Allow me also to state distinctly that the general feeling of the Irish apothecaries is that the future pharmacists of the country should correspond in qualification and education to the gentlemen who have passed the "Major" of the Pharmaceutical Society of Great Britain. The mistake of the Apothecaries' Hall has been the persistence in the desire to grant a single qualification in medicine as well as in pharmacy, consequently the standard has been unnecessarily high; but this affords no reason for going to the other extreme and making it too low.

Mr. Hayes can record "no accident to the public which has occurred in Ireland through the ignorance or incompetence of any druggists or their assistants." Two instances recur to my mind as having occurred in this town recently; in one, extract of belladonna was vended by the druggist by mistake for extract of taraxacum, in the other, a coroner's jury found that death resulted from poisoning by a powder, obtained from a druggist's shop as a seidlitz powder.

An Irish Apothecary.

Belfast, March 25, 1875.

Sir,—I have read with interest the somewhat spasmodic correspondence which has appeared at various times in the pages of this Journal on the above subject. Having read your last leader on the subject, I must, with Mr. C. H. Hartt, express my regret and surprise at its tone, and while fully sympathizing with your desire to free the pharmacists from the trammels of the medical profession, must respectfully decline to take a "leap in the dark." As an Englishman I feel ashamed to find my brother pharmacists in England and Scotland continue to hold such obtuse and misty notions on Irish pharmaceutical matters. Though cordially agreeing with you on the desirability of the overthrow of the Apothecaries' Hall dynasty and the establishment in its stead of a Pharmaceutical Society, I emphatically protest against the suggestion of allowing the *quasi* druggists of Ireland to form unreservedly the nucleus of such a society. That the weak *régime* of the Apothecaries' Hall of Ireland should terminate every one interested in the progress of pharmacy in Ireland must acknowledge; for it has not only neglected the interests of its licentiates, but has failed also to do its duty to the public.

As you seem to hold such a high opinion of the dispensing abilities of the druggists of Ireland, and it is very important at the present juncture for pharmacists across the Channel to have a clear apprehension of the present position of the Irish druggist, it will be well to explain his position, so that it may be compared with the position of the British druggist before the Act of 1868.

In Ireland then, at the present time, anyone can assume the title of chemist and druggist and can open shop for the sale of drugs and indiscriminate sale of poisons in spite of the provisions of the Sale of Poisons (Ireland) Bill, but not for the dispensing of medicines. In Great Britain, as you are well aware, the chemist and druggist was in a similar position with regard to the opening of shop, and sale of drugs and poisons, but he was not debarred from dispensing medicines. In this lies the important distinction between the two. The British druggist had a dispensing status which no legislature could deprive him of, the Irish druggist does not possess that status, and has, therefore, not a tittle of claim to it.

In consequence of this restriction, which has been in force for nearly a century, the Irish druggist is not much better able to perform the function of dispensing medicines with either advantage to himself or with safety to the public than the drug-selling grocer or doctor's errand boy in England is.

If the Pharmaceutical Society of Great Britain should unduly favour the approaching legislation they will strike a serious blow at high-class pharmacy in Ireland, and will do dishonour to the name of their glorious founder, Jacob Bell.

The Irish pharmacist-apothecaries (if I may so term them) have done much to raise pharmacy in Ireland to the high position it now enjoys, and this they have been enabled to do on account of the long early training and rigid examinations they have had to undergo. The examinations they have to pass, excluding medical subjects, are similar to those of the pharmaceutical chemists in Great Britain with the superior safeguard of having to serve a seven years' apprenticeship. One of the main arguments used by the agitators in this "levelling up" process in pharmacy is that there is an insufficient number of such high-class pharmacists, and there is consequently a great dearth of, and pressing demand for additional dispensing facilities. So far as I have been able to learn during a ten years' sojourn in Ireland there is very little demand (at any rate on the part of the public, who, I presume, are the best judges) for increased dispensing facilities.

To my mind a Pharmacy Bill for Ireland is as much required to regulate certain irregularities which have been allowed to obtain during the weak *régime* of the Apothecaries' Hall, and for the assimilation of the practice of pharmacy in the United Kingdom, as to provide the public with more dispensing accommodation.

The Pharmaceutical Society of Great Britain, by means of the increased stringency of their examinations, are thinning the number of pharmacists throughout the country; by supporting the claims of the Chemist and Druggists' Society of Ireland they will adopt a different policy here where wealth less abounds, and where prices are proportionately lower than in the sister kingdom.

The establishment of a Pharmaceutical Society for Ireland ought therefore to be proceeded with circumspectly.

The apothecary of Ireland should take the rank of pharmaceutical chemist, and should occupy a similar position in its constitution to that of the pharmaceutical chemist in the British Society.

The chemist and druggist should, on passing, not a Modified, but the new Minor examination of the Pharmaceutical Society, be entitled to the same privileges as the British chemist and druggist. It is the duty, alike imperative on the Pharmaceutical Society and the Irish apothecary, that nothing short of the new Minor examination should admit any Irish chemist and druggist to the privileges now enjoyed by the British. Anything less than that would lower the status of Irish pharmacy, and would be fraught with danger to the public safety.

While speaking of the public safety I cannot close this letter without adverting to the very coarse allusion to a very grave dispensing error, by the Honorary Secretary of the Chemist and Druggists' Society in your last issue. If that is a sample of the language we may expect in the Council chamber of the proposed society, I fear we shall have to make immense progress in pharmaceutical ethics before we are abreast of our English brethren.

Without going very deep into the matter, I may remark that the druggist in Ireland presents a perfect type of a correct dispenser. In this line he is almost infallible, simply for the reason that he has nothing to dispense. The Honorary Secretary of the Chemist and Druggists' Society has certainly a wonderfully convenient memory, but if he will only leave the compounding department and recall to his recollection the numerous errors made by his class in the mere retailing of drugs he must certainly come to the conclusion that the results would be appalling if they were allowed to meddle and muddle in the compounding department without let or hindrance.

A Pharmaceutical Chemist in Ireland.

March 25, 1875.

[*** We have also received from Mr. Hayes a long letter on this subject, the publication of which would, we think, serve no useful purpose.—Ed. Ph. J.]

Pharmaceutical Remuneration.

Sir,—One of my customers informs me on indisputable authority (for he encloses the bill of charge) that he is supplied with a belladonna plaster of the Pharmacopœia, spread on leather, six by eight inches in size, for sixpence. With emp. belladonnæ, B. P., quoted at 7*s*. per lb., and plaster skins at 20*s*., 30*s*., to 36*s*. per dozen, can you, or any of your correspondents, explain how this clever picce of business can be performed?

A Perplexed Druggist.

Saccharated Calomel.

Sir,—Several years ago I brought under the notice of one of the makers of teething powders the case of a poor infant who was completely salivated by taking them, whether only from the calomel which they contain, or from this having become bichloride of mercury, I cannot say. As I believe a vast amount of mischief is done with such powders, used as they are indiscriminately, I never allow them to be sold without informing the purchaser that they contain calomel, and that their use is attended with danger.

B.

[*** We learn that the fact mentioned by Dr. Polk, as to the presence of perchloride of mercury in saccharated calomel which had been prepared a month previously, has been recently confirmed at the request of Dr. De Vrij by one of his former students, Mr. A. C. Cramer, at present superintendent of the pharmacy of the town of Rotterdam. This gentleman in examining a mixture of calomel with sugar of milk, which had been prepared at the same time as the saccharated calomel and in the same proportions, found that it also contained perchloride of mercury, although in a much smaller amount than the saccharated calomel. The total absence of perchloride of mercury in the calomel used for these experiments had been previously carefully ascertained. Mr. Cramer intends to continue his inquiry quantitatively under different circumstances, and to publish his results in this Journal.—Ed. Ph. J.]

Discovery of Cryptopia.

Sir,—In the valuable 'Year-Book of Pharmacy' just issued we observe an error with respect to the merit of the discovery of cryptopia. Mr. H. Ludwig, in his 'Review of the Alkaloids of the Papaveraccæ,' ascribes the discovery alike to Mr. J. Smiles and ourselves. On the contrary, the discovery is ours exclusively.

Mr. Smiles's connection with the matter is confined to having observed and drawn our attention to an unusual condition of certain mother-liquors which we were led to investigate, and our researches resulted in the discovery of cryptopia.

These facts are already published in our paper, which appeared in the *Pharmaceutical Journal*, new series, vol. viii, 1867.

A similar error to that now corrected appeared in Bouchardat's 'Annuaire de Thérapeutique' for 1873, but this publication has spontaneously, in last year's issue, correctly ascribed the discovery to us alone.

ON THE IDENTITY OF GOA POWDER AND ARAROBA.*

BY E. M. HOLMES.

During the past few months Goa powder has attracted considerable attention in medical journals as a specific for certain cutaneous diseases, and its identity with araroba, a drug lately imported into this country, has lately been suggested by Dr. Lima, of Bahia. With a view of ascertaining whether they are identical I have endeavoured to trace the araroba to its commercial and botanical sources, and have made a few simple experiments upon both drugs with various reagents.

About a year ago eight casks of araroba were imported into London from Bahia, but did not command a ready sale, as nothing was then known about its properties. It was, however, finally disposed of and disappeared. Some months afterwards the same drug appeared in the Liverpool market, and I am informed that it was imported there direct from Bahia.

The drug as imported consisted partly of lumps of a yellowish substance, some of which was in the state of powder, and partly of fragments of a yellowish wood. The lumps were not all yellow, some had a pink colour when broken, and some were almost entirely made up of grains or layers of a dark red or brown substance. On slicing some of the fragments of wood contained in the araroba, the powder was found to occupy insterstices in the wood in which it must have been deposited during the growth of the tree. As some of the lumps are of considerable size, it appears probable that portions of the woody fibres decay in the heart of the tree, leaving the araroba deposited in the cavities thus formed.

The microscopical structure of the fragments of wood found in it appeared to me to be very similar to that of *Cæsalpinia echinata*, with which I compared it, and partly on this account and partly because Martius in his 'Materia Medica of Brazil,' mentions the name as being applied to a species of *Cæsalpinia*, I concluded that it was probably the heart wood of a species of that genus.

While endeavouring to ascertain to what species of *Cæsalpinia* the name araroba was applied in Bahia, Professor Oliver pointed out to me that there was a note upon araroba in Martius's 'Flora Brasiliensis.'† In that work it is mentioned as the vernacular name for two species of *Centrolobium*; the two species are *Centrolobium robustum*, which yields the well-known zebra wood, and *C. tomentosum*. Of the wood of the latter he gives no description, but his account of zebra wood is interesting and, if araroba be derived from that tree, would account in some measure for the variation in colour seen in the lumps of araroba. The following is an abridged translation of it.

"In primeval forests it is a tall tree with a very thick trunk, the wood of which varies wonderfully in the hardness, thickness, and colour of the fibre, according to the circumstances attending its growth. An old trunk cut vertically shows at the same time many colours, in layers of different thickness, and without any distinct lines of separation. The inner layers are not always the darkest, but the light and dark hues alternate in various ways. In younger trees the colour of the wood is more frequently of a red tint or tinged with rose, hence the name, which means red wood. This colour is not permanent, but turns to a brown, or deep red, when exposed to the air, so that tablets cut out of the wood in course of time usually show dark bands or spots, on which account it has received the name of zebra wood. The wood does not, however, always show these red and ultimately darkened layers, but is sometimes found of a pale yellow or flesh colour, especially in sandy districts and in open sunny places."

The above description of the wood seems to correspond with the characters mentioned as belonging to araroba, and to indicate that that drug is obtained from the tree which bears its name.

Dr. Bomfim, professor of botany at Bahia, states,* however, that the name araroba or arariba is applied to a number of trees by the natives, and that the trees to which the name of araroba is applied by Martius do not yield that drug. The tree which yields it he believes to be one as yet undescribed by botanists. He has, however, only seen the leaves and a portion of the wood. The botanical source of the drug, therefore, seems to be at present unknown. Lately, however, Dr. J. L. Paterson, of Edinburgh, has brought home and deposited in the Royal Botanical Gardens, at Edinburgh, two cuttings of the plant. We may therefore hope, ere long, to have some definite information upon this point.†

With regard to the identity of this drug with Goa powder, the evidence given by Dr. Lima in the *Medical Times and Gazette* evidently points to their geographical source being probably identical, as their physiological action certainly is. One difficulty, however, still remains, and that is the very different colour of Goa powder and araroba. With a view of solving this difficulty I examined the specimen presented to the Pharmaceutical Society eleven years ago by Mr. Kemp. I found it to be of a chocolate brown colour, as then described.‡ Dr. Frazer, however, speaks of it in the year 1874 as a fine yellowish powder; a specimen lately presented to the museum by Mr. Postans, and which came from Treacher and Co., of Bombay, is of a dull ochre, or pale brown colour, and another specimen which I have received is of an umber-brown. The difference in colour cannot therefore be any objection to the identity of araroba with Goa powder. Since Professor Attfield had discovered that araroba, or chrysarobine as it has been lately named, contained a large percentage of chrysophanic acid, it occurred to me that a rough but ready test of identity would be to ascertain if this body were present in Goa powder. I therefore digested separately a few grains of each specimen in liquid ammonia, alcohol, ether, benzol, chloroform and strong sulphuric acid, in all of which chrysophanic acid is said to be soluble. In all the specimens the colours of the solutions were similar with the respective solvents; thus the ammonia gave a deep reddish purple solution, and chloroform and benzol deep-brown solutions, both in the araroba and in all the specimens of Goa powder. I therefore think that a more accurate and careful examination by those who have the time and opportunity will

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, on Wednesday, April 7, 1875.

† Papilionaceæ, vol. xv., part 1, p. 264.

* *Medical Times and Gazette*, March 6, 1875, p. 250.

† Since this paper was written, I have received, through the courtesy of Mr. J. Sadler, a leaf from one of these slips, and I am thus enabled to say that the leaf is not that of a *Centrolobium*, but appears to be that of a species of *Cæsalpinia*, nearly allied to *C. Sappan*.

‡ *Pharmaceutical Journal* [2], vol. v, p. 345. This colour does not appear to have become darker since it was deposited in the museum, and any change which has taken place must have occurred before that date.

prove that these two drugs are absolutely identical. I would also suggest that the substance to which they owe their physiological action is worthy of trial in the pure state. It is a principle widely distributed in nature, being known to occur also in three species of rhubarb, several species of dock, in senna, and in the common yellow lichen, *Parmelia parietina*. It is worthy of note, also, that in the time of Gerarde, dock-root was used in the form of ointment and decoction, as an external application for various skin diseases, and is still so used by herbalists in country districts, and I have been informed, with considerable success. With regard to the best method of applying araroba and Goa powder, I have been favoured with the following information by Mr. Postans. When applied as in India by making it into a cream with lemon-juice, vinegar, or water, it strongly discolours the skin, and even the hair, and is apt to cause considerable swelling and inflammation. This method of using it has also the disadvantage of allowing the powder to become scattered about as soon as the vinegar, etc., is dried up. In one case which came under his notice the Goa powder having been applied to the head, some of the powder found its way into the eyes and caused dangerous inflammation. He therefore recommends it to be made into a paste with juniper tar oil, olive oil, or lard. In Bombay it is commonly sold as a tincture and as an ointment. The cost of the drug obtained from Bombay was £3 12*s*. per lb.

I may add that I mixed some alcoholic tincture of Goa powder with glycerine and applied it to the back of my hand, but did not find that it left any stain.

[*The discussion on this paper is printed at p.* 816].

NOTES ON THE PHARMACY OF ATROPINE.*

BY W. WILLMOTT.

So largely is the therapeutic or surgical value of atropine dependent on the care devoted to its preparation, that, as a remedy requiring absolute purity, it has called for closer attention on my part than otherwise I should have considered needful. Indeed, I may say that, as Dispenser to one of the large London Hospitals, I have been specially appealed to on the subject. If these "Notes" should appear to partake to some slight extent of a medical character, I can only plead that it is no pretension on my part, but simply a necessity in carrying out an inquiry which is strictly pharmaceutical in its object and result.

I need scarcely say that atropine, or atropia, is obtained from the root of the Atropa belladonna by a rather complicated process. Briefly, however, it amounts to this:—A strong spirit tincture is prepared from the root, lime is then added, and afterwards diluted sulphuric acid in slight excess. This is followed by the addition of potash after evaporation of the spirit, and the atropia thus set free is dissolved out by chloroform, decolourized with animal charcoal, and finally crystallized from an alcoholic solution. This process will be recognized as that of the British Pharmacopœia, which, in fact, is simply a modification of Mein's improved method,—*i.e.*, improved as compared with that originally devised by Brandes, the discoverer of atropine, in 1819. The objection to Brandes' process lay in the employment of caustic potash, which, being heated with atropia, was found to decompose it evolving ammonia. In December, 1854, a paper was read at a meeting of this Society by Mr. W. T. Luxton, M.R.C.S., on "An Easy Method of Preparing Atropine," in which the author suggested the substitution of ammonia for potash in precipitating the alkaloid. The suggestion, however, was not sufficiently practicable, and consequently failed to receive support.

Atropine had been for some years in use in Germany, great advances having been made in the study of its preparation and medicinal effect; but it was not until the year 1844 that it received the attention of ophthalmic surgeons in this country. At that date, Mr. White Cooper drew attention to atropine as a new and superior agent in place of belladonna (chiefly the extract) then in use. This was followed by a communication from Mr. J. Lloyd Bullock, suggesting that inasmuch as Mr. Cooper's solution involved the use of spirit of wine, thus constituting a *primâ facie* objection, the *salts* of atropine, which were neutral and soluble in distilled water, should receive a trial as being in all probability preferable to the dissolved alkaloid both in use and effect. This suggestion was accepted unreservedly. The sulphate, which is very soluble without extraneous aid, is now almost universally employed, where applicable, in varying strengths, from 1 to 4 grains to the fluid ounce.

I cannot pass from these introductory remarks without reference to certain information for which I am indebted to the kindness of Mr. Williams, who, in a conversation on the subject entered fully into the merits of the question, giving me also the results of his extensive experience of this important substance. "The Germans say of us," remarked Mr. Williams, "that we make belladonnin and not atropine, and we say the same of them. There is," he continued, "no doubt of there being an atropine in the market containing an acridity which gives rise to pain. That atropine should cause pain when applied to the eye is not a new thing; it frequently does so. Medical men say that some atropines give rise to pain and irritation, whilst in the same cases other atropines are well borne. In practice, the process of the Pharmacopœia is rarely, if ever, strictly adhered to. Atropine requires great care in preparation, or it would, no doubt, contain free sulphuric acid. Different makers produce different results as to the quality. No impurity would be found in atropine if properly prepared. There are only the two alkaloids, atropine and belladonnin." These are valuable hints, and have direct reference to the facts herein duly set forth.

It has been stated of atropine that it frequently causes pain when applied to the eye in the familiar form of "drops." Our main inquiry, therefore, will be,—To what is this due? For, truth to say, important as the question may be, it is not definitely known how or in what manner this peculiarity is brought about.* It is for this reason that I find myself engaged in an inquiry which is certainly new to the pharmacist, but which has been urged upon me by the consideration that at his door the blame may be laid, and that therefore he is bound in all doubtful cases to demonstrate as far as possible the integrity of the substances produced by chemical aid for the prescriber's use.

In ophthalmic practice atropine is used to dilate

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, on Wednesday, April 7, 1875.

* Some few instances have been traced to idiosyncrasy or intolerance of the remedy in any form; but other instances more frequently occur to which this explanation clearly does not apply.

the pupil for purposes of diagnosis, and for the prevention or removal of adhesions. It is also said to be sedative in its action; and for these and other reasons we find it freely prescribed. Now, it will be readily understood that as most hospitals and infirmaries have a special department for the treatment of diseases of the eye, in that department atropia is an all-important substance; and when we remember that it is the organ of vision with which we are dealing, the force and truth of this proposition can hardly be overstated; so that clearly nothing short of an absolutely pure sulphate should be used in all the collyria, discs, or drops prescribed to contain it.

It was about three years ago, at King's College Hospital, that the cases became frequent in which pain and irritation were set up by the use of the ordinary liquor atropiæ sulphatis of the British Pharmacopœia. I was not only called to the consulting room to observe these cases, but the surgeon was good enough, at my request, personally to visit our department and himself examine the solution we were then using. As no explanation was at all apparent, I commenced taking notes with a view to discover how far this unusual frequency of a distinctive peculiarity was due to the atropine—perhaps on these occasions too readily accepted as the cause.

I had been informed that at the hospital in Moorfields such cases as I have described were unknown, and accordingly I hastened thither to learn the secret of this success. My surprise was indeed great when I found that a committee had been appointed for the following week to consider the question of the atropine in use there, the quality of which had not been found satisfactory. In the reports of this hospital (vi., 119) attention is called by Mr. George Lawson to the precise effects here referred to, showing clearly that they are not confined to one institution; and although he believes that when the sulphate acts thus as an irritant it is due to some idiosyncrasy on the part of the patient, yet amongst medical men generally the alkaloid itself is not held acquitted of blame. Three suggestions have been offered as possible sources of the mischief residing in the atropine, viz.: 1. Impurity; 2. Acidity; 3. Change of condition by long keeping; and to each of these I will now briefly direct attention.

1. *Impurity.*

In suspecting impurity as a source of mischief in atropine, we are reminded that the specific action of any given remedy is an all-important consideration. We inquire, therefore, of the ophthalmologist if we ought to expect pain from the use of atropine, as we do, for instance, from the application of nitrate of silver, and he replies,—"No, there should be almost immediate dilatation of the pupil, but no pain." What more natural, then, in these exceptional cases, than to fix upon impurity as the cause? But here the question arises,—Given an impure atropine, and what is the probable impurity therein contained? To this apparently simple question I found it no easy matter to obtain an answer, whilst my efforts to meet with an impure atropine for purposes of comparison failed in every way.* In truth, so far as my experience extends there is no such substance to be procured, and I am inclined to look upon such a possibility in the ordinary course of dealing with chemists of repute as very questionable, though Mr. Williams, as we have seen, has hinted differently. I have used atropines from many, if not all sources, and have found all the specimens equally pure and good.* During my use of even the cheapest that could be obtained, no complaint reached me of any ill effect from its application in the ordinary way. Nevertheless, surgeons adhere to the hypothesis that when irritative action is set up it probably arises from some impurity or change in the solution used. Hence, in our own case, we are not unfrequently confronted with memoranda from the prescriber to the following effect:—

"Please to see that the drops are pure, as some patients complain of their hurting."

"The drops hurt. Query impure."

"Drops to be very pure."

Whenever an intimation of this kind comes under my notice I invariably address myself to the patient with the foregone conclusion that upon him or her the solution of the problem will be found to rest. On this head the following case will be instructive:—

"*J. D. Aged* 27. *Dimness of sight.*

"Jan. 8. Ordered atropine drops; strength two grains to the fluid ounce.

"Jan. 11. Repeat drops ("purissima")—

"Memorandum on letter [prescription]. 'The last drops irritated considerably.'

"NOTE.—Patient is a plumber by trade, and states that the vapour from the hot grease employed in his work will of itself cause smarting and pain in the eye. Uses a camel hair pencil for dropping the solution—the 'same that he used last summer when attending Charing Cross Hospital for a similar complaint.' Keeps the bottle containing the drops on kitchen shelf."

Here I think it will be admitted that we have sufficient cause for the irritation, without blaming the remedy prescribed. This is but one example of many such cases that might be given; and it is more than probable that in the majority of instances of an approximative character, careful investigation would show similar results.†

"*C. G. Aged* 22. *Cataract.*

"April 4. ℞. Atrop. Sulph. PUR. gr. iv.

"Aq. ℥i.

"Ft. Guttæ. 'Please see that they are VERY pure.'

"'To be admitted on Sunday evening.'

"April 9th. Patient admitted. Reordered drops.

"No complaint of the atropine given on the 4th. May 2nd. No complaint."

Here, then, we have a case where great purity was required, and in which the *German* sulphate (the kind dispensed) was found to be completely satisfactory.‡

* The B. P. test—"leaves no ash when burnt with free access of air,"—points to mineral matter as the chief impurity to be looked for in this alkaloid.

* "Impure atropia is not crystalline, is more or less coloured, and has an unpleasant odour."—*Pereira's Elements*, 1872. "Atropia.—The characteristic odour is best developed by placing the alkaloid upon a few crystals of CrO_3, and applying gentle heat until green Cr_2O_3 begins to form."—*Year-Book of Pharmacy*, 1874.

† As atropine drops are seldom properly used by patients, and certainly, in their hands, very carelessly kept, it is perhaps to be regretted that this remedy cannot be applied by the practitioner himself, in the consulting room or surgery of the hospital.

‡ I believe I am correct in stating that, on account of the heavy duty levied on rectified spirit, the great bulk of the atropine used in this country is imported from Germany, and converted into sulphate by manufacturing chemists, as occasion may require. I have reason to believe that very little of the alkaloid is really manufactured in the metropolitan laboratories.

"*M. L. Aged* 50. *Iritis.*

"March 7. Ordered atropine drops, 4 grains to the ounce.

"March 11. Repeat. Memorandum on letter: 'Please see as to the drops; the last hurt the eyes.'

"NOTE.—Drops neutral and bright. The smarting soon subsides, and patient does not think the eye is worse in consequence. To come again on Monday.

"18th. Eye improving. Drops still hurt, but not so much. Doctor says the smarting will get less as the eye gets better.

"25th. Patient reports that there is now no pain or smarting in applying the drops. Repeat. No further complaint."

The atropine used in this case was obtained from one of the most eminent chemists' firms in London, whose name is a sufficient guarantee for the unexceptionable purity of all their preparations. We have, therefore, in this instance, an illustration of the circumstance that what was unquestionably pure atropine will sometimes produce pain and smarting, thus rendering an appreciation of the real cause in any given case a matter, it may be, of some difficulty even to the most experienced practitioner.*

2. *Acidity.*

We now come to the question of acidity, and herein is another supposed explanation of the peculiarity under consideration. "A more serious difficulty arises," says Mr. Brudenell Carter in "Contributions to Ophthalmic Therapeutics" (*Practitioner*, July, 1869, p. 27), "when the atropine acts as a local irritant. It does so in some degree not very unfrequently, where its use has been long continued; and the explanation is, I believe, that the solution when given into the custody of patients often loses its neutrality, or undergoes other changes, from keeping, and from exposure to sunlight." The observation that the solution often loses its neutrality when given into the custody of patients is perfectly true, but that this is an explanation of the "serious difficulty" referred to does not accord with the result of my inquiries so far as I have been able to carry them. I find that much of the solution sent out from the hospital in a perfectly neutral condition is returned a week afterwards distinctly acid to test-paper, whilst the remaining portion of the same solution retains its neutrality as completely as when first supplied to the patient. I frankly confess that this little mystery I have never been able satisfactorily to solve. I have tried by every fair means to produce this acidity, but have always failed. A solution of 4 grains to the ounce has been evaporated very slowly in the sunlight for weeks; then redissolved and again evaporated; again dissolved and again exposed as before, and yet no trace of acidity could be discovered when tested with litmus. A cork has been cut into pieces and shaken with the atropine occasionally for months with exposure to air and light, and still no distinctive reaction has been shown. Doubtless, by and by, I shall be on the right track of discovery, but in the meanwhile it is unimportant, since the presence of this acid in the solution is really not the cause of any irritative effect it may possess. To test this I ventured, in a given number of instances, to add free acid to a point which gave a distinct reaction on blue litmus. It was a bold experiment, I admit, and I awaited the result with some anxiety, and with many forebodings of the numberless complaints to be encountered. But to my great astonishment, not a single memorandum reached me in any one instance. Selecting those cases where atropine had been previously used without complaint I carefully made my notes, and on reference to them at this date find them run as follows:—

"*E. H. Aged* 28.

"Jan. 29th.—Has been using atropine since the 1st. Attends every Monday. Solution neutral. Repeat and acidify with the $\frac{1}{25}$th of a drop of acid. sulph. dil. to each fluid drachm of the solution.

"Feb. 5th.—No complaint. Repeat drops *sine* acid."

"*J. R. Aged* 40. *Iritis.*

"Jan. 31st.—Has been using atropine since the 20th. Solution neutral. Repeat and add to each fluid drachm gtt. $\frac{1}{25}$ acid. sulph. dil.

"Feb. 5th.—No complaint. Repeat drops *sine* acid."

"*M. A. S. Aged* 48.

"Jan. 29th.—Has been using atropine since June 15th, 1871. Attends once a fortnight. Give drops made strongly acid to test-paper.

"Feb. 12th.—No complaint; no smarting. Repeat drops omitting the acid."

And so on throughout the whole number selected for trial. Similar results present themselves where the acid is not added but is engendered, as I have hinted, from some unknown or unexplained cause.

"*J. K. Double cataract.*

"May 4th.—Ordered liq. atropiæ sulph., P.B. (Neutral when given to patient).

"May 15th.—Drops strongly acid. No complaint of smarting. Patient going on well. Repeat, taking care to give neutral solution.

"May 29th.—Drops again very acid, but no irritation or pain from their use. Mother of the patient states that she lives over stables, and keeps the drops on a shelf over a water-tank. Uses a fresh quill twice a week, and places it in hot water before using. To keep the drops in another place.

"June 12th.—The same acid condition of the solution is again apparent, but still no complaint of smarting or pain. Finds no difference in effect when the drops are first used as received from the hospital, and when they are last used. The acidity does not affect the eye prejudicially, or cause smarting in any degree."

To the foregoing I will add, by way of support to my "Notes," the following authoritative testimony. The *Lancet*, May 2nd, 1868, commenting on the hospital reports already referred to, says:—"The irritative effects occasionally witnessed from the use of a solution of sulphate of atropia have been generally ascribed to the presence of some free acid in the solution, but Mr. Lawson doubts the truth of this explanation and very fairly points out that salts containing much more free acid, as, *e. g.*, the sulphates of zinc and alumina, are used daily in ophthalmic practice without irritant effect." Thus it is clear that inasmuch as this peculiar change in the solution, viz., acidity, under the patient's own keeping is of constant and continuous occurrence, the inference that it is the cause of the mischief complained of in a certain few cases receives no support from those prominent facts which investigation so clearly reveals.

3. *Change of condition by long keeping.*

Little need be said to show that a solution of pure sulphate of atropia will keep for an indefinite period without change. Some in my possession prepared nearly five years ago is now quite good in every

* "In some individuals, even in weak doses, atropine excites irritation."—*Med. Times and Gazette*, April 25, 1868.

respect; and I have in three separate bottles solutions of different atropines showing no change, though prepared so long ago as the 24th of February, 1872.

The following case, will, I think, be sufficiently conclusive on this point:—

"*J. P.* (*Iritis*).

"April 17th. Atropine drops previously used repeated. Memorandum from surgeon:—'These drops smart again.'

"April 24th. Repeat drops. Memorandum from surgeon:—'Guttæ Atropiæ same as last, which did *not* smart.'"

I have only to say that here the solution which gave rise to the smarting was freshly prepared, whilst that which "did *not* smart" was taken from a small quantity which had been set aside many months previously on account of its terrible delinquency, or supposed delinquency, on several important occasions. This latter solution was subsequently used again and again with the usual specific effect. I think, therefore, that we must seek for another cause to account for the occurrence of the peculiar phenomenon in question; always reserving those instances where intolerance of the remedy, or idiosyncrasy, is the acknowledged and unquestioned explanation. What, then, is the probable source of this mischief? I have no hesitation in expressing an opinion that in the majority of instances it arises from the presence of particles of solid matter (dust and dirt) which find their way into the solution, and from thence into the eye itself. We all know the disastrous effect of dust when brought into contact with the eye even in a state of health. How much more likely, then, to cause pain and inconvenience when that delicate structure is disorganized to however small an extent.* Amongst my "Notes" I have two or three illustrations of this, and they will be the last I shall need to give.

"*E. S.*, *aged* 14. (*In patient*).

"June 26th. Eye drops sent down from the Ward with the following memorandum written on prescription:—'To be exchanged for atropine that does not irritate.'

"NOTE.—Examined solution and found it neutral, but full of dust. Passed it through filtering paper and returned it to the ward.

"July 5th. Bottle sent down for further supply of atropine. Solution neutral. No complaint. Nurse reports no irritation, and all well."

"March 13th. Memorandum received from the resident accoucheur:—'The child B. having complained of great smarting in the eye after the introduction of the atropine, the solution is considered impure. A fresh one should be made.'

"NOTE.—Examined solution and found it charged with particles of dust, but unexceptionable in all other respects. Passed it through filtering paper and returned it to the ward, with instructions that a new and clean quill should be used.

"March 18th. Resident accoucheur reports that the child has not since complained of pain. Previously the drops caused much smarting and irritation.

Here, then, we are presented with facts which seem clearly to bear out the explanation I have ventured to suggest. I do not say, nor does my paper purpose to show or prove, that dust and dirt are *necessarily* at fault in every case of irritation which may occur through the use of atropine; but certainly my first care would be, under such circumstances, to examine the solution, with a view to the detection of the presence of any of these irritative agents.* That impurity, acidity, or an acrid condition of the alkaloid may each and all produce mischievous effects on the eye (though my experience furnishes no *proof* of such) can scarcely be doubted.† It concerns us intimately, therefore, in dispensing this remedy, to see that these undesirable accompaniments are not present therein. And when we add to the possibility of mischief arising from its use, the undoubted fact that atropia has a special importance in ophthalmic surgery, and at the same time bear in mind the anxious and possibly disastrous character of any affection which may attack the organ of sight, we shall consider no attention too great that can be bestowed upon the preparation and storage of this highly organized substance, the absolute integrity of which, as, in the case unreservedly of all our medicaments, it is incumbent upon us, not only faithfully to advocate, but strictly to observe and maintain.

[*The discussion on this paper is printed at p.* 818].

* "The intrusion of foreign matters may excite other effects than those of mere inflammation . . . . a detached eye-lash between the lids gives rise to much irritation, and sometimes a most obstinate chronic ophthalmia is found to depend entirely on a minute light-coloured one becoming inverted." —*Practical Treatise on Ophthalmic Medicine.* By E. O. Hocken, M.D. 1844.

* The insidious character of dust, as strikingly shown by Professor Tyndall in his well-known lecture on "Dust and Disease," is unquestionable. It may find an intrusion at any time, and will often elude the most careful vigilance.

† Mr. Wells, in his valuable 'Treatise on Diseases of the Eye' (foot-note, p. 100), refers to instances in which pure solution of atropia has produced great irritation and pain, but says:—"This is, however, a very exceptional occurrence, and bears not the least analogy to those cases in which the irritation is caused by the impurity of the atropine."

ERGOT AND ITS LIQUID EXTRACT.‡

BY A. W. GERRARD,

Teacher of Pharmacy at University College Hospital.

In bringing this subject forward, the prime objects I have in view are to point out some defects in the official process for preparing the liquid extract of ergot, and to give a method for making it which my experience has taught me will yield a superior preparation.

I will preface my remarks with a brief statement of our present knowledge as to the chemical properties and composition of ergot itself, for I consider this knowledge places one in a better position to judge or decide upon the treatment the drug should undergo for a proper extraction of its active constituents.

Standard works of chemistry and materia medica afford but brief information concerning this drug. Flückiger and Hanbury, however, in their 'Pharmacographia' have brought in coalition the researches of various investigators upon it up to the present time; this excellent work, therefore, contains the fullest information with reference to ergot of any book with which I am acquainted. Following are some of the more important extracts therefrom.

"According to Wenzell, ergot of rye contains two alkaloids combined with ergotic acid, soluble in water, which he designates ecboline and ergotine; ecboline possesses in a high degree the special medicinal properties of ergot; ergotine has, however, but little action; ergot also contains a sugar termed mycose, lactic acid, albumen, and red colouring matter.

"According to Wiggers this drug contains 30 per

‡ Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, on Wednesday, April 7, 1875.

cent. of saponifiable oil, with small portions of acetic and butyric acids combined with glycerine; the oil is also accompanied by small quantities of cholesterin and resin."

Flückiger and Hanbury state that the crystals which abound in the kept extract are acid phosphate of soda and ammonia, with a small portion of sulphate; my investigation of these crystals proves them to be acid phosphate of potash, with a trace of ammonia.

When to ergot or its liquid extract a caustic alkali is added and a gentle heat applied, a mixed ammoniacal odour is evolved characteristic of trimethylamine, which ammoniacal base it is pronounced to be; this effect is probably due to decomposition of albumen, of which ergot contains a considerable quantity.

It is thus seen that in ergot of rye we have a substance to deal with of a naturally delicate and chemically intricate character, rapidly undergoing change and losing its activity on exposure to atmospheric influences; its proper preservation is therefore a matter of paramount importance, dryness and close packing I have found most essential to this end. On the receipt of a parcel, which should be as fresh as possible, let it be examined as to its dryness, and if dry bottled immediately, fixing a piece of lime, tied in muslin, to the interior of the stopper. By adopting this expedient I have found the ergot at the expiration of a year to yield an extract equally active as that prepared from the fresh sample.

I will now ask attention to some remarks upon the liquid extract of ergot of the British Pharmacopœia.

It is made by removing the oil from one pound of ergot by one pint of ether, or a sufficiency, macerating it in 3 pints of water for twelve hours at a temperature of 160° F., then pressing and straining, and evaporating to 9 fluid ounces; when cold add 8 fluid ounces of rectified spirit, set aside to coagulate albumen, then filter. The product should measure 16 fluid ounces.

I will now report upon each division of this process step by step, and introduce suggestions which I have found to be improvements.

Removal of the oil by ether has been pointed out by Umney and others as a wasteful and unnecessary proceeding. My experience agrees with them, for it has been found that the resultant extracts prepared with or without ether extraction differ not in their therapeutic effects, neither as pharmaceutical preparations.

The second step in the process is maceration of the ergot in 3 pints of water for twelve hours, at a temperature of 160° F. I find after the ergot has been in contact with the water at this temperature for a few hours it swells, and the mass assumes a semi-colloid condition, so that pressure and straining, the next part of the process, is absolutely impracticable.

These difficulties suggested to me the use of cold water as a solvent, and I find it perfectly successful, using 6 instead of 3 pints, and proceeding thus: macerate the ergot in 4 pints of cold distilled water for twenty-four hours, then transfer to a muslin strainer, when the fluid ceases to pass pour upon the ergot the remaining 2 pints of water, allow this to pass, then press the marc. By this method a more thorough exhaustion of the ergot is ensured than by the B.P. process, and the annoying property of partial gelatinization avoided.

During the summer months, at the temperature of 160°F., the mass speedily undergoes fermentation. If this takes place the resultant extract is very acid and has an unpleasant odour. This objectionable property I consider to be an additional argument in favour of cold extraction.

The next and last step in the process is the evaporation of the strained fluid to 9 fluid ounces, allowing it to cool, then adding 8 fluid ounces of rectified spirit and set aside to allow albumen to coagulate, then filter. The product, we are officially informed, should measure 16 fluid ounces: my experience proves that it does not measure this amount. Upon adding the 8 ozs. of rectified spirit to the 9 ozs. of extractive, condensation of volume takes place, it measuring 16½ ozs., being less by half an ounce than the original bulk. The albumen has now to be separated officially by filtration, which I find cannot be done; decantation and straining through tow answers best. When this is performed the ultimate product measures 14½ instead of 16 fluid ounces. This result was almost invariable on several occasions.

My process then, of which the preceding remarks contain the details, consists simply of macerating 1 pound of ergot in 4 pints of distilled water for twenty-four hours, transferring to a muslin strainer, adding 2 pints more of water, allowing this to pass, then pressing the marc, evaporate the fluid to 10 ozs., then add 8 ozs. of rectified spirit, and when the albumen has coagulated, decant the clear portion and strain the remainder through tow. The product should be made to measure 16 fluid ounces.

A specimen of extract prepared by this process I have placed upon the table. There is also a bottle containing the crystalline separation of the acid phosphate of potassium which occurred in four days. The extract has a sp. gr. of 1·013, and is a preparation which I feel confident must be acknowledged superior to that of the B. P.

A point in the preparation to which I am desirous of referring is the large quantity of spirit it contains; this I consider unnecessary and even detrimental to the product, for the following reason, it causes the separation and crystallization of large quantities of phosphates, especially when made by the process I have described. Whether these phosphates are an item of its activity I am unable to state, but I am inclined to consider them as such.

According to Wenzell, to whose investigations I have previously referred, the substance to which ergot owes its principal activity, viz., ecboline, is soluble in water; this, therefore, is an additional reason for reducing the quantity of spirit. I will recommend, therefore, the addition of one-fourth instead of one half its volume of rectified spirit; thus prepared it maintains its therapeutic effects equally with the other.

From a consideration of the continental and trans-atlantic formulæ I am of opinion that our British liquid extract maintains a superiority; that this may at some future period be replaced by a better is a reasonable desire. I have been lately engaged in the preparation of an ammoniated extract, the addition of ammonia being said to give ergot increased activity. Results that have been obtained from its use are promising; further therapeutic data are, however, required; when these are forthcoming I trust to be able to give you a report upon it.

These remarks principally consist of my own experience in the pharmacy of ergot; it is a drug to which we cannot devote too much care and attention, for it is often the thread upon whose strength the life of mother and offspring depends.

[*The discussion on this paper is printed at p.* 819].

The Pharmaceutical Journal.

SATURDAY, APRIL 10, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

EXAMINATION FALLACIES.

THE establishment of an examination test as a necessary preliminary to entering upon the business of a chemist and druggist is so recent in this country that it is not surprising to find a certain vague feeling of discontent manifesting itself among some of those who have to undergo the ordeal of examination. If, however, the nature of the examination be considered, it will be found that, in almost all cases, such a feeling can only be regarded as indicative of deficiency in the acquirements which are universally recognized as being indispensable not only for all who carry on the business of the pharmacist in its higher branches, but, likewise, even for those who deal in drugs. Of such a nature are the complaints that from time to time appear as to the hardships occasioned by having to pass an examination. The recent alterations that have been adopted in the examinations have afforded an opportunity for putting forward the grievances that have been supposed to exist in regard to this matter. But, however much we may, in a general way, sympathize with those individuals who, after having spent some years in the business as apprentices or assistants, nevertheless find themselves unable to cope successfully with the examination that is the test of their fitness for commencing business on their own account, we cannot call to mind anything that has been adduced which tends in the least either to shake confidence in the propriety of an examination test, or to disturb the conviction that those who cannot satisfy the requirements of this test should be precluded from carrying on the business of the pharmacist.

The practice of all other countries is either in conformity with the view that has been stated or is in course of adapting itself to the same principle. Moreover the system is not only desirable as regards the interests and safety of the public, but it is also desirable from the pharmacist's point of view that properly qualified men should not be exposed to competition with persons who are wanting in the scientific knowledge and practical skill essential to the calling. However this matter be regarded, therefore, it would seem to be the first duty of those who have the interest of pharmacy at heart to uphold the examination system and jealously to maintain a high standard of qualification.

We have been led to mention this subject by a most remarkable incident that has taken place at the late Council meeting. We refer to the presentation of a memorial addressed to the Council of the Society by the Pharmaceutical Chemists and Chemists and Druggists of Glasgow and the West of Scotland. This memorial is printed in full at page 814, and therefore we need only mention here that the memorialists state they are firmly of opinion that some of the regulations laid down for conducting the examinations of the Pharmaceutical Society are inimical to the future progress of pharmacy in their part of the kingdom, and that these regulations have done much to estrange young men from becoming apprentices or students of the business.

Exception is also taken in this memorial to the mode of appointing Examiners, especially in Scotland, as having been unfair to the great body of qualified pharmaceutical chemists throughout the country, and detrimental in some respects to the interests of candidates for examination.

These allegations are of so grave a nature that it is remarkable they are not supported by some statement of facts illustrative of the supposed defects and evils which have led to the presentation of this memorial. This, however, is wanting, and even Mr. FRAZER, who at the Council meeting expressed himself as being prepared to support the memorial, confined himself to stating as his reason for doing so that in the West of Scotland there is a great difficulty in obtaining assistants. It was to this circumstance also that he mainly attributed the existence of a strong feeling on the subject of examinations in that part of Scotland.

Certainly it seems a somewhat remarkable fact, considering the gravity of the subject dealt with in this memorial and the strong feeling Mr. FRAZER believes there is respecting it, that no more than seven or eight persons should have been induced to attend the meeting at which the memorial was adopted and directed to be sent to the Council of the Pharmaceutical Society. Still more remarkable is it, considering the existence of a Branch of the Pharmaceutical Society in Scotland and in such immediate proximity to Glasgow, that action should have been taken independently by the Council of the Glasgow Chemists and Druggists' Association. The speech of Mr. MACKAY after the presentation of the memorial seems to point to the absence of any ground for such reticence, especially in regard to the complaint as to the appointment of Examiners.

To enter upon any criticism of the measures proposed by the memorial as a remedy for the evils that are assumed to exist in the conduct of the examination would be superfluous until there were some tangible evidence that the alleged evils have any real existence, and until that is attempted nothing need be added to what was said by several members of Council. There is, however, one contingency suggested by Mr. MACKAY's remarks—we trust not a probable one—which it would be well to consider in connection with the Examiners and the important duty that has to be performed by them. We refer to the difficulty experienced in making up the Examination Board and the reluctance there is to give up the time and bestow the labour which are required in conducting the Society's examinations.

It may also be useful to the Pharmaceutical Chemists and Chemists and Druggists of the West of Scotland if an inquiry were made with the view of tracing to its true source the difficulty said to be experienced there in obtaining apprentices and assistants. We are disposed to believe that in this way it would be possible to disclose some more reasonable ground for disinclination to enter the business of pharmacy than the alleged defective nature of the examination test of fitness for that business. We have no doubt such an inquiry would serve to convince the authors of this memorial that they are labouring under very erroneous views, and that by the opinions they have expressed, they have contributed to the support of an unwholesome, though at present to some extent natural, aversion to the test of the examination room, thus in fact, acting inconsistently with the best interests of pharmacy which they claim to have at heart.

A PUBLIC ANALYST'S WARNING.

In a recent report, Dr. J. Campbell Brown, the Public Analyst for Liverpool, states that it has come to his knowledge, in a private manner, that some of the citric acid, tartaric acid, and other drugs consumed in that borough contain lead, not purposely added, but derived from the vessels in which the substances are prepared or stored. Dr. Brown states that being unable to give any official warning to dealers on the subject he has taken the opportunity of presenting this Report to make the fact known, in order that druggists and others who vend such substances may be on their guard and avoid the penalties to which under the Pharmacy Act they would be liable for the sale of such impure drugs.

INCORPORATION OF THE ROYAL VETERINARY COLLEGE.

We learn with pleasure that Her Majesty has been pleased to grant a Charter of Incorporation to the Royal Veterinary College. Among the powers bestowed by it upon the College is one of creating scholarships, and of awarding medals, prizes, and certificates to the students. To this is added the power of appointing former students to be "Licentiates," or those who have practised with particular distinction in their profession, "Fellows" of the College; also to bestow the higher honour of "Honorary Associate" on distinguished persons, native or foreign, who have contributed in an especial manner to elevate veterinary science.

In reference to the report in the *Pall Mall Gazette* and other papers of the trial of Alfred Thomas Heap, for murder, and describing him as a chemist, we have to state that no such appears on the Register.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, April 7, 1875.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Frazer, Greenish, Hampson, Mackay, Owen, Radley, Rimmington, Robbins, Sandford, Savage, Schacht, Shaw, and Williams.

The minutes of the previous meeting were read and confirmed.

The Late Mr. Daniel Hanbury.

The President said: Gentlemen,—Before commencing the business of the day, I feel it my duty to call your attention to the great loss Mr. and Mrs. Hanbury and family have sustained in the death of their eldest son, the late Daniel Hanbury, and I am sure that you will all join me in a letter of condolence and sympathy to them in their bereavement. It is not only the family of Hanbury that have sustained a great loss, but we also, and all connected with pharmacy and medicine, for Mr. Hanbury was not only a pharmacist but also a great authority on materia medica, as his work in connection with Professor Flückiger will testify. As I am sure that every one has read the interesting memoir published in the Society's Journal of April 3rd, I will not say more than ask your concurrence, together with that of the Board of Examiners, in a letter of condolence to Mr. Hanbury, our late much esteemed Member of Council and Treasurer, Mrs. Hanbury and family, on the great loss of their persevering, industrious, and talented son, the late Daniel Hanbury.

The Vice-President, in seconding the proposition, said: I feel with all of you that the loss of Mr. Daniel Hanbury is, indeed, not only a loss to us and to English society, but to European society; in truth, Mr. Hanbury's reputation was not confined even to Europe. We not only from time to time had great pleasure in meeting him, sitting under his influence, and receiving information from him, but we also rejoiced to see the position which one of our most highly educated members had attained.

Mr. Sandford, as an old member of the Council, could not allow the motion to pass quite in silence. He had known Mr. Hanbury as long as any gentleman in the room, and had seen very much of him in the early days of the Society, particularly when working with Mr. Bell in the conduct of the Journal, where his assistance was most valuable, and was highly appreciated by Mr. Bell. He also knew how Mr. Hanbury had worked in connection with the evening meetings and on the Board of Examiners; in fact, in every sense of the word Mr. Hanbury was an honour to the Society. He might, perhaps, be excused for a passing allusion also to the active part which Mr. Hanbury took in the institution of the British Pharmaceutical Conference, a most important off-shoot from the Society, and he felt that they could not do too much honour to the name of a gentleman to whom they were so deeply indebted.

Mr. Schacht said it was unnecessary to add a single word to what had been said, but his connection with the Pharmaceutical Conference might justify him in adding his small testimony to the general expression of the sense of the great loss which had been sustained. It was also a personal gratification to do so, inasmuch as he had been a fellow student with Mr. Hanbury in the first year of the School of Pharmacy. He would only say further that he had felt much pleasure in seeing the degree in which he had been surpassed by Mr. Hanbury, and especially in his attainment of the somewhat rare honour for a pharmacist of the title of F.R.S.

Mr. Williams, having known Mr. Hanbury for a very long period, had no hesitation in saying that they had now lost the most eminent man, not only in English but European pharmacy. The great work which Mr. Hanbury had happily lived to complete in conjunction with Professor Flückiger was his best and greatest memorial, and he believed he was justified in saying that it showed more of Mr. Hanbury's work than of his coadjutor's. A great deal of time and much of his private fortune had been expended in collecting materials for it, and he believed its publication would greatly tend to advance the science of pharmacy.

The resolution was carried unanimously.

Nominations for Council and Auditors.

The Secretary reported that there had been 23 nominations to fill the 14 vacant seats on the Council, and the following 17 nominees had signified their willingness to accept office if elected:—

Andrews, Frederick, 23, Leinster Terrace, Hyde Park, W
Atherton, John Henry, Long Row, Nottingham.
Baynes, James, 24, Waterworks Street, Hull.
Betty, Samuel Chapman, 6, Park Street, Camden Town, N.W.
Bottle, Alexander, 7, St. Martin's Terrace, Dover.
Brown, William Scott, 113, Market Street, Manchester.
Clark, Walter Beales, 15, Belvoir Street, Leicester.
Cracknell, Charles, 217, Edgware Road, W.
Frazer, Daniel, 113, Buchanan Street, Glasgow.
Greenish, Thomas, 20, New Street, Dorset Square, N.W.
Hampson, Robert, 205, St. John Street Road, E.C.
Hanbury, Cornelius, Plough Court, Lombard Street, E.C.
Mackay, John, 119, George Street, Edinburgh.
Richardson, John George Frederick, 10, Friar's Lane, Leicester.
Rimmington, Felix Marsh, 6, Ivegate, Bradford, Yorks.
Robbins, John, 372, Oxford Street, W.
Savage, William Dawson, 4, Park Road East, Brighton.

The following six nominees declined to accept office if elected:—

Davenport, John Thistlewood, 33, Great Russell Street, W.C.
Hills, Walter, 338, Oxford Street, W.
Morson, Thomas, 124, Southampton Row, W.C.
Radley, William Valentine, 74, Market Place, Sheffield.
Stoddart, William Walter, 9, North Street, Bristol.
Urwick, William Walker, 60, St. George's Road, Pimlico, S.W.

The Secretary also reported that the following five members had been nominated for election as Auditors, and had declared their willingness to accept office if elected:—

Barron, Frederick, 2, Bush Lane, Cannon Street, E.C.
Hodgkinson, William, 127, Aldersgate Street, E.C.
Horner, Edward, 20, Bucklersbury, E.C.
Squire, William, 5, Coleman Street, E.C.
Stacey, Samuel Lloyd, 300, Holborn, W.C.

The following being duly registered as Pharmaceutical Chemists were respectively granted a Diploma stamped with the seal of the Society:—

Brown, William Braithwaite.
Draper, James William.
Dutchman, Walter.
Hillier, Henry.
Radford, John Storer.
Riley, Charles Reynolds.
Tocher, John.
Twemlow, Francis Ernest.

Elections.

Members.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members of the Society:—

Aylesbury, William Thomas ...Weymouth.
Brown, William Braithwaite ...Preston.
Dutchman, Walter ....London.
Hillier, Henry ....London.
Radford, John Storer ....London.
Riley, Charles Reynolds ....London.
Twemlow, Francis Ernest ......London.

Chemists and Druggists.

The following registered Chemists and Druggists were elected Members of the Society:—

Clark, Willoughby ....Ilfracombe.
Drawbridge, Joseph George ...Liverpool.
Griffiths, Thomas ....Welshpool.
Hatfield, George Berney ....London.
Ormandy, John Stanley ....Barrow-in-Furness.
Stone, Frederick William ......Exeter.
Thomas, Caleb Jones ....Ystal-y-fera.

Associates in Business.

The following having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society:—

Minor.

Barlow, Frederick..................Birmingham.
Beesley, Thomas, jun. ....Salisbury.
George, Edward Robert ....Aylsham.
Gordelier, John Thomas ....Sittingbourne.
Harrison, John ....Dewsbury.
Kellett, Richard Edward.........Wigan.
Kirby, Frederick ....Northampton.
Mathews, Henry ....London.
Moore, Thomas Cooper ....Sunderland.
Morton, Henry ....London.
Murdoch, John McGill............Glasgow.
Platt, Jakeh Wright...............Shaw.
Purse, Alfred Dodds...............Sunderland.
Rhodes, Samuel......................Oldham.
Sherriff, George.....................Paignton.
White, Robert ....Sunderland.

Modified.

Buchanan, Dugald ....Irvine.
Parry, William ....Liverpool.
Tupholme, Edward Harland ...London.
Wearing, John ....St. Just.
Wilcox, William ....Lincoln.

Associates.

The following having passed their respective examinations and tendered their subscription for the current year, were elected "Associates" of the Society:—

Minor.

Franciosi, Eugène Auguste de...London.
Fraser, Andrew.....................Aberdeen.
Green, George ....Thetford.
Hemingway, Edward ....London.
Wylie, David Neil ....Edinburgh.

Modified.

Bunker, James ....Easton, Portland.
Haywood, Charles ....Liverpool.
Hughes, Thomas ....Denbigh.
Nix, John Beard ....Billericay
Pape, Tom..............................York.
Pill, Edward ....Helston
Richards, Alfred .... Hull.
Rogers, George Edward ....Birmingham.
Rossiter, William Henry ....London.

Apprentices.

The following having passed the Preliminary Examination and tendered their subscription for the current year were elected "Apprentices or Students" of the Society:—

Bird, William, Jun. ....Monkwearmouth
Carvell, John Maclean............London.
Dawson, John William ....Alford.

Dimmock, Frederick Augustus London.
Dingle, James Hender............Penzance.
Dove, George.........................Sherburn.
Fletcher, Thomas Henry ....Weston.
Foggitt, Thomas Jackson.. ......Thirsk.
Ground, Thomas ....Birmingham.
Hepworth, Frederick James ...Saltburn-by-the-Sea.
Hetherington, Thomas............Penrith.
Howard, Wilkins Rigg...........Burnley.
Hunter, William Sisson ....London.
Lawson, William Cooper.........Glasgow.
Newth, Francis Henry............Southampton.
Portway, John Bernard ....Bury St. Edmunds.
Radley, William Gibson ....Newton Abbot.
Redman, Joseph ....Rochester.
Reece, Thomas ... .Llandilo.
Roberts, George ....Dalston.
Snell, Charles Henry ....York.
Taylor, John ....Bolton.
Taylor, Samuel Mumford ......Notting Hill.
Welch, Charles ....Gosport.
Williams, Hugh ....London.

Several individuals were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The following names were restored to the Register of Chemists and Druggists:—

William Wilcox ....22, Guildhall Street, Lincoln.
William Lane Clarke...2, Nankin Road, Shanghai, China.

Honorary Members.

The Secretary drew attention to the fact that there were at present forty-seven names on the list of Honorary and Corresponding Members, fifty being the limit, and that it would be necessary to nominate now any person whom it was wished to elect at the next meeting of the Council.

Mr. Greenish begged leave to nominate Professor Dragendorff, of Dorpat University, and Professor Von Trapp, of St. Petersburg.

Reports of Professors.

Award of Bronze Medals.

The report of Professor Redwood on the first course of lectures on Chemistry and Pharmacy of the present session was read. It stated that there had been a marked improvement in the number of students, and in the attention paid and progress made. This was evidenced by the fact that fifteen students had competed for the bronze medal, the only prize offered, all the answers being satisfactory, five highly so. The numbers were 92, 88, 83, 72, and 70 per cent. respectively. The envelope bearing the motto of the successful competitor was then opened by the President, and found to contain the name of

Mr. Henry Ellis, of 11, Lower Phillimore Place, Kensington, to whom the bronze medal was voted accordingly.

Professor Bentley's report also spoke very satisfactorily of the good conduct, diligence, and progress of the students. There had been sixteen candidates for the bronze medal, the number of marks ranging from 80 to 35 per cent. On opening the envelope bearing the motto to which the highest number of marks had been awarded, it was found to contain the name of

Mr. Alfred Wright, of 16, Little Alie Street, Goodman's Fields, to whom the medal was ordered to be given.

Mr. Williams suggested that the professors should be requested in future to furnish in their reports the number of students attending the classes. This was agreed to.

Mr. Greenish said he should be glad to see an improvement in the mode of conducting the examination for these sessional prizes; viz., that they should be undertaken by some one independent of the professors who had delivered the lectures.

Mr. Williams said this question had been mooted on previous occasions, but had not been received with favour by the professors. He thought it better, therefore, not to press the matter at present.

Finance.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid. A balance sheet had been prepared and printed, and sent to every member of the Council.

Mr. Williams said the Society had been put to some expense in printing this balance sheet, and he should like to know of what use it was. If it were simply to be laid on the table and nothing said about it, it was a pity such an expense should be incurred. He should be glad to hear, therefore, anything which was to be said about it.

Mr. Hampson thought the expense would only be a few shillings, and though he admired the Treasurer's economical tendency, he thought the balance sheet contained very valuable information.

Mr. Mackay also thought the document a very useful one, and if no remarks were made upon it now, there might be on a future occasion. The only item which he was at all inclined to take exception to was the valuation of the Society's property in Scotland, which he considered much understated at £150.

Mr. Betty said that the very absence of questions and remarks showed the value of the balance sheet, and that it afforded all the information which could be desired.

Mr. Baynes asked how it was that while a certain percentage was written off several items for depreciation, nothing was written off the value of the lease.

The President said the lease was worth more instead of less, owing to the rise in the value of household property in the neighbourhood.

Benevolent Fund.

The Secretary having reported the result of further inquiries and the receipt of three letters respecting the widow of a chemist for whose benefit £10 had been placed in his hands two months ago, he was now authorized to place the money in the hands of a member of the Society residing in the applicant's neighbourhood, to be used as far as possible for the benefit of her two children.

The report of the Committee was read containing the following recommendations:—

£10 to the orphan daughter of a former member, making the eighth grant.

£10 to the widow of a pharmaceutical chemist.

£10 to a former member unable from ill health to earn anything by his own exertions.

£10 to the widow of a former member residing in Manchester.

The above recommendations were adopted, and a resolution was also passed authorizing the payment of the yearly allowance to annuitants.

Mrs. Moss, one of the annuitants, having died since last quarter day, the payment for the present quarter was ordered to be made for the benefit of her children.

Library, Museum, and Laboratory.

It appeared from the report of this Committee, that the average attendance in the Library had been for the past month, during the day, 20·875; in the evening, 8·45. In the conversation rooms, the average attendance had been 6·3. The circulation of books had been, in town, 158; in the country, 61, to 36 places.

The curator had reported that the attendance in the Museum had been on the average, in the day, 20; evening, 2. The average attendance during the past month showed an increase of 7 in the daytime, and a decrease of

1 in the evening. The curator had lent some specimens to the Sheffield Association for exhibition at a *soirée*, having previously obtained authority to do so; these specimens had been returned in good condition. Some duplicate specimens had been presented to the Sheffield Association and also to the Edinburgh Museum.

The following books were recommended to be purchased for the Library:—

'Traité pratique de la Détermination des Drogues simples,' by Professor Planchon.

'Das Chinin,' by Professor Binz.

Professor Attfield had reported that 85 students had attended his class since the commencement of the session, 60 being now at work.

The report and recommendations were received and adopted.

House.

The report of this Committee stated the results of the inquiries which had been made with reference to precautions against accident by fire upon the Society's premises. The subject was again referred to the Committee for further consideration and action.

Law and Parliamentary.

This Committee reported that it had met four times during the past month to consider the proposed amendments in the Adulteration of Food and Drugs Bill, and that a deputation had attended on two occasions at the Local Government Office, where they expressed their views to Mr. Clare Sewell Read.

Mr. Sandford said he had drawn up a memorandum showing what the deputation had explained to Mr. Clare Read as to the amendments which the Council thought desirable, and those to which objection was taken by it. A copy of this memorandum had been given to Mr. Clare Read. Mr. Sandford then proceeded to read through the memorandum, and said he believed the Government intended to insist on the retention of the word "knowingly," and the exception in clause 5 of additions not injurious to health, for the purpose of improving the appearance of the article. The penalty of £50 for the first offence, where the article was so adulterated as to be injurious to health, and imprisonment without the option of a fine, the proposed punishment for subsequent offences, had been pointed out to the Government as being unduly severe in the case of chemists and druggists who kept a large number of articles in stock, and differ considerably from dealers in articles of food; but it was considered that the retention of the word "knowingly" would meet any objection on that score. Amendments requiring an analysis to be made within a certain limited time after the article was purchased, that proceedings should be taken within twenty-one days, and that no summons should be returnable in less than seven days after the date of service were desirable. He was opposed to the amendment of Dr. Lyon Playfair, which would forbid the appointment of any person as analyst who was engaged in dealing in any of the articles likely to come within the operation of the Act, it being necessary that for the purposes of the Bill analysts should possess knowledge of the ordinary condition in which drugs could only be imported into this country.

Mr. Savage said the Council was much indebted to Mr. Sandford and the deputation for the way in which they had brought forward the claims of the trade, but he thought the Council should go still further and present a memorial to the Government, expressing what its feelings were. He knew some gentlemen were of opinion that the heavy penalty of £50 should be retained on account of the word "knowingly" being introduced, but for his part he believed the effect would be just the opposite to that intended, because the law would be evaded instead of being enforced. He would suggest, therefore, that a memorial should be presented to this effect:—

"That the Council of the Pharmaceutical Society is so strongly impressed with the importance of having a practical working Act of Parliament in connection with the adulteration of drugs, that notwithstanding it has already by deputation expressed its opinion of certain sections of the Act, it would urge by this memorial a further protest against the clause, which would in effect for a first offence impose a penalty of £50, and on every subsequent conviction leave no alternative but imprisonment."

He thought a maximum penalty of £20 for the first offence, with the alternative on repeated convictions of a fine of £40 or £50, or imprisonment for six months, at the option of the magistrate, would be much better. He would also suggest, in addition to the memorial, that they should further urge on the Government the important subject of appointing analysts as heretofore from amongst those practically acquainted with the subject, irrespective of their occupation.

Mr. Hampson thought it very desirable to have such a memorial, but suggested that a committee should be appointed to draw it up. He agreed with the two main points mentioned by Mr. Savage, but thought the wording might be improved.

Mr. Radley asked whether the Bill would affect compound medicines common in pharmacy, such as the "morning tonics" and "pick-me-ups," etc.

Mr. Sandford said an opinion had been expressed that these would come under the exception of any compound medicine supplied in accordance with the demand of the purchaser.

Mr. Schacht said the more this matter was discussed the more painfully it became evident that the idea of incorporating drugs and food together in one Bill was most unfortunate. They as druggists were endeavouring to fence themselves as much as possible from the infliction of penalties on account of the extreme delicacy of many of the operations which they had to perform, but in doing so they had to some extent to weaken the effect of the Bill in the public interest as affecting the dealers in food to which these delicate processes did not apply. The consequence was that their efforts to make this Bill a good bill for themselves would tend to make it a bad bill for the public, simply because it included too much. He wished to ask if any of those gentlemen who had been in communication with the Government had laid before it the desirability of separating drugs from food, and if it was absolutely imperative that they must sink or swim with sellers of provisions.

Mr. Owen said Mr. Lumley had stated distinctly that it was now too late to draw such a distinction.

Mr. Schacht said the more the matter was discussed the more difficulties multiplied, but he thought it would even now be well to throw a little more light on this subject, when perhaps those who had charge of the Bill might be induced to reconsider their position. He was quite satisfied that no six men at that table could agree upon exactly what they wanted; in fact, they could not define, for instance, what was injurious to health, and therefore the decision of these points was left sometimes to the option of magistrates and sometimes to juries. He hoped, therefore, they would not identify themselves so much with the Bill as would be involved by memorializing the Government.

Mr. Frazer agreed to a considerable extent with what had fallen from Mr. Schacht, and without reference to what had already been done he thought they should pause before adopting Mr. Savage's proposals. The heavy penalties imposed were intended to prohibit adulteration absolutely, and he should not like that Society, considering what it had done for the improvement of pharmacy, to in any way countenance a Bill which would protect the fraudulent dealer as against the public. With regard to the appointment of practical pharmacists as analysts, he sympathized a great deal with Dr. Playfair's amendment, because while perfectly conscious of the thorough honesty of the gentlemen appointed there was always a liability for the judgment to be warped by private interest, as had been shown, in fact, by the manufacturers on the Parliamentary Committee. His own opinion was there was not so much evil in the existing Act itself as in its administration.

Mr. Owen said Mr. Frazer's remarks induced him to support the memorial in order that the Council might to some extent leave its mark on the Act of Parliament. He suggested that whatever memorial were decided upon, it should be sent round to each member of Council in the form of a circular, so that he might bring it before the notice of any Members of Parliament with whom he was acquainted and thus, perhaps, exert more influence than by a memorial simply.

Mr. Robbins agreed with Mr. Schacht that if possible they ought now to make some attempt to separate food and drugs in any legislation to prevent adulteration, because what was applicable to food was not applicable to drugs. A chemist had an immense number of articles to keep in stock, and with many of them he could not possibly be acquainted before he received them, particularly as a large number were being constantly introduced. As far as he remembered, there had been very few cases indeed of chemists who had been prosecuted for fraudulent adulteration; the cases had been mostly those of sweet spirit of nitre, citrate of magnesia, milk of sulphur, and matters of that kind, in which it was impossible to say there had been any fraudulent intention. He though this ought to be brought before the Government; but they, as a Council, ought not to mix themselves up with the Bill.

Mr. Shaw had understood Mr. Sandford to say that the Government intended to retain the word "knowingly" in the new Bill, but there was a very strong feeling throughout the country with regard to this point, as evidenced both in the press and the comments of magistrates. Very recently one had stated that if it were retained there would be no more prosecutions. With regard to the working of the present Act, an analyst had taken upon himself lately to warn chemists and druggists with regard to the fact that citric acid and tartaric acid were frequently impregnated with lead. If they were to be prosecuted for such things, they must either have a guarantee from the seller, or test every article they sold, which would be simply impossible. At the same time he remembered not long ago acetate of lead was used in the preparation of candles, and thus there would be lead poisoning in the atmosphere.

Mr. Savage then moved a resolution to the effect that the preparation of a memorial in opposition to the objectionable clauses in the Adulteration of Food and Drugs Bill, having especial reference to the excess of penalties and the proposed amendment of Dr. Lyon Playfair, be remitted to a committee, consisting of the President, Vice-President, with Messrs. Sandford and Greenish.

Mr. Hampson, in seconding the motion, said he sympathized with Mr. Schacht and Mr. Frazer to a considerable extent, but they must make the best of circumstances, and the only way they could prevent an objectionable Bill passing was to use whatever power they had to improve it, and he thought a memorial might have some weight with the Government.

Mr. Betty said the question divided itself into two parts, first, should a memorial be sent at all, and in the second place, what should be contained in it. He suggested they should decide whether or not to memorialize the Government, and afterwards the matter of such memorial.

Mr. Williams thought it was all one question, because they could hardly decide whether they should send a memorial unless they knew what was to be put into it. He hardly thought it consistent after what had occurred at the interviews they had held with members of the Government to send a memorial with regard to the amount or the nature of the penalties. His own opinion was that they were excessive, and would check the operation of the Act, but he did not think the Council ought to commit itself to an opinion, one way or the other, upon the point.

Mr. Atherton understood that the Government intended to adhere to its former resolution allowing the appointment of pharmaceutical chemists as analysts, or anyone else who had suitable knowledge, and, that being the case, it seemed almost impertinent to recur to the subject again in a memorial.

Mr. Mackay thought they should first decide whether any memorial should be presented.

Mr. Schacht thought there would be a difficulty in the course suggested by Mr. Betty. His own opinion, which he should be glad if his colleagues concurred in, was set forth in the following sentence:—"That this Council having regard to the extreme difficulty of reconciling discrepancies of facts that apply to the falsification of articles of food and drugs is distinctly of opinion that legislation on the two subjects should be separate." If they held such views he did not think it would be worth while to memorialize the Government unless they did it in the way which they had been told it was now too late to adopt. He himself was not frightened at that argument, because he thought it was always well to speak the truth even at the last moment.

Mr. Mackay suggested that they might be guided by the result of Mr. Sandford's interview with Mr. Sclater-Booth on the following morning.

Mr. Savage said he should be quite willing, if Mr. Sandford would undertake to see Mr. Sclater-Booth, to let the sending of the memorial depend upon that gentleman's opinion whether it would strengthen his hands to do so.

Mr. Sandford said he should be happy to call on Mr. Sclater-Booth the next morning.

Mr. Hampson saw nothing incompatible in the two proposals. Appointing a committee need not clash with anything Mr. Sandford had to say as a private individual to Mr. Sclater-Booth.

The President then read the resolution as proposed to be put, referring only to the question of the £50 penalties, etc.

Mr. Betty said they were running counter to the opinion of the Government on this point, whose hands they would weaken whilst proposing to assist them in passing the Bill. The amount of penalty and the word "knowingly" must stand or fall together, but if it were understood that the memorial was only to be sent if Mr. Sclater-Booth approved of this course being taken he would support it.

It being understood that this should be done, and the names of Mr. Williams and Mr. Hampson being added to the Committee, the resolution was passed by a majority of 12 to 5.

> "That if a Select Committee, consisting of the President, the Vice-President, the Treasurer, Messrs. Greenish, Hampson, and Sandford, deem it desirable, a Memorial be presented to the Government praying that the penalties named in the Sale of Food and Drugs Bill be reduced, and that an alternative of fine or imprisonment be allowed in a repetition of offences."

The report of the Parliamentary Committee was then received and adopted.

The Conversazione in May.

The Committee appointed to make arrangements for the ensuing Conversazione reported that they had obtained the sanction of the authorities to the use of the South Kensington Museum on the 19th of May next, and detailed the steps they had already taken in the matter.

Report of Examinations.

ENGLAND AND WALES.

March 17th, 1875.

Mr. Schacht said it was to be remembered that last year a Committee was appointed to consider the whole matter of Preliminary examinations, when it was ultimately decided to reduce the number of centres. It was then understood that the superintendents for the examinations should be appointed for one year only, at the expiration of which time the subject was to be again brought forward. The result of the year's experience was now in the hands of the Council, from which it appeared that there were three centres at which no candidates had presented themselves, and several others where there had been two, three, or four only. The question then arose whether it was worth while to continue these places as centres or not. Of course it did not follow because in one year there had been few candidates that therefore they should be discontinued, but it was an open question whether the saving effected by omitting them would be sufficient to justify them in putting the individuals who would have presented themselves at those places to the trouble and expense of travelling to the next nearest centre. The utmost saving which could be expected by omitting those he had referred to would be from £30 to £35, and in some cases the candidates would have a considerable distance to travel, and perhaps be obliged to spend a night from home. He would therefore propose that the superintendents should be reappointed for all the towns on the list, with the exception of Dorchester, Hereford, Macclesfield, and Perth.

Mr. Savage thought some intimation should have been given before the names of these places were removed from the list, and that at least another year's trial should have been given.

Mr. Atherton was of the same opinion. It was hardly fair to discard a town after only one year's experience.

Mr. Mackay also thought it better to try the matter further before making any change.

Several other members having expressed themselves to the same effect, Mr. Schacht said he was very glad to find the opinion was so strong against the suggestion he had made, because he should be very happy to see the examinations continued at the whole of these places.

The Secretary suggested that it would be desirable, where possible, that the superintendence of the Preliminary examinations should be placed in the hands of the local secretaries, and, therefore, he thought it would be well to appoint the superintendents only for the next examination, making a fresh appointment in August, when the new list of local secretaries would be complete.

This suggestion was adopted, and the resolution passed unanimously—

> "That the superintendents and deputy-superintendents of the written examinations be re-appointed until August 1st next."

Preliminary Examination.

Mr. Atherton now brought forward the proposition which he moved at the last meeting, namely—

> "That the questions for the Preliminary Examinations after the present year, be prepared and reported on by the College of Preceptors."

He said this proposition had already been pretty well canvassed, and would not require much more to be said respecting it. It was rather curious, however, considering that it had been partially discussed, and reported, as showing how little interest was taken in the matter that not a single allusion had been made to it in correspondence in the Journal. He might say, however, that he had no intention whatever to sever the connection of the Council with the Preliminary examinations, but wished the Council should, as it always had done, make the examinations more or less stringent as circumstances might demand. In asking the College of Preceptors to conduct these examinations he thought they would not only be conferring a boon upon the examiners, but would be raising themselves and adding dignity to the Society by selecting persons specially qualified to conduct such an examination as the Preliminary. The same course was adopted by the College of Physicians and the Veterinary College, and communication having been opened with the College of Preceptors, it was ascertained that it was willing to undertake the task at about the same cost as was now incurred, the only difference, therefore, would be that the questions would be set and reported upon by the College of Preceptors, but the questions would be sent out by the Secretary of the Pharmaceutical Society, to whom the answers would be returned as at present.

Mr. Greenish seconded the motion.

Mr. Mackay regretted that he was not present at the last meeting, when this matter was discussed, but he had conversed with the Board of Examiners of Scotland on the matter, and he found that it was quite willing to act in accordance with the London Board, whose opinion on this matter it supposed would be sought by the Council. He thought there would be no difficulty in the matter from the explanation which had been given, because, though it was not a nice thing for any Board of Examiners to allow the reins to slip out of its hands, if it now clearly understood that the whole power would still be left in the hands of the Council, or the Board, that the appointment now proposed would only be made annually, and that the College of Preceptors would not be under the impression that it was to frame questions irrespective altogether of the opinions of the Council or the Board, he saw no objection to the proposal. He should be very sorry if the College set questions too severe for the purposes they had in view, because that would be a serious dead weight against young men entering the business and they had already had practical experience of the difficulty, which was constantly becoming greater, of getting young men into the business. His experience in Scotland had been that many young men, finding they were bound to possess a certain amount of classical knowledge, thought they might as well go further to one of the universities, and so fit themselves to commence medical studies. The College of Preceptors was a body unknown in Scotland, but he understood it was an authorized body of high character acting with a single eye to the advancement of education, and he should therefore be prepared to support the motion.

Mr. Savage suggested the addition of the words, "If such course be in accordance with the wishes of the respective Boards of Examiners."

Mr. Williams said they might postpone the question until the opinion of the Board of Examiners had been ascertained, but the Council must decide the question.

Some further conversation ensued on the question whether or not the College of Preceptors would be guided in the character of the examination by the wishes of the Council, and

The Secretary stated that he had been distinctly informed that it would do so.

The resolution was put and carried by a majority of 15 to 2.

Memorial from Glasgow.

The Secretary read the following memorial:—

"Unto the Honourable the Council of the Pharmaceutical Society of Great Britain.

"The Memorial of Pharmaceutical Chemists and Members of the Pharmaceutical Society and others engaged in the business of chemists and druggists in the city of Glasgow and surrounding towns,

"Showeth:—

"That your memorialists are members actively engaged in the trade or profession for which your honourable Council is appointed to legislate, and have the best interests of pharmacy at heart; being firmly of opinion that some of the regulations laid down for conducting the examinations of the Society are inimical to the future progress of our calling in this portion of the kingdom, and have in the past done much to estrange young men from becoming apprentices or students of the business, and, moreover, the mode of appointing Examiners, in Scotland especially, has been unfair to the great body of qualified pharmaceutical chemists throughout the country, and detrimental, in some respects, to the interests of the young men who have presented themselves, from time to time, for examination; and, further, are of opinion that the time has arrived when the provision made or contemplated in the Pharmacy Act of 1852 should be carried into effect, wherein it is enacted that:—

"'It shall devolve or be lawful for the Council of the Society, and they are hereby required, to appoint such fit and proper persons in *Scotland* to meet in *Edinburgh* or *Glasgow*, or such other place or places as the Council may think desirable, and to conduct all such examinations as are provided for and contemplated by this Act,' etc.

"Your memorialists therefore humbly pray your honourable Council shall take immediate steps to carry into effect the following suggestions, viz.:—

> "1st. That candidates presenting themselves for examination should have at least two opportunities given them to pass their respective examinations for one fee, as is the rule in other examining bodies in Scotland; that in case of failure in one or more subjects no fee be returned, but that they should receive due credit for the subjects in which they have passed, provided they succeed in more than one subject; and that, on presenting themselves a second time, they only be examined in the subject or subjects in which they have failed; that this rule apply to *all* examinations conducted by and for the Society.
>
> "2nd. That the Board of Examiners be balloted for from year to year, as in the election of members of Council, that is to say, a proportion should retire by rotation annually, and while being eligible for re-appointment, care should be taken that they be

chosen from a wider area than hitherto, and more from the general body of the qualified members of the Society in Scotland.

"3rd. That advantage be taken of the 9th Section of the Pharmacy Act 1852, referred to above, and that the Scottish Board conduct Examinations in Glasgow, at least *twice* a year, to save time, travelling expenses, and cost of living to the various candidates in the West of Scotland.

"And your memorialists will ever pray.

"Signed (in name and on behalf of the Pharmaceutical Chemists and Chemists and Druggists engaged in Glasgow and the West of Scotland in public meeting assembled, and approved by the Council of the Glasgow Chemists and Druggists' Association.)

"(Signed) JOHN CURRIE, Chairman,
" JAMES M. FAIRLIE, Secretary.

"*Anderson's University,* 204, *George Street, Glasgow.*
"30*th March,* 1875."

Mr. FRAZER said he hardly knew what was the proper course to take with reference to such a document, but he knew there was a very strong feeling on the subject in the West of Scotland, arising in a great part from the difficulty of getting assistants, and he was prepared to support the memorial if he knew the proper form of doing so.

Mr. WILLIAMS said there were three points in the memorial. One was the appointment of Examiners by ballot, which was obviously illegal. Another was the removing of the examinations from Edinburgh to Glasgow, which they had power to do; but when they considered that it required a laboratory and a considerable number of appliances in the way of specimens and other things, it would be seen that the expense would be a great deal more than that of bringing students from Glasgow to Edinburgh. The third point was as to the fees, on which his opinion was exactly the contrary to that put forward, because he believed they would have before long to increase the fees. He was quite of opinion that the examinations were not paying the Society, yet they would have to look to them as a source of revenue.

Mr. FRAZER, in answer to a question, said there were seven or eight persons present at the meeting at which the memorial was adopted.

Mr. BETTY moved that the petition lie on the table.

Mr. HAMPSON proposed that the discussion be adjourned until the next meeting of the Council.

Mr. MACKAY said he should unfortunately not be present probably at the next meeting.

The VICE-PRESIDENT thought they had better discuss the matter at once, or refer it to the Board of Examiners in Scotland for its opinion. One part of the proposition was evidently illegal, and with regard to having two examinations for one fee, no portion being returned, he thought if they altered the fees at all it would have to be in the opposite direction to that contemplated by the memorialists.

Mr. FRAZER said he did not want the matter to be shelved or to merely end in talk, but he should like to know what was the proper form in which to bring it before the Council.

Mr. SCHACHT thought the petition of any seven gentlemen well worthy of attention; but it would hardly be of sufficient importance to be discussed by the Council, especially as the questions were not now raised for the first time.

Mr. BETTY said the memorial impugned the honour of the Board of Examiners in Scotland, and, therefore, he thought the gentlemen so assailed ought to have the earliest opportunity of defending themselves; it was for that reason he had thought Mr. Mackay should have an opportunity of speaking at once upon the subject.

Mr. MACKAY said he rose with feelings of positive pain and regret on hearing this memorial from Glasgow, because had the Board in Edinburgh had the least idea of any such feeling existing in the minds of their Glasgow brethren, or that they were holding meetings for the purpose of producing such a memorial, a deputation from the Edinburgh Board would gladly have gone to wait upon them and very probably the memorial would never have been presented. But seeing it had been presented, he was bound to say there were some statements contained in it which could scarcely be supported. The causes of failure in the examinations had been thoroughly canvassed by the London Board, by the Edinburgh Board, and by the Council, and a deputation had come from Edinburgh to London, with the result of which visit they were acquainted. It was therefore unnecessary to revive that question in this memorial. As to the fees in case of failure he had nothing to say, except this, that the Edinburgh Board was of opinion that the fees were not paying the cost of examination, and that it would become necessary to increase their resources, which could only be done in one of two ways, either by raising the fees, which he was rather opposed to, or by making an unsuccessful candidate pay more than one guinea when he failed. With regard to the constitution of the Board it had been already stated that the method of election suggested was positively illegal. Their friends in Glasgow seemed to have incorrect ideas as to the constitution of the examining Board. Some two years ago, it was endeavoured to secure a fuller representation from Glasgow on the Board in Scotland, but the attempt signally failed. He could give the names of several gentlemen to whom personal application was made, but who refused to serve. In fact, if the whole of the present members were to resign, he did not believe it would be possible to persuade eight other competent men to fill their places. If, however, their Glasgow friends would send the names of qualified gentlemen from the West of Scotland, the members in Edinburgh would be very pleased to put them forward for election by the Council, in December next. With regard to the examinations being peripatetic, at the time when the provision to that effect was made it was believed that the examinations would be so simple in character that the examiners could take a little parcel of specimens, put it into their portmanteaus, go to any part of the country and conduct the examinations. He need not say, however, that the examinations were now of such a character and required so much manipulation and apparatus that a complete laboratory was required, and therefore he thought it a great pity, when they had just obtained a local habitation and needful appliances in Edinburgh, that their Glasgow friends should ask them to move all this machinery in order to conduct the examinations in Glasgow. If it were the fact that candidates for examination were principally young men from Glasgow and the West of Scotland, there might be more foundation for such a request, but on going through the lists he believed it would be found that the bulk of them came from all parts of Scotland and the North of England. If they once began to multiply centres it was impossible to know where to stop, and therefore he thought the only proper course was to confine the examinations to the parent Society in London and the North British Branch in Edinburgh.

Mr. FRAZER then said he would give notice of motion that at the next Council Meeting he would move that the matter be referred to the Law and Parliamentary Committee.

PETITION FROM STAMFORD.

The SECRETARY read a petition which had been received from Stamford, signed by six or seven persons, complaining that the Pharmacy Act of 1868 was not properly enforced, and stating that many persons not duly qualified were in the habit of selling the poisons mentioned in Schedule A to the Act.

Mr. Radley suggested that the same course might be adopted in this case as was done some time ago with regard to Sheffield, the Secretary writing to say that if particulars were forwarded of any breach of the Act he would bring it before the Council, and steps should be taken if necessary.

Mr. Hampson said this was a very good suggestion, or the petition might be referred to the Parliamentary Committee. He thought they ought not to be too inert in matters of this kind.

Mr. Betty said the petition betrayed such an utter want of information as to the working of the Pharmacy Act, and the powers of the Council under it, that he thought they need not seriously discuss it. The receipt might be acknowledged, and, of course, if any information were received of large quantities of poisons being illegally sold proceedings would be taken accordingly.

Mr. Schacht gave notice that at the next meeting he should propose an addition to the standing orders; that members of Council having the intention to introduce any motion of which notice had not been previously given should announce the same at the commencement of the day's proceedings. He did not mean to prevent any matter being brought forward which arose out of the business of the day, but if any gentleman came to the meeting prepared to move a particular resolution it was hardly fair that it should be left to the chance of coming on near the conclusion of the proceedings, when some of the members might have left, so that the subject could not be properly discussed.

PHARMACEUTICAL MEETING.

Wednesday, April 7th, 1875.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting were read and confirmed. The following donations to the Library and Museum were announced, and the thanks of the Society were awarded to the donors:—

Library:—'Transactions and Proceedings of the Botanical Society of Edinburgh,' vol. xi., part 3, and vol. xii., part 1, from the Society; Thomson's 'Conspectus of the Pharmacopœias of London, Edinburgh, and Dublin' (eleventh edition), Phillips's 'Translation of the London Pharmacopœia,' 1824 (second edition), and the 'Pharmacopœia Londinensis,' 1824, from Mr. R. C. Buckley; 'Chemical Examination of Alcoholic Liquors,' and 'Outlines of Proximate Organic Analysis,' from the author, Professor A. B. Prescott, M.D.; 'Ueber das Harz des Lärchenschwamms, von E. Masing,' from Dr. Dragendorff; 'The Durham University Calendar, 1875,' from the University.

Museum:—Fine specimen of Glacial Phosphoric Acid, from Mr. Morson; specimen of Goa Powder, from Mr. Postans; specimen of Guarana Seeds and Araroba, from Dr. Symes; Portrait of the Officers of the School of Pharmacy Students' Association, from the Committee; specimen of Witch Hazel Bark, from Mr. P. Squire.

Herbarium:—Specimens of *Daphne Laureola*, from Mr. G. C. Druce; specimen of *Ornithogalum nutans*, from Mr. T. W. Nettleship.

The President announced that Dr. A. W. Hofmann, of Berlin, who had come to this country for the purpose of delivering the Faraday lecture before the Chemical Society, had done the Pharmaceutical Society the honour of attending that evening for the purpose of bringing before it the specimens of substances which had been discovered or studied by Liebig. There were among the specimens many bodies interesting to pharmacists.

Dr. Hofmann, on coming forward, was greeted with loud and long continued cheering. He said that he thanked the meeting for the kind reception which they had accorded to him. He regarded it as due simply to the exertions which, at one time, it was his good fortune to make for the cause of chemical and—let him say—pharmaceutical education in this country. The two branches went hand in hand. There was before them a splendid collection of substances which had been discovered and examined by Liebig; but he must be excused from attempting a description of them, for he should not know where to commence or where to finish. In the summer of last year he received an invitation from the Council of the Chemical Society to deliver the Faraday lecture this year. It happened that that invitation was received almost on the same day of the month on which, a year previously, Liebig, his glorious master, had died. He immediately accepted the invitation requesting the council that they would allow him to select, as the subject of his lecture, the life-work of Liebig in chemistry, experimental and philosophic. He received by return of post a letter from the Foreign Secretary of the Chemical Society stating that the council heartily acquiesced in the proposal. Of course, he had from that moment to devote a large amount of his time to the preparatory readings for the lecture, and, as a matter of course, it soon became known among his pupils that he was, with all his might, exerting himself to do justice to the memory of his distinguished master. With that enthusiasm which was so characteristic of youth, some of the students associated in order to support him on that occasion, and they worked for months in order to enable him to submit to the chemists of England what was, probably, a more perfect and complete collection of the substances discovered and studied by Liebig than ever was—at all events simultaneously—under the eyes of Liebig himself. In speaking to a chemical fraternity, he needed not to dwell upon the time and energy which had been bestowed upon preparing these specimens, of which there were, perhaps, more than a hundred in number. He would, however, call attention to the beauty of some of the crystals and to the care bestowed by his young friends upon the classification of the substances. There was a peculiarity in that classification, for it would be found that some of the labels were white and some were blue. The white labels were applied to the substances which Liebig himself discovered, and the blue labels to those substances which had been discovered by others, but which he examined, and the composition and formulæ of which were established by his researches. It was quite out of the question to enter into the details of the collection upon that occasion; but the Society would feel interested in looking at it from two points of view. One was that they had the glorious result of a single life before them represented by what he might call an encyclopœdic display of his work; and the second point was that it showed the enthusiasm with which young chemists of our day most willingly gave up a very considerable part of their time for the sole purpose of exhibiting the labours of their grand countryman in the most conspicuous light to the chemists and pharmaceutists of this country.

The President said he was sure that he was speaking the sentiments of all present in saying that they were delighted and charmed, both by the presence of Dr. Hofmann, and by what he had shown them. There was no doubt that some day or other they would have quite as many valuable products which Dr. Hofmann himself had found; for there was no harder worker than Dr. Hofmann, to him work was a pleasure. His work was one of thought and investigation, undertaken with a desire to improve, as far as possible, everything connected, not only with chemistry, but with all that related to social life. Dr. Hofmann had shown himself to be ready on all occasions to do all that he possibly could do to ameliorate the conditions of society. He (the President) was sure that they must heartily welcome and thank him upon this occasion.

Identity of Goa Powder and Araroba.

A paper on this subject was read by Mr. E. M. Holmes. It is printed at p. 801, and gave rise to the following discussion:—

Mr. Plowman said that on the previous day Mr. Holmes had placed in his hand three samples of powder, which he had submitted to chemical examination; but in consequence of want of time the examination had been imperfect. One was a sample of Goa powder which had been presented to the Museum by Mr. Postans; the second, a sample of Goa powder which had been in the Museum for eleven years; and the third was a specimen of araroba. As Professor Attfield had found that chrysophanic acid was a chief constituent of araroba, he (Mr. Plowman) sought for that body. He exhausted each specimen with benzol, and from the Goa powder presented by Mr. Postans, he obtained 87 per cent. of soluble matter. From the Goa powder which had been in the Museum eleven years, he got 70 per cent. of soluble matter; and from araroba he got 84 per cent. The fact of the araroba powder giving less soluble matter than the Goa powder presented by Mr. Postans might be due to the fact that there was some woody matter mixed with it. The benzol solution upon evaporation deposited tufted crystals, which when examined gave the characteristic reactions of chrysophanic acid. The deposit, from the Goa powder which had been in the Museum eleven years, was somewhat crystalline; but the crystals were not definitely tufted as in the other case. The fact of the percentage of soluble matter being so much lower was, probably, due to the chrysophanic acid having become changed by keeping. From the results which he had obtained, he had no doubt that the araroba and the Goa powder presented by Mr. Postans were identical; and the probability was that the Goa powder presented eleven years ago was also identical, but that some change had taken place through keeping. The colours differed considerably, and, probably, the crystalline quality had been affected.

Professor BENTLEY said that he well recollected the discussion on Goa powder in that room eleven years ago. It showed how little they knew of the interest with which a substance then presented to the Society might be viewed many years after. He remembered that in that discussion the subject was thought by some present to be scarcely worthy of the notice of the Society. Goa powder had now, however, become an important remedy in skin diseases, and was peculiarly valuable in some intractable forms of skin disease which prevailed in India and China, though not so much in this country. It was, therefore, of importance to ascertain whether Goa powder and araroba were one and the same substance. The investigations seemed to show that they were identical. Probably they would not be able to tell the exact origin of araroba until the cuttings of the plant yielding it, which were now in the Botanical Gardens at Edinburgh, were sufficiently grown to be identified by botanists; but if the substance was derived from the plant it was supposed, or an allied species, the change of colour noticed in the paper was what they would expect, for many of the woods of those plants were used as dye woods. Thus, South American species of *Cæsalpinia* yielded, at least, three dye woods, namely, peach wood, Brazil wood, and Braziletto wood. Chemists knew that various tints, such as rose and yellow and red, could be obtained from these different woods, and even each particular wood would undergo a change of colour according to age and exposure. One species of *Centrolobium*, which was allied to the *Cæsalpinia*, also yielded an orange wood. This species was a native of the northern parts of South America. The orange wood upon keeping would become brown. Doubtless everyone who kept these woods knew that they would alter their colour very much from exposure. He, therefore, agreed with the statement in the paper that any slight difference of colour was a matter of no importance as to the identity of Goa powder and araroba. Mr. Holmes had stated in his paper that *Centrolobium robustum* was probably the plant which yielded the araroba powder. He had now told them that the leaves of the plant which he had since received showed its origin more probably to be a species of *Cæsalpinia*. He (Professor Bentley) believed the latter to be correct. Mr. Holmes spoke of *Centrolobium robustum* as yielding "the well-known zebra wood." He (the speaker) was not quite sure upon what authority that statement was made; but, probably, upon the authority of Martius, from whom an extract was given in the paper. The more recent investigations, however, of Schomburgh, showed that zebra wood was derived from *Omphalobium Lamberti*, a tree which grew in Guiana, and belonged to a totally different natural order, namely, the *Connaraceæ*, although some had supposed it to be derived from *Guettarda speciosa*, a cinchonaceous plant. He knew of no reliable evidence that the zebra wood of commerce was derived from *Centrolobium robustum*. He thought that the investigations of Mr. Holmes and others clearly showed that the two substances, Goa powder and araroba, were identical, and that the origin of them both was some leguminous plant. Probably it would be found from a species of *Cæsalpinia* or some nearly allied genus; for, as already noticed the woods of these trees varied very much in colour, and could be made to take a variety of tints by the action of reagents, and even by the action of the air and light. With regard to the action of dock, of course it was well known that dock-root had been used from the earliest period in cutaneous affections. There was a fashion in medicine, as in everything else, and perhaps some of the younger members of the Society would see the day when some of the old remedies were brought into use again. Chrysophanic acid was found in some docks, and if it were found to be the active principle of Goa powder, docks might come into use again. Dock was used in the time of Linnæus, and it was still used largely in Sweden in scurvy and in many cutaneous disorders. It was formerly sold in the herb shops of this country as *radix et herba britannica*. Dr. Garrod, some years ago, particularly called the attention of the profession to the use of some docks in skin diseases. It would be a very curious incident in reference to a subject which was thought of very little importance eleven years ago, if the active principle of Goa powder and the active principle of dock should prove to be the same.

Professor ATTFIELD said that the casks of araroba to which Mr. Holmes had referred in his paper, and which were exposed for sale in the London market last year, were, he believed, purchased by Mr. Kemp, of Bombay, who sent over to this country the Goa powder about which there had been lately some discussion. With regard to the identity of Goa powder with araroba powder or chrysarobine, he had examined several specimens which had been sent to him at different times under different names. He examined a sample which, eleven years ago, was sent by Mr. Kemp to one of the most eminent pharmacologists which this country had ever seen, and whose absence they must all regret. He referred to Mr. Hanbury. He had also examined a specimen which was presented to him four or five years ago as "genuine Goa powder;" and he had also witnessed the experiments made by Mr. Holmes on three or four specimens, the nature of which had been detailed in the paper. He had not the slightest hesitation in saying that the specimen which was given him four or five years ago as "genuine Goa powder" was spurious, and was simply what was known in England as cudbear. It was this specimen which he alluded to at the March Pharmaceutical Meeting as being entirely distinct from araroba powder. He had also no hesitation in saying that the specimens he had examined since, the sample which was sent to this country eleven years ago by Mr. Kemp, and the samples which had now been brought to the attention of the Society, were all identical, whether known as Goa powder, araroba powder, arariba powder, or chrysarobine. With regard to the varying colour of the substances, it was possibly, if not probably, due to the conjoined action of the oxygen of the air and traces of ammoniacal gas in the atmosphere. Samples of chrysarobine kept in his laboratory underwent change of colour far more rapidly than samples kept in his own house, and he need not remind the meeting that the atmospheres of those two places would probably differ somewhat as regarded the percentage of ammoniacal compounds which they contained. He cordially agreed with what had fallen from Professor Bentley, with regard to the importance of paying attention even to what might appear to be the most trifling or uninteresting substances brought before them from the colonies or from foreign countries. Dr. Hofmann had reminded them of the indebtedness of chemistry to pharmacy. The substance before them was extremely rich in chrysophanic acid, a compound which had not been exhaustively investigated. Here then was another instance of pharmacists presenting to chemists one more substance, the chief component of which would probably form the subject of many researches.

Mr. Moss said that it might be worth while to mention, in passing, that the parcel of araroba referred to by Mr. Holmes and Professor Attfield was by no means the first which had appeared in the London drug market. On the contrary, araroba had been received into this country for many years, but the imports had found their way almost entirely into the hands of one firm, which had again exported the whole, he believed, to the East Indies. If this were so, the fact, taken in connection with the many recent notices of araroba, would go far to remove the mystery in which the origin of Goa powder has been long enshrouded.

Mr. Postans, after alluding to Professor Attfield's research on chrysarobine, said that about a year ago, having, at the request of a customer, to procure some Goa powder, he obtained a supply from Bombay, and took the opportunity, with the concurrence of some medical friends, of testing its powers as a remedy for ringworm, on the forehead of his own little girl. Following directions received he moistened the part with water, and rubbed over it some powder. This treatment repeated for three or four days effected a cure. But particles of the powder were apt to get into the eyes, causing irritation. Subsequently, therefore, when the ringworm appeared on the scalp he used a paste of Goa powder with oil. The operation of washing, however, distributed the colouring matter of the powder over the girl's hair, converting it from auburn to ugly purplish-brown. Similar effects were afterwards described in a paper by Mr. Gaskoin. It would appear, therefore, that while a pomade or ointment, or oily mixture, was the appropriate vehicle for Goa powder, care must be used both in applying and removing tho preparation.

A paper entitled :—

"Notes on the Pharmacy of Atropine,"

was read by Mr. W. Willmott. It is printed at p. 802, and gave rise to the following discussion :—

Mr. Linford said, with regard to the statement that a solution of atropine might keep perfectly well in the laboratory and yet become perfectly acid during use, it had occurred to him that it was not improbable that the acid was derived from the secretions of the patient's eyes. And not only might the solution become acid, but dust and other solid matters might be conveyed to it during use ; for patients were in the habit of applying the solution with a camel's hair brush, and putting the brush into the bottle. He had seen atropine in use in a patient's house, and in that case the bottle was kept on the mantelpiece and the brush was kept in a tray by the side of it.

Mr. Williams said that he was hardly able to give an opinion as to the presence of dust in the solution of atropine ; but he knew, or believed he knew, that certain atropines, or so-called atropines, irritated the eye when applied, while others seemed not to possess the same property. There had been a controversy between German chemists and English chemists on the point. German chemists had said that English chemists used belladonine and not atropine ; and English chemists retorted that the German chemists had sent us belladonine, and that English chemists made atropine. It would be a very interesting subject of investigation whether belladonine or atropine was the irritating substance, if the irritation was due to either of them. The paper tended to prove that mechanical agency rather than chemical constitution was the cause of the irritation.

Dr. Hofmann said that he scarcely knew that he was in a position to throw any light upon this interesting and important question; but being called upon to offer a few remarks, he would direct their attention to the fact that there was a sample of atropine among the specimens which he had exhibited on the table; being one of the substances examined by Liebig at an early date, soon after he had elaborated his method of analysing substances and constructed his five-bulb apparatus. He (Dr. Hofmann) had not paid special attention to the subject of atropine, for there being so large a domain to be explored, each man had to select a special field on which to work, though at the same time he must endeavour as far as possible to remain familiar with what his neighbours were doing on the right and on the left. As far as his (Dr. Hofmann's) impression went, the chemical investigation of atropine had by no means been carried to such a point that it could be said to be complete. He thought that it was very important that atropine and a considerable number of other "*ines*" should be much more minutely examined. It was his belief, however, that chemists were at the present moment deeply impressed with the necessity of returning to the examination of the bodies presented to them by nature rather than of those obtained by the artificial processes of metamorphosis, and he was sure that the investigation of the former would still yield rich harvests of most valuable and frequently quite unexpected results. He might be allowed to allude to the recent examination of vanilline, a substance which occurred in the vanilla plant. Vanilla had been repeatedly examined. It had been examined by himself, by Carles, in France, and by two young German chemists, of the names of Tiemann and Haarmann, working in the Berlin laboratory. When the composition of vanilline had been established beyond doubt by a multiplicity of experimental researches such as had never been applied to atropine and the great majority of the alkaloids, suggestions were repeatedly thrown out as to modes of producing vanilline artificially, and they all knew that last year it was actually produced artificially from a crystalline substance having a very close analogy to it, and which was found in the juice of the fir tree. Here they had the starting point of a new chemical industry. The crystalline body obtainable from the juce of the fir tree, and which was called coniferine, could be procured in any quantity, and Messrs. Tiemann and Haarmann had collected not less than 100 kilog. of it in the course of a single summer. Coniferine, by a simple process of oxidation was converted into vanilline, and although some difficulty still existed on carrying out this oxidation upon an industrial scale, he had no doubt that artificial vaniline would soon compete with the natural product in the market. This instance showed the enormous advantages which might be obtained from a more minute and accurate examination of the bodies with which nature presented us. They must not, of course, expect every day to light upon such a vein as was opened up by the investigation of coniferine ; but he had no hesitation in stating his belief that every well-conducted examination of vegetable substances would amply repay the time and labour bestowed upon it. He might be allowed to remind the members of the Pharmaceutical Society that during the last few years he had been frequently engaged in the examination of essential oils which occurred in plants, and that nearly all of them he had found to be substances having great interest. There was, for instance, that class of bodies which chemists designated by the name of nitriles, artificially obtained by the withdrawal of water from amides. He had investigated nearly a dozen of the essential oils of plants and he had found that they were all nitriles of acids with which chemists were long acquainted. Thus the essential oil of *Tropæolum majus* and of *Lepidium sativum*, was found to be the nitrile of toluic or phenyl-acetic acid.

The oil of *Nasturtium officinale*, the nitrile of hydro-cinnamic or phenyl-propionic acid. Or he might remind them that the oil of *Cochlearia officinalis* had proved to be the mustard oil of the secondary butyl-alcohol. These results were decidedly of a nature to induce chemists to take up again the study of substances produced under the influence of plant-life. There was, indeed, an unmistakable tendency in that direction, and thus it would be seen, that chemistry, which owed its very origin to pharmacy, was now, after having almost forgotten this early association, returning in a measure to the source and fountain-head, accepting as it did most gratefully the endless variety of subjects, which the researches in pharmacy and the natural sciences allied with it, were daily presenting for inquiry.

Ergot and its Liquid Extract.

A paper on this subject was read by Mr. A. W. Gerrard. It is printed at p. 805, and gave rise to the following discussion:—

Mr. Hampson said that he had used a similar process to that described by the reader of the paper; namely, the use of cold water without the previous use of ether, and the product was very satisfactory.

Mr. Linford said that many years ago he made a cold water extract of ergot upon the same principles as had been stated that night; but with regard to the quantity of alcohol used, he had a perfect recollection that 25 per cent. of alcohol in the solution did not prevent so much fermentation in the preparation as to make it rather strongly acid in a few months. These experiments were conducted for Mr. Bullock with whom he (Mr. Linford) was living at that time—more than twenty years ago. It was a very great advantage when they made a cold water extract of ergot and had evaporated it, to add the alcohol before the extract was cold, because the albumen was separated much more easily, and the extract was easily filtered through paper while still warm. If the evaporated solution was allowed to become cold before the alcohol was added it was almost impossible to filter it through paper.

The President announced that the present meeting was the last of the session. He hoped that gentlemen would devote the recess to investigation and the preparation of papers for the next session. He again expressed the thanks of the society to Dr. Hofmann for his kindness in coming to the meeting that evening.

EXAMINATIONS IN EDINBURGH.

March 30th and 31st, 1875.

Present: Messrs. Ainslie, Buchanan, Gilmour, Kemp, Kinninmont, Noble, Tait, and Young.

MAJOR EXAMINATION.

Two candidates were examined. *One* failed. The following passed and was declared qualified to be registered as a Pharmaceutical Chemist:

Tocher, John........................Aberdeen.

MINOR EXAMINATION.

Eighteen candidates were examined. *Seven* failed.

The following *eleven* passed and were declared qualified to be registered as Chemists and Druggists:—

Sawyer, Henry......................Carlisle.
Equal. { Chadwick, George Nicholas ...Dewsbury.
Equal. { Walton, Edward Bridges.........London.
Kellett, Richard Edward.........Wigan.
Allan, Alexander ....Aberdeen.
Equal. { Joures, Robert ....Edinburgh.
Equal. { Lett, Arthur Joseph ....Manchester.
Williams, William ....London.
Panton, William Alexander ...London.
Peacock, John Rutherford ......Glasgow.
Edward, John Hutchison ......Edinburgh.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

One candidate was examined, but failed to pass.

EXAMINATION IN LONDON.

April 2nd, 1875.

Present: Messrs. Allchin, Barnes, Bottle, Carteighe, Corder, Gale, Haselden, Linford, Martindale, Moss, Schweitzer, Taylor, and Umney.

MODIFIED EXAMINATION.

Twenty-six candidates were examined. *Twelve* failed. The following *fourteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Boutall, George Squire...........Ramsgate.
Bunker, James ....Easton, Portland.
Hall, Frederic John ....Leamington.
Haywood, Charles.................Liverpool.
Jones, David........................Uphill.
Knight, John Edward............London.
Manthorp, Frederick William...Colchester.
Nix, John Beard ....Billericay.
Pape, Tom..........................York.
Pill, Edwin ....Helston.
Smith, John Sykes ....London.
Smith, Robert George ....Liverpool.
Wearing, John ....St. Just.
Webster, Thomas..................Beaumaris.

PRELIMINARY EXAMINATION.

The undermentioned was received in lieu of the Society's Examination:—

Certificate of the University of Cambridge.

Foggitt, Thomas Jackson ......Thirsk.

MEETING OF THE NORTH BRITISH BRANCH.

The fifth meeting of the present session was held in the Society's Rooms, 119, George Street, on Friday evening, 26th ult., at half past eight o'clock. Mr. W. Gilmour, President, in the chair. Before the business of the evening commenced the President made allusion to the loss which the cause of pharmacy generally, and the Pharmaceutical Society in particular, had sustained by the sudden and unexpected death of Mr. Daniel Hanbury.

Mr. Blanshard laid on the table a sample of Rangoon wood oil, fifteen casks of which had been offered to his firm for the purpose of making balsam of copaiba. Of course, not being manufacturers of such an article, the offer was politely declined. In all its characteristics it appeared to be an impure Gurjun oil. The sample was presented to the Museum.

A paper entitled "Notes on Aloes, with Special Reference to the Action of Changed Aloin and Resin of Aloes," was read by William Craig, M.D., F.R.S.E., and Lecturer on Materia Medica.

Before proceeding to deliver the lecture Dr. Craig asked permission to address a few words to pharmaceutical students regarding the order of their academic studies. He said the great aim of the student was not merely to get good from the class he attends, but to get the greatest possible amount of good from that class. This can only be obtained by attending the classes in a certain rotation. There were three classes which the Pharmaceutical Society recommend their students to attend—botany, chemistry, and materia medica. It would be well for pharmaceutical students to be conversant with all of these subjects, and they ought to be studied in the order stated above. It is not desirable that any two of these classes should be taken simultaneously, and they may all be attended separately in the space of fifteen months. Botany naturally came first, a class that was only taught in summer; and he might say that the students in Edinburgh have opportunities of acquiring a knowledge of botany superior to those possessed by any other students in the kingdom. He would also call the attention of the students to a prize which is given for the best herbarium, as a prize which ought to be gained by a student of the *North* British Branch of the Pharmaceutical Society. He believed he was correct in stating that no teacher of botany in the kingdom had done so much for practical botany as Professor Balfour. A keen enthusiast in his favourite science, he had succeeded in infusing enthusiasm into many of his pupils, and by his weekly excursions into the surrounding country he afforded the means of collecting a fine herbarium. Within a radius of 20 miles around Edinburgh, upwards of 1000 species of phanerogamous plants and ferns may be collected, and were collected a few years ago by Dr. Isaac B. Balfour. Having attended botany in the summer, the student should attend chemistry the following winter. Materia medica should be taken in the summer after chemistry. It is this class more than any other which united the members of the medical profession to members of the Pharmaceutical Society. As he had the honour last summer of lecturing on materia medica to several students of pharmacy, he thought it his duty to take this opportunity of advising the students regarding the order of their academic studies, and he was confident that if they adopted the order which he had indicated, they would find that it had not been accepted without considerable advantage.

Dr. Craig's paper was illustrated by numerous tables, coloured drawings, and diagrams, and he had also on the table a specimen of Socotra Aloe plant, sections of the leaves of which showed abundant exudation of the juice.

After some remarks on the watery extract of aloes by Mr. Ainslie and others, a vote of thanks was very cordially awarded to Dr. Craig for his interesting paper.

Dr. Craig's paper will be printed in an early number.

Mr. John Mackay then read a paper on the Solid and Liquid Japanese Oil of Peppermint. We are compelled by want of space to defer the printing of this paper also.

The specimens submitted to the meeting were handed to the Museum.

Mr. Blanshard moved a vote of thanks to Mr. Mackay, which was carried unanimously.

Parliamentary and Law Proceedings.

Pharmacy Bill for Ireland.

The following is the draft of a Bill proposed by the Chemists and Druggists' Society of Ireland, to institute a Pharmaceutical Society in Ireland, and to regulate the Sale of Poisons.

Whereas a great deficiency exists throughout Ireland of establishments and shops for the sale of medicines and compounding of prescriptions, and great inconveniences thereby arise to the public in many parts of the country, it is expedient that a Pharmaceutical Society should be instituted for Ireland, and that the licentiates of said society, registered under this Bill, may keep open shop for the dispensing and compounding of prescriptions of duly qualified medical practitioners; also that a register should be kept of chemists and druggists who sell poisons.

And whereas, it is expedient and necessary that such persons should possess a competent practical knowledge of their business, and to that end, that from and after the day herein named, all persons should, before commencing such business, be duly examined as to their qualifications and practical knowledge, and that registers should be kept, as herein provided.

Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the lords spiritual and temporal, and commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. From and after   One thousand eight hundred and seventy-   , it shall be unlawful for any person, other than a duly qualified pharmaceutical chemist or licentiate of the Apothecaries' Hall, to keep open shop for dispensing or compounding medical prescriptions in Ireland, and registered under this Bill.

2. Pharmaceutical chemists within the meaning of this Bill shall consist of all persons who shall be duly examined and licensed in pharmacy, and registered as pharmaceutical chemists or pharmacists under the provisions of this Bill.

3. Chemists and druggists within the meaning of this Bill, shall consist of persons who have kept open shop for the sale of drugs and poisons before the passing of this Bill, and of those who shall be duly registered under this Bill as hereinafter specified.

4. It is hereby enacted that a Pharmaceutical Society shall be instituted, to be called the "Pharmaceutical Society of Ireland;" and authority is hereby given for the formation of such society; and in order to the formation of same, in the first place, twenty-four fit and proper persons be and are hereby named to form the first council (one-third of whom retire by rotation each year, but may be eligible for re-election), with power to make certain by-laws and appoint examiners, and lay down a scheme of examinations, subject to the approval of the Lord Lieutenant, it shall be lawful for every person who has been duly licensed and registered as a pharmaceutical chemist by this Bill, and also for every duly qualified apothecary, upon payment of an annual subscription of one guinea each to the treasurer appointed under this Bill, to become a member of said society, and to have a voice and vote in all general meetings of the society; and the Council of the Pharmaceutical Society are hereby authorized and required, within one year after the passing of this Bill, to convene a meeting of all members of the society, to be held in Dublin, at such place as may be agreed on, by written or printed summonses, to be issued ten days previous to the day agreed upon for holding such meeting; and it shall be lawful for the members in assembly at such meetings to appoint a president, vice-president, council, and secretary, for conducting the business of the society; and like meetings of the society shall be holden annually. And it shall be lawful for said council to arrange at any time with the Council of the Pharmaceutical Society of Great Britain for a reciprocity of privileges and practice between the legally registered pharmaceutical chemists, and chemists and druggists, respectively, throughout the United Kingdom.

The following are the persons named to form the first Council:—Sir Dominick Corrigan, Bart.; Dr. Rawdon MacNamara; Dr. Aquilla Smith; Dr. William Frazer; Dr. Charles H. Leet, L.A.; Thomas Collins, L.A.; Henry N. Draper, C. and D.; Charles R. C. Tichborne, Professor of Chemistry; Edward M. Hodgson, C. and D., President; William Hayes, C. and D., Secretary; John Goodwin, C. and D., Treasurer; William Allen, C. and D.; J. T. Holmes, C. and D.; Stanley Oldham, C. and D.; Robert Simpson, C. and D.; Charles Johnston, C. and D.; Patrick Bermingham, C. and D., Dublin; Thomas R. Lester, C. and D., Cork; John Laird, C. and D., Limerick; Henry Bell, C. and D., Waterford; A. E. Doran, C. and D., Bray; Thomas G. Peel, C. and D., Armagh; W. R. Hamilton, C. and D., Newry; Samuel J. Conolly, C. and D., Athy.

5. All such persons as shall have been so appointed to conduct examinations under this Bill shall be, and the same are hereby declared to be, fit and proper persons to conduct all such examinations as are provided for or contemplated by this Bill, and shall respectively have full power and authority, and are hereby authorized and required to examine all persons who shall present themselves for examination under the provisions of this Bill in their knowledge of the Latin and English languages, in arithmetic, in botany, materia medica, in pharmaceutical and general chemistry, in practical pharmacy, in the British Pharmacopœia, and such other subjects, as may from time to time be determined by any by-law of the General Council of the Pharmaceutical Society of Ireland. Provided always that such examinations shall not include the theory and practice of medicine, surgery, or midwifery, or any branch of medicine or surgery; provided,

nevertheless, that in case of rejection, a rejected candidate may present himself for re-examination after six months.

6. The Council of the Pharmaceutical Society of Ireland shall have power to appoint and dismiss at any time a registrar, and such clerks and other officers as may be requisite for carrying out the purposes of this Bill, and also to pay suitable salaries to the said registrar, treasurer, clerks, and officers.

7. For every examination and registration, and for every certificate of same, such reasonable fees or charges shall be paid as shall from time to time be fixed and determined by any by-law to be made by the Council of the Pharmaceutical Society, provided always, such fees or charges shall at no time exceed the fees laid down respectively in each case in Schedule (A) to this Bill annexed, and such fees shall be paid to the treasurer, and shall by him be applied as the said Council of the Pharmaceutical Society shall direct in furtherance of the provisions of this Bill.

8. The registrar to be appointed under or by virtue of this Bill shall from time to time make out and maintain a complete register of all persons certified as pharmaceutical chemists by the examiners appointed under this Bill, also a separate register of all persons certified in like manner as chemists and drugists, and also as apprentices, students, or assistants, respectively, and shall keep a proper index of the registers, and such other registers and books as may be necessary for giving effect to the by-laws which shall from time to time be made in conformity with the provisions of this Bill. But no name shall be entered in the register, except of persons authorized by this Bill to be registered, nor unless the registrar be satisfied by the proper evidence that the person claiming is entitled to be registered; and any appeal from the decision of the registrar may be decided by the Council of the Pharmaceutical Society; and any entry which shall be proved to the satisfaction of such Council to have been fraudulently or incorrectly made, may be erased from, or amended in, the register, by order in writing of such Council.

9. It shall be the further duty of the registrar to make and keep correct registers, in accordance with the provisions of this Bill, of all persons who shall be entitled to be registered under this Bill, and to erase the names of all registered persons who shall have died, and from time to time to make the necessary alterations in the addresses of the persons registered under this Bill. To enable the registrar duly to fulfil the duties imposed upon him, it shall be lawful for the registrar to write a letter to any registered person, addressed to him according to his address on the register, to inquire whether he has ceased to carry on business, or has changed his residence, such letter to be forwarded by post as a registered letter, according to the Post Office regulations for the time being; and if no answer shall be returned to such letter within six months from the sending of the letter, a second of similar purport shall be sent in like manner, and if no answer be given thereto within three months from date thereof, it shall be lawful to erase the name of such person from the register, provided always, that the same may be restored by direction of the Council of the Pharmaceutical Society, should they think fit to make an order to that effect.

10. The registrar shall, in the month of January, in every year, cause to be printed, published, and sold a correct register of the names of all pharmaceutical chemists, and a correct register of all persons registered as students, apprentices, and assistants, also a correct register of all persons registered as chemists and druggists, and in such registers respectively, the names shall be in alphabetical order, according to the surnames, with the respective residences, in the form set forth in Schedule (B) to this Bill, and such printed registers shall be called "The Registers of Pharmaceutical Chemists, and of Pharmaceutical Students, Apprentices, and Assistants, and of Chemists and Druggists for Ireland," and a printed copy of such registers for the time being, purporting to be so printed and published, as aforesaid, or any certificate under the hand of the said registrar, and countersigned by the President or two members of the Pharmaceutical Society, shall be evidence in all courts, and before all justices of the peace, and others, that the persons therein specified are registered according to the provisions of this Bill, and the absence of the name of any person from such printed register shall be evidence, until the contrary shall be made to appear, that such person is not to be registered according to the provisions of this Bill.

11. Any registrar who shall wilfully make, or cause to be made, any falsification in any matter relating to the said registers, and any person who shall wilfully procure, or attempt to procure, himself to be registered under this Bill, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, and any person aiding or assisting him therein, shall be deemed guilty of a misdemeanor, punishable by fine or imprisonment, and shall, on conviction thereof, be sentenced to be fined or imprisoned for any term not exceeding twelve months, and not exceeding 20*l*.

12. Every registrar of deaths in Ireland, on receiving notice of the death of any pharmaceutical chemist, or pharmaceutical student, apprentice, or assistant, or of any chemist and druggist, shall forthwith transmit by post to the registrar under this Bill a certificate, under his own hand, of such death, with the particulars of the time and place of death; and on receipt of such certificate, the said registrar under this Bill shall erase the name of such deceased pharmaceutical chemist, or student, apprentice, or assistant, or chemist and druggist, as the case may be, from the register, and shall transmit to the said registrar of deaths the cost of such certificate and transmission, and may charge the cost thereof as an expense of his office.

13. From and after the
one thousand eight hundred and seventy- , any person who not being a duly registered chemist and druggist, or pharmaceutical chemist, shall keep an open shop or wareroom for the retailing or dispensing of poisons, as set forth in the Poisons Act of 1870, "to regulate the sale of poisons in Ireland," or which may be hereafter added according to the provisions of said Act, provided that the exceptions therein specified, with respect to the duly qualified apothecary, shall also apply to the pharmaceutical chemist registered under this Bill; or any person who, not being a duly registered pharmaceutical chemist, shall keep an open shop or wareroom for the dispensing or compounding medical prescriptions, or who shall take, use, or exhibit the name or title of pharmaceutical chemist, or pharmaceutist, or pharmacist, or dispensing chemist, or chemist and druggist in Ireland, or make use of any sign or title, implying that he is registered as a pharmaceutical chemist, or as a chemist and druggist under this Bill, or who shall compound or dispense any prescription of any duly qualified medical practitioner containing any medicines of the British Pharmacopœia, except according to the formularies of the said Pharmacopœia, each and every person so offending shall for every such offence be liable, on summary conviction before one or more justices of the peace, to pay a penalty not exceeding ten pounds, and when recovered, such penalties shall be applied to the purposes of this Bill; but nothing in this Bill contained shall extend to, or interfere with, the business of any legally qualified apothecary, or the lawful business of any veterinary surgeon.

14. Upon the decease of any pharmaceutical chemist or chemist and druggist actually in business at the time of his death, it shall be lawful for any executor, administrator, or trustee of the estate of such pharmaceutical chemist, or chemist and druggist, to continue such business, provided such business shall be *bonâ fide* conducted by a pharmaceutical chemist, or chemist and druggist, as the case may be, registered under this Bill.

15. It shall, nevertheless, be lawful, anything to the contrary notwithstanding, for the examiners appointed under this Bill to admit to examination any chemist and druggist being twenty-one years of age, who shall have been continuously at the business as such in Ireland for a term of five years immediately preceding the passing of this Bill, and who shall, within twelve months after it has passed into law, make application in writing for examination to the registrar under this Bill, accompanied with a certificate according to Schedule (C) to this Bill; and every such chemist and druggist who shall have satisfied the examiners as to his knowledge, skill, and competency to carry on and conduct the business of a pharmaceutical chemist or pharmacist, shall receive the certificate of pharmacy from the said examiners, and shall be entitled to be placed on the register of pharmaceutical chemists of Ireland; and the persons so certified shall pay the same fees as other pharmaceutical chemists under this Bill; provided always that in case of rejection the rejected candidate may be re-examined after six months.

16. Any person who has been at business as a chemist and druggist in Ireland before the passing of this Bill shall be entitled to be registered in the list of chemists and druggists of Ireland under this Bill, on producing a certificate according to Schedule (C) of this Bill; but any person who has not been so engaged before the passing of this Bill, shall produce a certificate of being twenty-one years of age, and shall pass a modified examination to be determined on by the Council of the Pharmaceutical Society, in order to entitle him to have his name inserted in the registered list of chemists and druggists of Ireland, for the purposes of this Bill; but registration in this list shall in nowise qualify or empower to compound medical prescriptions.

17. At all general meetings of the Society, it shall be lawful for the Society to make all such by-laws and rules for the advancement of pharmacy and for the good government of the Society as the members present shall in their wisdom, and by a majority of votes, determine, provided always, that said by-laws and rules shall be consonant with, and not contrary to, any of the provisions of this Bill, subject to the approval of the Lord Lieutenant.

18. It is hereby enacted that the exemption of pharmaceutical chemists from service on all juries and inquests, under the Juries Act, 1862, be applicable to the pharmaceutical chemist duly registered under this Bill.

19. This Act may be cited as the Pharmacy Act, Ireland, 187 .

SCHEDULE A.

Scale of Fees for Certificates.

Chemists and Druggists	1 guinea.
Apprentices and Students	2 guineas.
Assistants	3 guineas.
Pharmaceutical Chemists	5 guineas.
The Fee for Registration	5 shillings.

SCHEDULE B.

Name.	Residence.	Date of Registration.
A. B.	Grafton Street, Dublin.	January 10th, 187 .
C. D.	Patrick Street, Cork.	March 4th, 187 .
E. F.	Corn Market, Belfast.	June 15th, 187 .

SCHEDULE C.

Certificate to be signed by a *duly qualified Medical Practitioner* or *Magistrate* respecting a person who was at the business for five years as a Chemist and Druggist, in Ireland, prior to the passing of the Pharmacy Act, Ireland, or was in business as such at the date of the passing of said Act, as the case may require.

To the Registrar appointed under the Pharmacy Act, Ireland, 187 .

I, residing at in the county of hereby certify that I am a duly qualified Medical Practitioner (or Magistrate), and that to my knowledge , residing at , the county of , has been engaged in the business of Chemist and Druggist (for five years continuously) prior to the passing of the Pharmacy Act, Ireland, or at date of the passing of the said Act.

(Signed)

This day of 187

EXAMINATION PAPERS.

At Bow Street Police Court, on Monday, April 5, Samuel Cowap, aged 21, described as a chemist's assistant, residing at 42, Castle Street East, Oxford Street, was charged before Mr. Flowers with inciting one George Austin to steal an examination paper of the Pharmaceutical Society from his employers, Messrs. Stevens and Richardson, printers, of 5, Great Queen Street, Lincoln's Inn Fields. Mr. Douglas Straight, instructed by Messrs. Flux and Co., solicitors to the Pharmaceutical Society, appeared for the prosecution.

In opening the case Mr. Douglas Straight said that the charge against the prisoner was one of inciting Mr. George Austin, who is in the employ of Messrs. Stevens and Richardson, to steal a copy of the examination paper which had been prepared for the Preliminary examination of the Pharmaceutical Society that was to take place that day. As his worship was perhaps aware, all persons who wish to be employed in making up prescriptions are now wisely required to pass certain examinations to prove their efficiency, and it was to obtain a paper of the questions that would be put in the Preliminary examination that the prisoner, acting possibly under the instructions of some third party, committed the offence with which he is charged. In the year 1871 a similar case was brought to that court by the Apothecaries' Company, and sent for trial, the prisoner in that case being afterwards convicted and sentenced to twelve months' imprisonment with hard labour. In the present case, on Thursday last, Mr. Austin, in the employment of Messrs. Stevens and Richardson, who print the examination papers for the Pharmaceutical Society, received a message that a person wished to see him. What took place at that interview Mr. Austin would be called to prove in detail, but what it amounted to was this. The prisoner said: I have a fellow reading with me. He is very backward. I must pass him, and if you can let me have a copy of the paper I will give you half a sovereign. Mr. Austin thought it was very desirable to bring this style of person—who could perhaps place the same temptation in the way of others less able to resist it than himself—to justice, and, therefore, he arranged to take a copy of the examination paper required to some spot, on Saturday, where it could be handed over to the prisoner. This, Mr. Straight said, was his case, and he did not very well see, if these facts were proven, what answer there could be to the charge. Mr. Straight then called

Mr. George Austin, who said: I am employed by Messrs. Stevens and Richardson, of Great Queen Street. They are the printers for the Pharmaceutical Society, and among other things they print the *Pharmaceutical Journal*. They also print the examination papers for the Society. When these papers are printed they are in the custody of Mr. Richardson, one of the partners. To obtain a copy I should have to break open a lock. On Thursday last I was engaged on the *Pharmaceutical Journal*. It was between eight and nine, I think, in the evening. A lad, named Bladon, came up to me and made a communication, in consequence of which I went downstairs. There was no one at the door, but the prisoner was standing opposite under a public-house lamp. On seeing me he crossed over and spoke to me. He asked if I was engaged on the *Pharmaceutical Journal.* I said I was. He then said: Do your employers print the examination papers? I said: Yes. He asked: Can you let me have one? I said: No, I can't. Not knowing what to do, I said: They have not gone to press. He then told me that he was not a spy; that he had not come to spy out, or words to that effect. It had struck me that he was sent by the Pharmaceutical Society to see if I was trustworthy. The prisoner continued: Well, to tell the truth, I will give you half a sovereign if you can get me one of those examination papers. I have a young friend reading with me who is very deficient and can't pass this examination unless I can get one of these papers. I then said to him: Well, you know the risk I run in this matter (I had then made up my mind to let my employers know all that took place). He said: I do, but you can trust me. If you are true to me you will have nothing to fear from me, or words to that effect. I then asked him whether he could make an appointment. I asked if Saturday would do. He assented, and then the spot was fixed, whether by him or by me I don't remember. It was at the corner of the Tottenham Court Road where the omnibuses stop. I don't know which corner. This being settled the prisoner asked me to have a glass, but I refused. We then parted. I then returned to my employment. On the following morning I saw my employer, Mr. Richardson, at eight o'clock, who sent me with a letter to Mr. Richard Bremridge, assistant secretary to the Pharmaceutical Society. I received some instructions from Mr. Bremridge. On the Saturday at one o'clock I again saw Mr. Bremridge, and with him Sergeant Butcher. At four o'clock on this Saturday afternoon, that is the 3rd of April, I went to the corner of Tottenham Court Road, with the examination paper (produced in court). I met the prisoner who said: Are you alone? I said: Yes, but are you alone? for you know the risk I run. He said: Oh, you have nothing to fear. We then went into a public-house where I said to him: Is this for yourself? He said: It is. I asked him: Why did you tell me it was for some one else? He did not answer that but said: I am very well up, but am not confident of passing without the papers, or something to that effect. He made me understand that without those papers he could not pass. He said that the greatest difficulty was in the translation of Cæsar. I said to him: You are not selling me? and he again replied: No; you have nothing to fear. I then asked him whether he could bring me other business, and he then said: I know other students who would be glad to deal with you, but not for this examination. The examination, for which the paper I had given him, was to take place to-day (Monday). I opened the paper and said: That's what you want. Is it not? He said: That's it. He then handed me the half sovereign and I gave him the paper. Detective Butcher, who was at hand, immediately took him into custody.

Mr. Straight said that upon this evidence he should ask for a remand, as it was of great importance to find out, if possible, whether the prisoner had simply obtained the paper for himself, or whether he had acted under the instructions of some other person.

Mr. Flowers remanded the case till to-day (Saturday) at two o'clock.

The prisoner was admitted to bail; himself in £40, and two sureties in £20, or one in £40.

Fatal Explosion whilst Preparing Oxygen Gas.

An inquest on the body of Mr. James S. Marsden, whose death had been occasioned by an explosion which took place in his residence, Tritonville Road, on the 18th March last, was resumed in the schoolhouse, Irishtown, by Dr. Davys, on Saturday, April 3rd.

Mr. J. Rynd, instructed by Mr. J. C. Rynd, appeared for the next of kin of the deceased.

Dr. Boyd, instructed by Mr. George Belas, appeared on behalf of the Apothecaries' Hall of Ireland.

The Coroner, addressing the jury, told them that since they met last Mrs. Marsden, the widow of the deceased, had sufficiently recovered from the injuries which she had sustained by the explosion to be able to attend and give evidence. He wished to ask whether it was admitted by the Apothecaries' Hall that the material from which Mr. Marsden attempted to make gas was procured there.

Dr. Boyd: Most certainly not. The Apothecaries' Hall was served with a notice to attend here, and in deference to that I appear.

Mrs. Maria Anne Marsden, the widow of the deceased, was then sworn. Her hands were bound up in linen. She deposed as follows: Mr. James Marsden was in perfect bodily and mental health on Thursday, the 18th of March; we had our tea early, and then he proceeded to prepare the gas for a magic lantern exhibition in the kitchen; he opened two packages and ground some black and white materials together with a bottle, and then put a small portion of the mixture into a retort; the retort, I think, was made of iron; I was about to remark that the fire was bad, when the explosion took place; the retort had only been a second on the fire; we were both rendered insensible by the effects of the explosion; my husband was aged forty, and was the principal support of our family.

By Mr. Rynd: He was assistant messenger in the Bankruptcy Court.

Miss Charlotte Elizabeth Creighton examined: I live at No. 2, Tritonville Road, the house opposite Mr. Marsden's; I was in his kitchen on the evening of the occurrence; when I came over I found him preparing to make the gas; he took the ingredients out of white papers which he threw into a corner of the grate.

By Mr. Rynd: On one of the packages the words "oxide of manganese" were badly written (paper produced); I positively swear that this is the paper of the package to which I refer.

To the Coroner: The explosion was just like the sound of a cannon, such as is heard when there is artillery practice.

Mr. Edward Clegg examined: I am an apprentice of Simpson and Co., Henry Street; I have been there over two years; I gave a parcel to my brother in our house on the 17th March last; I believe it to contain black oxide of manganese and chlorate of potash—three pounds of the latter and a pound and a half of the former—in separate parcels; I had obtained them at the Apothecaries' Hall myself; Mr. Marsden had asked me to get them there; I did not actually see either of the substances; they were supplied to me there by Mr. Jesson, who, I believe, is a qualified person; the names of the substances were written on each parcel (the witness identified the paper previously produced as that which contained the manganese); the parcels never left my possession until I gave them to my brother; I brought the names of the substances written on a slip of paper to the Apothecaries' Hall, and gave it to Mr. Jesson, saying I was going to dinner, and would call back for the parcels, which I did.

To a Juror: Mr. Marsden himself came to me at Simpson's and asked me to buy the ingredients at the Apothecaries' Hall, as I would get them cheaper there than elsewhere; I wrote down the names immediately; I made no mistake.

To the Coroner: I had not to undergo any examination before I was apprenticed.

Mr. John Robinson examined: I reside at 39, Lower Sackville Street; I am a photographer and certified chemist. I knew Mr. Marsden; he was accustomed to the making of oxygen gas, both professionally and as an amateur, and I considered him competent and intelligent. On the Saturday after the explosion I went to Mr. Marsden's kitchen, having been asked by the family to examine it. I found plenty of the material which was intended to go into the retort, and other material which resulted from the explosion. I believe what caused the explosion to have been the substitution of black antimony for manganese.

A Juror: Did any portion of the mixture remain in the room?

Witness: No; the explosion would have consumed all. [The paper already identified was submitted to the witness.] I consider the discoloration on this paper to have been caused by black antimony.

Mr. George Porte, head master of the Erasmus Smith's school, at No. 43, Great Brunswick Street, deposed: The deceased was my assistant for a great number of years; he was also in the habit, during thirteen years, of making oxygen gas for me, and I considered him perfectly competent to do so. The discoloration on the paper produced is decidedly that of black antimony; the result of the fusion of manganese and the chlorate of potash is a black residuum, while the material left after the explosion of antimony and chlorate of potash would be white. I don't believe it possible that so much of the mixture in question as has been stated (4½ lbs.) could have been put into the crucible, because the latter—which I gave to Mr. Marsden—would not have held it, and also, because if such a quantity had been exploded, there would not have been two stones of the house left together.

Surgeon J. P. Doyle, M.D., of Irishtown, deposed that immediately after the occurrence Mr. Marsden was brought to his house which was not far off. He was able to walk there, but died shortly afterwards from blood-poisoning.

The jury, after a very brief deliberation, found the following verdict:—"That the deceased, James Marsden, aged 40 years, came by his death on the 20th of March, in consequence of injuries accidentally received on the 18th of March from manufacturing oxygen gas, and that the explosion was caused by sulphuret of antimony having been supplied from the Apothecaries' Hall in mistake for manganese.——*Freeman's Journal.*

The Sale of Vermin Killers.—Attempted Suicide.

was charged before Mr. Moreton with having attempted
At Wolverhampton, on Monday last, Samuel Harvey,
to commit suicide.

Police-sergeant Evans said he was called into the prisoner's house on Saturday night, when he found the prisoner vomiting. He fetched Mr. Love, the police surgeon.

Stephen Sibthorpe, assistant to Messrs. Reade, chemists and druggists, Victoria Street, said the prisoner came to Messrs. Reade's shop on Saturday, and purchased a packet of Battle's vermin powder. He knew the face of the prisoner, who said he had frequently purchased the same powder for killing vermin. The defendant signed his name on being supplied, but gave no address. In reply to the Bench, witness said he was aware that the powder contained either strychnine or arsenic.

Mr. Barber said that it was not sufficient for a person to sign his name; he must also give his address, and if unknown to the chemist, he must be introduced by some one whom the chemist did know. This was provided by the last Pharmacy Act, which also set forth that all compounds containing poisonous ingredients mentioned in the schedule of the Act must be labelled "poison" on being sold.

The witness said he did not know positively that Battle's vermin powder contained strychnine. It was simply a supposition.

Mr. Barber: But strychnine is one of the twenty things mentioned in the schedule of the Act.

Witness: But the packet does not say it is strychnine.

Mr. Moreton: The meaning of the Act is so clear that if you repeat sales again like this you will get into trouble.

Witness: We shan't repeat it again.

Captain Segrave said he must ask for a summons against the witness for selling the powder without taking proper precautions.

Mr. Moreton: You had better leave that matter alone for the present.

Mr. J. H. Love said he was called to see the prisoner on Saturday evening. He was vomiting, and was also in a profuse perspiration, and complained of great pains. Witness considered that he had taken something containing strychnine, as he was suffering from tetanic spasms. Battle's vermin powder contained strychnine. The mixture varied from one to three grains of strychnine, of which half a grain would be sufficient to kill a person.

The prisoner's wife, on being called, stated that her husband had been drinking heavily of late, through which he had lost his situation.

A fellow-workman of the prisoner was bound over for the prisoner's good behaviour for the next six months.—*Midland Counties Evening Express.*

The Sale of Methylated Spirit.

On Thursday, at the Southwark Police Court, Mr. Charles Downs, surgeon, 13, White Street, Borough, was summoned by the Excise for selling methylated spirits without a licence.—Thomas Winslow, an officer of the Excise, said that on the 5th of February he went to the defendant's surgery and asked for half a pint of methylated spirits. The assistant served him and took the money.—The Defendant said that his was an open surgery, and he only kept a small quantity for use. He never sold any at any time. When the Excise officer came for the spirit his assistant, who had only been three weeks in his service, let him have all he had, which was very little beyond a quartern, as he was not aware of the law.—A long discussion took place as to the liability of Mr. Downs for the act of his assistant, and Mr. Powell cited several cases from the Law Reports to support the complaint, and added that if otherwise they would have great difficulty in enforcing the revenue laws.—Mr. Benson said it had not been shown to his satisfaction that defendant knowingly sold the spirit, therefore he dismissed the summons.

Messrs. Hardy and Simpson, chemists, Great Dover Street, Borough, were summoned for a like offence.—Thomas Winslow said that on the same day Mr. Hardy served him with half a pint of methylated spirits. He was not licensed to sell it.—The Defendants having pleaded guilty, Mr. Benson fined them in the mitigated penalty of £12 10s.

Ignoramus.—The ordinary tests for strychnia as described in works on chemistry; for instance, Attfield's 'Manual.'

"*Nitrogen*" and "*A Chemist and Druggist*" are referred to the rule respecting anonymous communications.

S. Tabor.—Your letter and enclosure have been handed to the advertisement agents, Messrs. Churchill.

"*Juvenis.*"—You will find instructions for the drying and preserving of plants in the *Pharmaceutical Journal,* for March 21, 1874, p. 754.

W. J. B. will find recipes for "Brilliantine," in vol. i. of the present series of this Journal, p. 437.

C. Lowe and Co.—The receipt of your letter was acknowledged in the Journal for March 20.

R. E. J.—By referring to the report in this number of the Journal, you will perceive that your letter has been written under some misapprehension as to the facts of the case.

In consequence of the length to which the official reports extend we are compelled to postpone the publication of several communications.

Communications, Letters, etc., have been received from Dr. Craig, Professor Flückiger, Messrs. J. Abraham, A. W. Shakespeare, Holmes, W. Gunn, E. de T. Collins, J. J. Jenkins, "Palt," "Vinegar," W. B. C., W. W. W.

SOLID AND LIQUID JAPANESE OIL OF PEPPERMINT.*

BY JOHN MACKAY.

Early in the present session some remarks were made at one of the evening meetings in London by Mr. Moss, F.C.S., on Japanese oil of peppermint.

The subject appeared to me to be of considerable interest, and I made efforts to obtain specimens of both liquid and solid oils. These are now on the table, and have been kindly supplied by the same parties (Cyriax and Farries) who gave them to Mr. Moss. As I am permitted to dispose of them in any way I think fit, it gives me much pleasure to hand them over to our museum.

Let me now place before you the principal facts known about these oils—chiefly derived from the paper already referred to and other sources.

1. The oils appear to have come over from Japan in cylindrical tin canisters, and up to the present time the quantities received in this country have not been intended for sale, being small, and sent more for curiosity and for specimens.

2. The solid portion, though called crystallized oil of peppermint, appears to be simply a deposit from the original liquid oil, probably at a low temperature.

3. About thirteen years ago a memoir on crystallized oil of peppermint was presented to the London Chemical Society by Oppenheim. This chemist speaks of the article as coming over here in considerable quantity, adulterated to the extent of 10 or 20 per cent. with sulphate of magnesium. In this statement, however, there seems to be some error, because after many inquiries, no traces can be found of this article being known as an article of commerce, while it was equally unknown to chemists. In regard to adulteration there is no resemblance between the two substances,—I mean the one referred to by Oppenheim and that now under notice—because though the crystals do resemble in appearance the so-called adulterating substance, there is not the slightest trace of its presence, a chemical examination indicating, that the deposition is as pure as the oil from which it has been thrown down.

4. Dr. Attfield refers to peppermint camphor under the name of menthene, believing it to be the hydrocarbon found more or less in nearly all varieties of peppermint oil.

5. From the numerous experiments which have been made, such as the fusing and boiling point, solubility (though very sparing) in water, ether, alcohol, bisulphide of carbon, fatty and essential oils, etc., it appears that the substance now shown is in all respects identical with that submitted by Oppenheim in 1862 to the Chemical Society, but free from any adulterating ingredient.

6. Dumas, as well as Oppenheim, appears to have operated on peppermint camphor. The result of his examination corresponded with that of Oppenheim and Attfield. Dumas used the crystals obtained from some variety of American oil, and found the formula to be $C_{10}H_{20}O$, precisely the composition given by the other chemists, and further confirmed by Mr. Hanbury in his 'Pharmacographia.'

So much for the solid oil and its known history. Before remarking further on its solubility, or comparing it with the liquid, let me notice the use to which a similar, if not the identical preparation has been, and is, I understand, still put to in some foreign countries.

About five years ago, Dr. A. Wright communicated to the *Lancet* that when in China he became acquainted with the fact that the natives, when suffering from facial neuralgia, applied oil of peppermint to the seat of pain by means of a camel hair pencil, and with decided success.

In 1871, Mr. D. Hanbury stated in the *Pharmaceutical Journal* that oil of peppermint was distilled at Canton, though unacquainted with the plant used for its production.

Some months thereafter Professor Flückiger referred to a notice which had appeared in the *American Journal of Pharmacy* confirming the use by the Chinese of the oil in neuralgic cases, stating further, that the oil was much used for this purpose in San Francisco and elsewhere, the oil being put up in small ℥ss. bottles, and sold as "Chinese Medicine." For this small quantity one dollar was charged, and the label had printed on it "*Fook-chang-Yong*," with the name of the seller. Professor Flückiger believed the specimen he saw to be good American or English oil, although the dealers in San Francisco declared it to be imported direct from Canton, which of course it might have been. A few drops of this oil Professor Flückiger placed on a glass slide, and in a few hours it yielded crystals of camphor in all respects similar to those he had observed in the Japanese oil. So far, then, as we know, there is but little difference between these two foreign oils, Chinese and Japanese, although it is alleged that in California the former becomes solid in cold weather, while the American or English as a rule do not alter, although in some kinds of oil there may be separated, when subjected to cold, a portion of camphor. The following is what appears on this subject in the 'Pharmacographia' by Professor Flückiger and Mr. D. Hanbury:—

"When oil of peppermint is cooled to 4° C. it sometimes deposits colourless hexagonal crystals of peppermint camphor $C_{10}H_{18}+H_2O$, called also menthol. This camphor, the deposit of which in the oil we have not observed, boils at 210° C. and possesses the odour of the crude oil. The properties of menthol contained in oils of different origin is very variable. Pure crystallized menthol is sometimes found in commerce under the name of Chinese oil of peppermint."

There can, therefore, be very little doubt that menthol, a solid Chinese oil of peppermint, resembles in all its properties the solid portion of Japanese oil, obtained in all probability by submitting the oil to a low temperature, by which all the solid portion is obtained. Nor can it be doubted that chemically, this menthol closely resembles, nay is in all respects the same as the peppermint camphor obtained from our own or American oil, and that in fact, both may be named a monatomic alcohol, menthylic alcohol or hydrate of menthyl being as already stated represented by $C_{10}H_{18}+H_2O$.

In connection with the use of the oil of peppermint in neuralgic cases, I received the following note from Messrs. Frazer and Green, of Glasgow, which will tell its own tale. I may premise the note was written in consequence of receiving one of the circulars announcing that this paper was to be read.

* Read at a meeting of the North British Branch of the Pharmaceutical Society of Great Britain, March 26th, 1875.

113, Buchanan Street, Glasgow.
March 25th, 1875.

John Mackay, Esq.,

Dear Sir,—We had an order some weeks since for three bottles of medicine which we have now no doubt but that it is the Japanese liquid oil of peppermint. Our customer could give no name;—he gave us a small flat bottle with a label printed in Chinese looking characters, the bottle being enclosed in a small paper box. We tried London and could hear of nothing like it except at Messrs. Savory and Moore's, but theirs is the *solid* article. Our customer wishes the liquid. It is used for neuralgia—a drop being rubbed on the affected part. Our order is for three bottles. Can you help us in the matter?

Yours truly,
Frazer and Green.

The following are a few characteristics of the liquid Japanese oil:—

It is soluble in any quantity of ordinary spirit of wine, 56° O.P., and at ordinary temperatures.

The mixture I now submit contains one part of the oil in eight parts of rectified spirit. It dissolves very readily in any proportion and makes a clear solution, and that now shown will give some idea of its behaviour when employed for making the common essence. In comparison with this, I now place two others, one is made from good American, and the other from Mitcham oil of peppermint, and in exactly similar proportions. For strength, flavour, and aroma, the English is undoubtedly the best, then follows the Japanese, and lastly the American.

The liquid oil has the power of dissolving the solid or crystalline oil. With the aid of a gentle heat the proportions are one to four. Here is such a solution, and although no deposition of crystals has taken place in cooling, I have no doubt if submitted to cold, the crystals would be regained.

The solid oil is also capable of solution in ordinary spirit in the proportion of one to two, and without the aid of heat, simply by rubbing in a mortar. I submit such a solution, but it will not compare in point of flavour with the fluid oil. In order that they may be fairly tried I have added some spirit so as to make the strength one to eight as in the other solutions.

Of course one of the most important elements in connection with this subject is the cost of the oil as compared with others in the market. As I have already stated the small quantities as yet sent over are more for samples, and as something rare, than for sale. The firm already referred to have, however, written me that 70 lbs. weight of each kind are coming over soon, and they promise when this lot does arrive to give me notice stating the commercial value of solid and liquid. As their memorandum bears date of 13th March, we may expect ere long to know price and value.

I may further state, that in submitting the solid oil to heat it melts at a temperature of about 100° F. but on cooling it resolidifies. Of this you have a fair example in what I now show in the test tube.

Both the samples seem to me quite free from any adulteration whatever, and specially so from the turpentine smell, which many of the foreign oils of peppermint have. The solution of the solid oil, though pungent to the palate, is disagreeable and wanting in the aroma and flavour which all fine peppermint oil possesses in such a remarkable degree.

If moderate in price and supplied in sufficient quantities, I think it very likely that the liquid Japanese oil may come into demand for confectionery and other purposes, as the samples of liquid oil now submitted give fair promise of the Japanese becoming a competitor with any other English or American oil at present to be found in the market.

CHEMICAL EXAMINATION OF JABORANDI.*

(Pilocarpus pennatifolius ?)

BY M. BYASSON.
